A DYNAMICAL MODEL FOR MULTILAYERED PLATES
WITH INDEPENDENT SHEAR DEFORMATIONS

BY

SCOTT W. HANSEN

Department of Mathematics, Iowa State University, Ames, Iowa

Abstract. In this paper a dynamic model for an n-layered plate is developed based
upon the assumptions of Reissner-Mindlin plate theory. Each plate layer is assumed to
be transversely isotropic, transversely homogeneous and of a uniform thickness; however,
no symmetry in the material properties or thicknesses of each plate is assumed. The
layers are assumed to be perfectly bonded so that no slip occurs along the interface. No
additional a priori kinematic restrictions are imposed upon the motion of the plates.
The equations of motion are derived by the principle of virtual work. Existence and
uniqueness results are obtained. In the case where the layers are symmetric we show
that all solutions decouple into a bending solution (with antisymmetric displacements
about the mid-plane) and an in-plane solution (with symmetric displacements).

1. Introduction. The first model for a thin, multilayered plate that includes the
effects of transverse shear deformation is probably due to Reissner [11], where a static
model is developed for a sandwich plate consisting of an inner core bonded to two sym-
metric face plates. Since then, numerous dynamic models for multilayered materials
based upon similar ideas have been proposed (see, e.g., [1], [3], [4], [8], [14], [15] and
the references therein). In many of these models (often referred to as constrained layer
models) the inner core is assumed to be much more flexible than the face material so
that bending stresses can be ignored within the core and the transverse shear deforma-
tions can be assumed negligible within the face plates. Thus, in the usual approach to
modeling sandwich plates, the outer layers are modeled by plates that allow little or
no shear while the inner layer is modeled as a material in which only shear stresses are
considered relevant. From an applications viewpoint, a goal has been to identify effec-
tive elastic moduli for the composite plate so that a low-order system involving only the
transverse displacement (or possibly transverse displacement and effective rotations) can
be obtained. In order to accomplish this, the number of degrees of freedom of a plate
element are artificially reduced by relating the stresses and/or strains in each layer with
one another.

In this paper we develop a model for the motion of a multilayered plate that allows independent shear rotations in each layer. Each plate layer is assumed to be transversely isotropic, homogeneous in the transverse direction and of a uniform thickness; however, the material properties and thicknesses of each layer can be different. Each layer is modeled under the assumptions of Reissner-Mindlin plate theory [9, 10, 11], i.e., within each layer the in-plane displacements vary linearly with respect to the transverse coordinate, and the transverse normal stress vanishes throughout the thickness. The surfaces of each layer are perfectly bonded so that no slip occurs along the interfaces; however, a main point is that we do not impose additional a priori kinematic restrictions that couple stresses and/or strains of each layer with one another.

The equations of motion are derived through the principle of virtual work, and the modifications needed to include strain-rate damping are discussed. The resulting system is shown to be well-posed in an appropriate function space.

In the case where the layers are symmetric about the center sheet of the plate (that is, the thicknesses, densities and elastic parameters are symmetric with respect to the middle layer or middle interface, as the case may be) we show that the motions decouple in a bending solution, with displacements that are antisymmetric about the center sheet and a stretching solution, with displacements that are symmetric about the center sheet. This type of decoupling has been observed in three-dimensional plate theories as well [13].

A similar model is obtained in [3], where the equations for a symmetric three-layer beam are derived under the assumption that the motion is antisymmetric about the centerline of the beam and Poisson effects are negligible. A fourth-order beam model then is obtained when continuity of shear stresses across the interfaces is imposed and rotational inertia is ignored. As mentioned, in the symmetric case we obtain solutions with antisymmetric displacements about the center sheet; however, this is due to the decoupling and is not imposed a priori. The assumption of shear stress continuity along the interfaces leads to a model in which these stresses are constant throughout the thickness and is not assumed here.

2. Basic assumptions. Our plate consists of n plate layers that occupy the region \( \Omega \times (0, h) \) at equilibrium, where \( \Omega \) is a bounded domain in \( \mathbb{R}^2 \) with sufficiently smooth (say \( C^1 \)) boundary \( \Gamma \). Let

\[ 0 = z_0 < z_1 < \cdots < z_{n-1} < z_n = h, \quad h_i = z_i - z_{i-1}, \quad i = 1, 2, \ldots, n. \]

We use the rectangular coordinates \( \bar{x} = \{x_1, x_2\} \) to denote points in \( \Omega \) and \( x = \{\bar{x}, x_3\} = \{x_1, x_2, x_3\} \) to denote points in \( Q = \bigcup_{i=1}^n Q_i \), where

\[ Q_i = \Omega \times (z_{i-1}, z_i), \quad i = 1, 2, \ldots, n. \]

For \( x \in Q \) let \( U(x) = \{U_1, U_2, U_3\}(x) \) denote the displacement vector of the point which, when the plate is in equilibrium, has coordinates \( x = \{x_1, x_2, x_3\} \). (We suppress all time dependence where there is no possibility of confusion.) In addition, let us define \( u^i = \{u^i_1, u^i_2\} \) and \( u^j_3 \), \( i = 0, 1, 2, \ldots, n \), by

\[ u^j_3(\bar{x}) = U_j(\bar{x}, z_i), \quad j = 1, 2, 3, \forall \bar{x} \in \Omega. \]
Throughout this paper we will continue to reserve the index \( i \) to refer to the particular layer or interface within the composite plate. For vector quantities whose components vary from layer to layer, the index \( i \) will be superscripted, while for scalar quantities the \( i \) will be subscripted.

2.1. Stress-strain relations. Let \( \sigma_{jk}, \varepsilon_{jk} \ (j, k = 1, 2, 3) \) denote the stress and strain tensors, respectively. For a small displacement theory we assume

\[
\sigma_{ij} = \frac{1}{2} \left( \frac{\partial U_j}{\partial x_i} + \frac{\partial U_i}{\partial x_j} \right), \quad \forall x \in Q. \tag{2.1}
\]

For a homogeneous, transversely isotropic material we have within each layer (see Reissner, [12])

\[
\begin{align*}
\varepsilon_{11} &= \frac{1}{E} \sigma_{11} - \frac{\nu}{E} \sigma_{22} - \frac{\nu}{\sqrt{E_E}} \sigma_{33}, \\
\varepsilon_{22} &= -\frac{\nu}{E} \sigma_{11} + \frac{1}{E} \sigma_{22} - \frac{\nu}{\sqrt{E_E}} \sigma_{33}, \\
\varepsilon_{33} &= -\frac{\nu}{\sqrt{E_E}} \sigma_{11} - \frac{\nu}{\sqrt{E_E}} \sigma_{22} + \frac{1}{E} \sigma_{33}, \\
\varepsilon_{13} &= \frac{1}{2G_z} \sigma_{13}, \\
\varepsilon_{23} &= \frac{1}{2G_z} \sigma_{23},
\end{align*}
\]

where \( E, E_z \) denote the Young's moduli (the \( z \) subscript refers to the transverse direction), \( \nu, \nu_z \) denote the Poisson's ratios, \( E/(2(1 + \nu)) \) denotes the in-plane shear modulus and \( G_z \) denotes the transverse shear modulus. All the elastic moduli are allowed to depend upon the coordinate \( x \) and the layer \( i \) (but otherwise are independent of \( x_3 \)) and are assumed to be bounded above and below by positive numbers. The Poisson's ratios are less than \( 1/2 \). The isotropic case is obtained from (2.2) by setting \( E_z = E, \nu_z = \nu, \) and \( G_z = E/(2(1 + \nu)) \).

Following Mindlin's approach [9], \( \varepsilon_{33} \) is assumed to be negligible so that \( \varepsilon_{33} \) may be expressed in terms of the other principle strains:

\[
\varepsilon_{33} = \frac{-\nu_z \sqrt{E}}{(1 - \nu) \sqrt{E_z}} (\varepsilon_{11} + \varepsilon_{22}). \tag{2.3}
\]

From (2.2) and (2.3) we have

\[
\begin{align*}
\sigma_{11} &= \frac{E}{1-\nu^2} (\varepsilon_{11} + \nu \varepsilon_{22}), \\
\sigma_{22} &= \frac{E}{1-\nu^2} (\nu \varepsilon_{11} + \varepsilon_{22}), \\
\sigma_{33} &= 0, \\
\sigma_{13} &= \frac{E}{1-\nu^2} \varepsilon_{13}, \\
\sigma_{23} &= \frac{E}{1-\nu^2} \varepsilon_{23},
\end{align*}
\]

2.2. Displacement assumption. To obtain a two-dimensional plate model, in addition to (2.4), some assumptions are needed on either the form of the displacements or the form of the stresses as a function of the transverse coordinate. Reissner's approach [10, 11] is based on first-order approximations for the stresses while Mindlin's approach [9] is based on linear displacement assumptions. For example, Reissner assumes \( \sigma_{13} \) and \( \sigma_{23} \) to be parabolic, in such a way that these stresses vanish on the surfaces of the plate. In Mindlin's approach \( \varepsilon_{13} \) and \( \varepsilon_{23} \) are assumed to be constant throughout the thickness (consequently the stresses will not in general vanish on the surfaces); however, a shear correction coefficient \( \kappa \) is incorporated in (2.4) to compensate:

\[
\sigma_{13} = 2G \varepsilon_{13}, \quad \sigma_{23} = 2G \varepsilon_{23}, \quad G = \kappa G_z. \tag{2.5}
\]

When \( \kappa = 5/6 \), to highest order in the thickness, both approaches lead to the same two-dimensional plate theory, although the displacement variables have slightly different
meanings with respect to the transverse direction (see Reissner’s survey article [12] and also [9] for comparisons of these plate theories).

In our approach to modeling the multilayer plate, we assume (2.4) with the correction (2.5) in conjunction with linear displacement assumptions in each layer. In addition, the no-slip condition imposes continuity of the displacements along the interfaces so that (usually) corners exist at the interfaces. Thus, by specifying the displacements $u^i(\hat{x}), u^j(\hat{x}), i = 0,1,2,\ldots, n$ at each $\hat{x}$ in $\Omega$, the displacement $U$ is uniquely determined. The assumption that the transverse normal stresses vanish throughout the thickness implies

$$w(\hat{x}) \equiv u^0_3(\hat{x}) = u^1_3(\hat{x}) = \cdots = u^n_3(\hat{x}) \quad \forall \hat{x} \in \Omega.$$ 

Thus we find that each filament that is originally orthogonal to the surfaces has $2n + 3$ degrees of freedom: $w, u^0, \ldots, u^n$.

For $i = 1,2,\ldots, n$ define $\psi^i = \{\psi^i_1, \psi^i_2\}$, $\varphi^i = \{\varphi^i_1, \varphi^i_2\}$, and $v^i = \{v^i_1, v^i_2\}$ by

$$\psi^i = \frac{u^i - u^{i-1}}{h_i}, \quad \varphi^i = \psi^i + (\nabla w)^T, \quad v^i = \frac{u^{i-1} + u^i}{2}. \quad (2.6)$$

The components $\psi^i_j$ of $\psi^i$ can be viewed as the total rotation angles of filaments within the $i$th layer in the $(x_j, x_3)$-plane (with negative orientation). The components of $\varphi$ represent the (small angle approximation for the) shear angles within each layer. (See Figure 1.) The components of $v^i$ represent the in-plane displacements of the midplanes of the $i$th layer.

Define

$$\hat{z}_i = (z_{i-1} + z_i)/2.$$
The displacements within the $i$th layer can be written in terms of the translations $v^i$ and total rotation angles $\psi^i$ as
\[
\begin{align*}
U_1(x, x_3) &= v_1^i(x) + (x_3 - \hat{z}_i)\psi_1^i(x), & z_{i-1} < x_3 < z_i, \\
U_2(x, x_3) &= v_2^i(x) + (x_3 - \hat{z}_i)\psi_2^i(x), & z_{i-1} < x_3 < z_i, \\
U_3(x, x_3) &= w(x), & z_{i-1} < x_3 < z_i.
\end{align*}
\tag{2.7}
\]

Note that continuity of the displacements along the interfaces follows from the way that $\phi^i$ and $v^i$, $i = 1, 2, \ldots, n$, are related in (2.6).

Substituting (2.7) into (2.1) gives an expression for the strain within the $i$th layer:
\[
\begin{align*}
\varepsilon_{11} &= \frac{\partial v_1^i}{\partial x_1} + (x_3 - \hat{z}_i)\frac{\partial \psi_1^i}{\partial x_1}, \\
\varepsilon_{22} &= \frac{\partial v_2^i}{\partial x_2} + (x_3 - \hat{z}_i)\frac{\partial \psi_2^i}{\partial x_2}, \\
\varepsilon_{12} &= \frac{1}{2} \left[ \frac{\partial v_1^i}{\partial x_2} + \frac{\partial v_2^i}{\partial x_1} + (x_3 - \hat{z}_i) \left( \frac{\partial \psi_1^i}{\partial x_2} + \frac{\partial \psi_2^i}{\partial x_1} \right) \right], \\
\varepsilon_{13} &= \frac{1}{2} (\frac{\partial v_1^i}{\partial x_3}), \\
\varepsilon_{23} &= \frac{1}{2} (\frac{\partial v_2^i}{\partial x_3}).
\end{align*}
\tag{2.8}
\]

Since we have assumed $\sigma_{33}$ to be negligible we may assume (for the purpose of calculating the energy) that
\[
\varepsilon_{33} = 0.
\]

2.3. Strain and kinetic energy. The strain energy $\mathcal{P} = \sum_{i=1}^{n} \mathcal{P}_i$ for the composite plate is given by
\[
\mathcal{P}_i = \frac{1}{2} \int_{Q_i} \sum_{j,k=1}^{3} \varepsilon_{jk} \sigma_{jk} \, d\vec{x} \, dx_3.
\]

From (2.4) and (2.5) $\mathcal{P}_i$ can be written in terms of the strains:
\[
\mathcal{P}_i = \frac{1}{2} \int_{Q_i} \frac{E}{(1 - \nu^2)} \left( \varepsilon_{11}^2 + 2\nu\varepsilon_{11}\varepsilon_{22} + \varepsilon_{22}^2 + 2(1 - \nu)\varepsilon_{12}^2 \right) + 4G(\varepsilon_{13}^2 + \varepsilon_{23}^2) \, d\vec{x} \, dx_3.
\]

From (2.8) we obtain
\[
\mathcal{P}_i = \frac{h_i^3}{2} \int_{\Omega} D_i \left[ \left( \frac{\partial v_1^i}{\partial x_1} \right)^2 + \left( \frac{\partial v_2^i}{\partial x_2} \right)^2 + 2\nu_i \left( \frac{\partial v_1^i}{\partial x_2} \frac{\partial v_2^i}{\partial x_1} \right)^2 \right] \, d\vec{x}
\]
\[
+ \frac{h_i}{2} \int_{\Omega} 12D_i \left[ \left( \frac{\partial v_1^i}{\partial x_1} \right)^2 + \left( \frac{\partial v_2^i}{\partial x_2} \right)^2 + 2\nu_i \left( \frac{\partial v_1^i}{\partial x_1} \frac{\partial v_2^i}{\partial x_2} \right) \right]
\]
\[
+ \left( \frac{1 - \nu_i}{2} \right) \left( \frac{\partial v_1^i}{\partial x_2} + \frac{\partial v_2^i}{\partial x_1} \right)^2 \right] \right] + G_i((\varphi_1^i)^2 + (\varphi_2^i)^2) \, d\vec{x}
\]
\]

where $\nu_i = \nu(\cdot, i), G_i = G(\cdot, i)$, and $D_i = E(\cdot, i)/(12(1 - \nu^2))$. $D_i h_i^3$ is the modulus of flexural rigidity (see [6, p. 10]) for the $i$th layer and $h_i G_i$ is the modulus of elasticity in shear (see [6, p. 14]) for the $i$th layer.
The kinetic energy $K = \sum_{i=1}^{n} K_i$ is defined by

$$K_i = \frac{1}{2} \int_{Q_i} \rho_i (\dot{U}_1^2 + \dot{U}_2^2 + \dot{U}_3^2) \, dx \, dx_3,$$

where $\dot{\cdot} = d/dt$ and $\rho_i = \rho_i(x) > \rho > 0$ denotes the mass density per unit volume within the $i$th layer.

We find

$$K_i = \frac{1}{2} \int_{\Omega} \rho_i h_i (\dot{\psi})^2 + \frac{\rho_i h_i^3}{12} (\dot{\psi}^i \cdot \dot{\psi}^i) + \rho_i h_i (\dot{\phi}^i \cdot \dot{\phi}^i) \, dx,$$

where the “dot product” denotes the usual scalar product on $\mathbb{R}^2$.

2.4. Work. To set ideas we will assume that the plate is clamped on a portion of its edge $\Gamma_0 \subset \Gamma$ of positive measure. Furthermore, denote $\Gamma_1 = \Gamma - \Gamma_0$.

Now assume the composite plate is subject to a volume distribution of forces $(f_1, f_2, f_3)$ and a distribution of forces $(\tilde{g}_1, \tilde{g}_2, \tilde{g}_3)$ along $\Gamma_1$. The work done on the plate by these forces is $W = \sum_{i=1}^{n} W_i$, where

$$W_i = \int_{Q_i} \sum_{j=1,2,3} f_j U_j \, dx \, dx_3 + \int_{\Gamma_i} \sum_{j=1,2,3} \tilde{g}_j U_j \, d\Gamma \, dx_3.$$

For $x \in \Omega$ and $s \in \Gamma_1$ denote

$$f_3(x) = \int_0^h f_3(x, x_3) \, dx_3, \quad g_3(s) = \int_0^h g_3(s, x_3) \, dx_3, \quad (2.9)$$

and for $i = 1, 2, \ldots, n$,

$$f_j^i(x) = \int_{z_{i-1}}^{z_i} f_j \, dx_3, \quad M_j^i(x) = \int_{z_{i-1}}^{z_i} (x_3 - z_i) f_j \, dx_3, \quad j = 1, 2,$$

$$g_j^i(s) = \int_{z_{i-1}}^{z_i} g_j \, dx_3, \quad m_j^i(s) = \int_{z_{i-1}}^{z_i} (x_3 - z_i) g_j \, dx_3, \quad j = 1, 2. \quad (2.10)$$

Furthermore, for $i = 1, 2, \ldots$ denote $f^i = \{f_1^i, f_2^i\}$, $M^i = \{M_1^i, M_2^i\}$, and likewise for $g^i$ and $m^i$. Due to the assumptions in (2.7), the expression for the work can be expressed in terms of the resultants in (2.9)-(2.10) and we obtain

$$W = \int_{\Omega} w f_3 + \sum_{i=1}^{n} (\psi^i \cdot M^i + v^i \cdot f^i) \, dx + \int_{\Gamma_1} w g_3 + \sum_{i=1}^{n} (\psi^i \cdot m^i + v^i \cdot g^i) \, d\Gamma. \quad (2.11)$$

We will also need to refer to the force resultants along the interfaces. If in place of (2.10) we define $p_j^i(x)$ and $q_j^i(s)$, $i = 0, 1, 2, \ldots, n$, $j = 1, 2$ to be the effective resultant forces acting at the points $\{x, z_i\} (x \in \Omega)$ and $\{s, z_i\} (s \in \Gamma_1)$ then (2.11) takes the form

$$W = \int_{\Omega} w f_3 + \sum_{i=1}^{n} (u^i \cdot p^i) \, dx + \int_{\Gamma_1} w g_3 + \sum_{i=1}^{n} (u^i \cdot q^i) \, d\Gamma. \quad (2.12)$$

These resultant forces used in (2.12) are related to those in (2.10) by

$$p^0 = f^1/2 - M^1/h_1,$$

$$p^i = (f^i + f^{i+1})/2 + M^i/h_i - M^{i+1}/h_{i+1}, \quad i = 1, 2, \ldots, n - 1,$$

$$p^n = f^n/2 + M^n/h_n, \quad (2.13)$$

and the $q^i$ are related to $g^i$ and $m^i$ in the same way.
3. Equations of motion. The Lagrangian $\mathcal{L}$ on $(0, T)$ is defined by

$$\mathcal{L} = \int_0^T (\mathcal{K}(t) + \mathcal{W}(t) - \mathcal{P}(t)) \, dt.$$

According to the principle of virtual work, the solution trajectory is the trajectory that renders stationary the Lagrangian under all kinematically admissible displacements. In this section we use this approach to derive the weak form of the equations of motion and then determine the associated boundary value problem.

First however, some additional notation is called for.

3.1. Notation. Let us first define the following $n$ by $n$ matrices:

$$h = \text{diag}(h_1, h_2, \ldots, h_n), \quad D = \text{diag}(D_1, D_2, \ldots, D_n),$$
$$\rho = \text{diag}(\rho_1, \rho_2, \ldots, \rho_n), \quad G = \text{diag}(G_1, G_2, \ldots, G_n).$$

Let $\psi, \varphi, v, f, g, M,$ and $m$ be the $n$ by $2$ matrices defined by

$$(\psi)_{ij} = \psi^i_j, \quad i = 1, 2, \ldots, n, \quad j = 1, 2,$$
and so forth for $\varphi, v, f, g, M,$ and $m$. Also let $u, p, q$ denote the $n + 1$ by $2$ matrices defined by

$$(u)_{ij} = u^i_j, \quad i = 0, 1, 2, \ldots, n, \quad j = 1, 2,$$
and likewise for $p$ and $q$ ($p^i_j$ and $q^i_j$ are defined by (2.13)).

If we let $S^+$ and $S^-$ denote the $n$ by $n + 1$ matrices defined by

$$S^+ \{y_0, y_1, \ldots, y_n\}^T = \{y_1, y_2, \ldots, y_n\}^T,$$
$$S^- \{y_0, y_1, \ldots, y_n\}^T = \{y_0, y_1, \ldots, y_{n-1}\}^T,$$
then $\psi$ and $v$ are given in terms of $u$ as

$$\psi = h^-(S^+ - S^-)u, \quad v = 2^{-1}(S^+ + S^-)u,$$
and $\varphi$ is given in terms of $u$ and $w$ by

$$\varphi = \psi + \{\nabla w, \nabla w, \ldots, \nabla w\}^T \triangleq \psi + \nabla w,$$
where $\nabla w$ repeats $n$ times.

If $\theta$ and $\xi$ are matrices in $\mathbb{R}^{lm}$, by $\theta \cdot \xi$ we mean the scalar product in $\mathbb{R}^{lm}$. We will also denote

$$(\theta, \xi)_\Omega = \int_\Omega \theta \cdot \xi \, d\mathbf{x}, \quad (\theta, \xi)_{\Gamma_1} = \int_{\Gamma_1} \theta \cdot \xi \, d\Gamma.$$

3.2. Weak form of equations of motion. The expressions for the kinetic and potential energy and work can be rewritten as

$$\mathcal{K}(t) = \ddot{c}(\psi, \dot{\psi}, \dot{\psi}; \dot{\psi}, \ddot{\psi}, \dddot{\psi})/2,$$
$$\mathcal{P}(t) = \ddot{a}(v, \psi, \varphi; v, \psi, \varphi)/2,$$
$$\mathcal{W}(t) = (\psi, M)_\Omega + (v, f)_\Omega + (w, f_3)_\Omega + (\psi, m)_{\Gamma_1} + (v, g)_{\Gamma_1} + (w, g_3)_{\Gamma_1},$$
where \( \tilde{c}(\cdot; \cdot) \) and \( \tilde{a}(\cdot; \cdot) \) denote the bilinear forms

\[
\tilde{c}(\psi, v, w; \dot{\psi}, \dot{v}, \dot{w}) = ((h \cdot \rho)w, \dot{w})_\Omega + ((\rho h^3/12)\psi, \dot{\psi})_\Omega + (h\rho v, \dot{v})_\Omega,
\]

\[
\tilde{a}(\psi, v, \varphi; \dot{\psi}, \dot{v}, \dot{\varphi}) = \tilde{a}_0(h^3\psi; \dot{\psi}) + 12\tilde{a}_0(hv; \dot{v}) + \tilde{a}_1(\varphi; \dot{\varphi}),
\]

\[
\tilde{a}_0(\psi; \dot{\psi}) = \sum_{i=1}^n \tilde{a}_0^i(\psi^i; \dot{\psi}^i),
\]

\[
\tilde{a}_0^i(\psi^i; \dot{\psi}^i) = \left( D_i \frac{\partial \psi^i_1}{\partial x_1}, \frac{\partial \dot{\psi}^i_1}{\partial x_1} \right)_\Omega + \left( D_i \frac{\partial \psi^i_2}{\partial x_2}, \frac{\partial \dot{\psi}^i_2}{\partial x_2} \right)_\Omega
\]

\[
+ \left( (1 - \nu_i) D_i \left( \frac{\partial \psi^i_1}{\partial x_2} + \frac{\partial \psi^i_2}{\partial x_1} \right), \left( \frac{\partial \dot{\psi}^i_1}{\partial x_2} + \frac{\partial \dot{\psi}^i_2}{\partial x_1} \right) \right)_\Omega,
\]

\[
\tilde{a}_1(\varphi; \dot{\varphi}) = (Gh\varphi, \dot{\varphi})_\Omega.
\]

Let \( \{\hat{u}, \hat{w}\} = \{\hat{u}^0, \hat{u}_1, \ldots, \hat{u}^n, \hat{w}\} \) denote a test function on \( \Omega \times (0, T) \) (with dimensionality matching that of \( \{u, w\} \)) for which

\[
\{\hat{u}, \hat{w}\} = \left\{ \frac{\partial \hat{u}}{\partial n}, \frac{\partial \hat{w}}{\partial n} \right\} = 0 \quad \text{on } \Gamma_0 \times (0, T),
\]

\[
\{\hat{u}, \hat{w}\}|_{t=0} = \frac{\partial}{\partial t} \{\hat{u}, \hat{w}\}|_{t=0} = \{\hat{u}, \hat{w}\}|_{t=T} = 0 \quad \text{in } \Omega,
\]

where \( n \) is the outward unit normal to \( \Gamma \). We set

\[
0 = \langle \mathcal{L}'(u, w), (\hat{u}, \hat{w}) \rangle = \lim_{\varepsilon \to 0} \mathcal{L}((u, w) + \varepsilon(\hat{u}, \hat{w})) - \mathcal{L}(u, w)
\]

to obtain the equations of motion in weak form:

\[
\int_0^T \tilde{c}(\psi, \dot{\psi}, \dot{\psi}, \dot{v}, \dot{\varphi}) + (f_3, \dot{w})_\Omega
\]

\[
+ (M, \dot{\psi})_\Omega + (f, \dot{\psi})_\Omega + (m, \dot{\varphi})_\Gamma + (g, \dot{\varphi})_\Gamma + (g_3, \dot{w})_\Gamma dt = 0
\]

(3.4)

where \( \dot{\psi}, \dot{\varphi} \) and \( \varphi \) are given in terms of \( \{\hat{u}, \hat{w}\} \) by (3.1), (3.2) (but with hats on \( u, v, w, \varphi, \psi \)).

Define the forms \( a \) and \( c \) by

\[
a(u, w; \hat{u}, \hat{w}) = \tilde{a}(\psi, v, \varphi; \dot{\psi}, \dot{v}, \dot{\varphi}),
\]

(3.5)

\[
c(u, w; \hat{u}, \hat{w}) = \tilde{c}(\psi, v, \varphi; \dot{\psi}, \dot{v}, \dot{w}),
\]

(3.6)

where \( \{\psi, v, \varphi\} \) are related to \( \{u, w\} \) by (3.1), (3.2) and \( \{\dot{\psi}, \dot{v}, \dot{\varphi}\} \) are likewise related to \( \{\hat{u}, \hat{v}\} \).

From (2.13) \( p \) and \( q \) can be rewritten as

\[
\begin{cases}
    p = (S^+ - S^-)^T h^{-1} M + (S^+ + S^-)^T f / 2 \\
    q = (S^+ - S^-)^T h^{-1} m + (S^+ + S^-)^T g / 2.
\end{cases}
\]

(3.7)
In terms of the original variables $u, w$ and test functions in (3.3), it follows from (3.1), (3.7) that the equation of motion (3.4) may be rewritten

\[
\int_0^T c(\dot{u}, \dot{w}; \dot{u}, \dot{w}) - a(u, w; \dot{u}, \dot{w}) + (f_3, \dot{w})_\Omega + (p, \dot{u})_\Omega + (g_3, \dot{w})_{\Gamma_1} + (q, \dot{u})_{\Gamma_1} \, dt = 0.
\]  

(3.8)

3.3. Associated boundary value problem. The boundary value problem associated with (3.8) (or equivalently (3.4)) can be obtained through the usual integration by parts procedure.

Define for $i = 1, 2, \ldots, n$ and sufficiently smooth $\phi = \{\phi_1, \phi_2\}(x)$ the operators $\mathcal{M}^i[\phi]$ by

\[
\mathcal{M}^i[\phi] = D_i \begin{pmatrix}
\varepsilon_{11} + \nu_i \varepsilon_{22} & (1 - \nu_i) \varepsilon_{12} \\
(1 - \nu_i) \varepsilon_{12} & \nu_i \varepsilon_{11} + \varepsilon_{22}
\end{pmatrix}; 
\varepsilon_{jk}(\phi) = \frac{1}{2} \left( \frac{\partial \phi_j}{\partial x_k} + \frac{\partial \phi_k}{\partial x_j} \right).
\]

Thus $\mathcal{M}^i[\phi]$ is a symmetric matrix for every $x \in \Omega$.

We define the $\text{div}$ of a symmetric matrix to be the divergence of each row:

\[
\text{div} \begin{bmatrix}
a_{11} & a_{12} \\
a_{12} & a_{22}
\end{bmatrix} = \text{div}(a_{11}, a_{12}), \text{div}(a_{12}, a_{22})
\]

Then

\[
L^i \phi = \{L_1^i \phi, L_2^i \phi\} = \text{div} \mathcal{M}^i[\phi]
\]

defines a second-order operator which is given explicitly by

\[
L_j^i \phi = \frac{\partial}{\partial x_j} \left( D_i \frac{\partial \phi_j}{\partial x_j} \right) + \frac{\partial}{\partial x_k} \left( \frac{(1 - \nu_i)}{2} D_i \frac{\partial \phi_j}{\partial x_k} \right) + \frac{\partial}{\partial x_j} \left( \nu_i D_i \frac{\partial \phi_k}{\partial x_k} \right), \quad (j, k) = (1, 2), (2, 1).
\]

Let us also define the boundary operators $B^i \phi = \{B_1^i(\phi_1, \phi_2), B_2^i(\phi_1, \phi_2)\}$ by

\[
B^i \phi = \mathcal{M}^i[\phi] n,
\]

where $n = (n_1, n_2)$ denotes the outward unit normal to $\Gamma$. Explicitly, one has

\[
B_1^i(\phi_1, \phi_2) = D_i \begin{bmatrix}
\left( \frac{\partial \phi_1}{\partial x_1} n_1 + \nu_i \frac{\partial \phi_2}{\partial x_2} n_1 \right) + \left( \frac{1 - \nu_i}{2} \frac{\partial \phi_1}{\partial x_1} n_2 \right) & \left( \frac{1 - \nu_i}{2} \frac{\partial \phi_1}{\partial x_1} n_2 \right) + \left( \frac{\partial \phi_2}{\partial x_2} n_1 \right) \\
\left( \frac{\partial \phi_2}{\partial x_2} n_2 + \nu_i \frac{\partial \phi_1}{\partial x_1} n_2 \right) & \left( \frac{1 - \nu_i}{2} \frac{\partial \phi_2}{\partial x_2} n_2 \right) + \left( \frac{\partial \phi_1}{\partial x_1} n_1 \right)
\end{bmatrix},
\]

\[
B_2^i(\phi_1, \phi_2) = D_i \begin{bmatrix}
\left( \frac{\partial \phi_1}{\partial x_1} n_1 + \nu_i \frac{\partial \phi_2}{\partial x_2} n_1 \right) & \left( \frac{1 - \nu_i}{2} \frac{\partial \phi_1}{\partial x_1} n_2 \right) + \left( \frac{\partial \phi_2}{\partial x_2} n_1 \right) \\
\left( \frac{\partial \phi_2}{\partial x_2} n_2 + \nu_i \frac{\partial \phi_1}{\partial x_1} n_2 \right) & \left( \frac{1 - \nu_i}{2} \frac{\partial \phi_2}{\partial x_2} n_2 \right) + \left( \frac{\partial \phi_1}{\partial x_1} n_1 \right)
\end{bmatrix}.
\]

Assuming that the coefficients $D_i, \mu_i$, and $G_i (i = 1, \ldots, n)$ are smooth enough to allow integration by parts the following Green’s formula is valid for all sufficiently smooth $\hat{\phi}, \phi$:

\[
\hat{\phi}_i(\phi, \hat{\phi}) = (B^i \phi, \hat{\phi})_\Gamma - (L^i \phi, \hat{\phi})_{\Omega}. \quad (3.9)
\]

For $\xi = (\xi_j^i) (i = 1, 2, \ldots, n, j = 1, 2)$ define the matrices $L \xi$ and $B \xi$ by

\[
(L \xi)_{ij} = (L_j^i \xi^i), \quad (B \xi)_{ij} = (B_j^i \xi^i), \quad i = 1, 2, \ldots, n, \quad j = 1, 2.
\]
An integration by parts in $t$ of (3.4) followed by an application of (3.9) leads to the following:

$$0 = \int_{\Omega} \tilde{\omega} \left( (\mathbf{h} \cdot \rho)\tilde{\omega} - \text{div} \left( \sum_{i=1}^{n} G_{i} h_{i} \tilde{\psi}^{i} \right) - f_{3} \right) + \tilde{\psi} \cdot (\mathbf{h} \rho \tilde{\omega} - 12 \mathbf{h} L\psi - f) + \int_{\Gamma} \tilde{\psi} \cdot (-\mathbf{h}^{3} \mathcal{B} \psi + m) + \tilde{\omega} \left( \sum_{i=1}^{n} G_{i} h_{i} \tilde{\psi}^{i} \right) \cdot n - g_{3} \right)$$

$$+ \hat{\omega} \cdot (12 \mathbf{h} \mathcal{B} \psi - g)\, d\Gamma.$$ (3.10)

Next, one must choose an appropriate set of state variables. (Note: $\{\psi, v, w\}$ are not appropriate since they are not independent variables.) If we use $\{u, w\}$ we obtain the following:

\[
\begin{align*}
(i) \quad (p - h)w - \text{div}(\sum_{i=1}^{n} G_{i} h_{i} \varphi^{i}) &= f_{3}, \\
(ii) \quad (S^{+} - S^{-})^T[\rho \mathbf{h}^{2} \tilde{\psi}^{2}/12 + \mathbf{G} \varphi - \mathbf{h}^{2} L\psi] + \frac{1}{2} (S^{+} + S^{-})^T[\mathbf{h} \rho \tilde{\omega} - 12 \mathbf{h} L\psi] &= p \quad \text{in} \quad \Omega \times \mathbb{R}^+ \\
\end{align*}
\]

where $\psi, \varphi, \text{and } v$ are related to $u$ by (3.1), (3.2). The boundary conditions are

\[
\begin{align*}
(i) \quad w &= 0, \\
(ii) \quad v &= 0 \quad \text{on} \quad \Gamma_{0} \times \mathbb{R}^+, \\
\end{align*}
\]

(3.11)

\[
\begin{align*}
(i) \quad \sum_{k=i}^{n} (G_{i} h_{i} \varphi^{i}) \cdot n &= g_{3}, \\
(ii) \quad (S^{+} - S^{-})^T \mathbf{h}^{-1} \mathcal{B} \psi + 6(S^{+} + S^{-})^T \mathcal{B} v &= q \quad \text{on} \quad \Gamma_{1} \times \mathbb{R}^+. \\
\end{align*}
\]

(3.12)

Initial conditions can be given as

\[
\begin{align*}
(i) \quad w(x, 0) &= w^{0}(x), \quad \dot{w}(x, 0) = w^{1}(x) \\
(ii) \quad u(x, 0) &= u^{0}(x), \quad \dot{u}(x, 0) = u^{1}(x), \quad x \in \Omega, \\
\end{align*}
\]

(3.13)

for appropriate $u^{0}, u^{1}, w^{0}, w^{1}.$

3.4. Damped multilayer plates. Damping may be introduced into any of the plate layers by replacing the stress-strain relation (2.2) by an appropriate dissipative constitutive law. In the case of strain rate damping, the stresses depend not only on the strains, but also the strain rate and (2.4), (2.5) are modified to

\[
\begin{align*}
\sigma_{11} &= \frac{E + \tilde{E}}{1 - \nu^2} \left( \varepsilon_{11} + \nu \varepsilon_{22} \right), \quad \sigma_{12} = \frac{E + \tilde{E}}{1 + \nu} \varepsilon_{12}, \\
\sigma_{22} &= \frac{E + \tilde{E}}{1 - \nu^2} \left( \nu \varepsilon_{11} + \varepsilon_{22} \right), \quad \sigma_{13} = 2(G + \tilde{G} \frac{d}{dt}) \varepsilon_{13}, \\
\sigma_{33} &= 0, \quad \sigma_{23} = 2(G + \tilde{G} \frac{d}{dt}) \varepsilon_{23}, \\
\end{align*}
\]

where $\tilde{E}$ and $\tilde{G}$ may depend upon $x$ and $i$ and are assumed to be nonnegative.

By the correspondence principle, the equations of motion are given by simply replacing $E$ and $G$ by $E + \tilde{E} / dt$ and $G + \tilde{G} / dt$, respectively. The equation of motion (3.8) is
modified to

\[
\int_0^T \left[ c(\dot{u}, \dot{w}; \ddot{u}, \ddot{w}) - b(\dot{u}, \dot{w}; \ddot{u}, \ddot{w}) - a(u, w; \dot{u}, \dot{w}) + (f_3, \dot{w})_\Omega + (p, \dot{u})_\Omega + (g_3, \dot{w})_{\Gamma_1} + (q, \dot{u})_{\Gamma_1} \right] \, dt = 0,
\]

where the form \( b(\cdot; \cdot) \) is defined in an identical fashion to the way \( a(\cdot; \cdot) \) was defined, however, with \( E \) and \( G \) replaced by \( \tilde{E} \) and \( \tilde{G} \). (Of course, since \( D \) and \( G \) are defined in terms of \( E \) and \( G \), one also has to replace \( D \) and \( G \) by appropriate matrices, say \( \tilde{D} \) and \( \tilde{G} \), that are defined accordingly.)

From this correspondence it is simple to write down the boundary value problem analogous to (3.11)—(3.13) when strain rate damping is included. For example, the equations in (3.11) become

\[
\begin{align*}
(i) \quad & (\rho \cdot h)\ddot{w} - \text{div} \left( \sum_{i=1}^n G_i h_i \phi^i \right) - \text{div} \left( \sum_{i=1}^n \tilde{G}_i h_i \phi^i \right) = f_3, \\
(ii) \quad & \left( S^+ - S^- \right)^T \left[ \rho h^2 \phi^2 / 12 + G_\phi + \tilde{G}_\phi - h^2 L_\psi - h^2 \tilde{L}_\psi \right] \\
& + \frac{1}{2} \left( S^+ + S^- \right)^T \left[ h \rho \ddot{v} - 12 h L v - 12 h \tilde{L} \ddot{v} \right] = p, \quad \text{in } \Omega \times \mathbb{R}^+.
\end{align*}
\]

where \( \tilde{L} \) is defined in the same way as \( L \), but with \( \tilde{D} \) and \( \tilde{G} \) in place of \( D \) and \( G \). The boundary conditions in (3.13) are modified in the same way.

For a discussion of general viscoelastic damping within the Reissner-Mindlin framework we refer the reader to [6].

4. Existence, uniqueness, regularity. In this section we discuss existence, uniqueness, and regularity properties associated with solutions of the general damped (or undamped) plate equation (3.15).

Denote

\[ H_{1,0}^1 = \{ \phi : \phi \in H^1(\Omega), \phi = 0 \text{ on } \Gamma_0 \}. \]

In the case that \( \Gamma = \Gamma_0 \), \( H_{1,0}^1 = H_0^1(\Omega) \). Also define

\[ \mathcal{V} = (H_{1,0}^1)^{2n+3}, \quad \mathcal{H} = (L^2(\Omega))^{2n+3}. \]

The forms \( a(\cdot; \cdot) \) and \( c(\cdot; \cdot) \) defined in (3.5), (3.6) and the form \( b(\cdot; \cdot) \) in (3.15) are symmetric and bilinear. For convenience, denote by \( a(\cdot), b(\cdot), c(\cdot) \) the corresponding (nonnegative) quadratic functions, e.g., \( a(u, w) = a(u, w; u, w) \).

In all that follows we assume without further mention that the coefficients \( \rho_i, G_i, D_i, \nu_i \), etc. (\( i = 1, \ldots, n \)) are bounded and measurable on \( \Omega \).

4.1. Homogeneous boundary conditions. We first consider the problem (3.15) in the absence of boundary forces. In this case a variational formulation of (3.15) is: Find functions \{\( u, w \)\} such that

\[
\{ u, w \} \in C([0,T]; \mathcal{V}) \cap C^1([0,T]; \mathcal{H}),
\]

\[
\frac{d}{dt} [c(\dot{u}, \dot{w}; \ddot{u}, \ddot{w}) + b(\dot{u}, \dot{w}; \ddot{u}, \ddot{w})] + a(u, w; \dot{u}, \dot{w})
\]  
\[
(f_3, \dot{w})_\Omega + (p, \dot{u})_\Omega \quad \forall \{ \dot{u}, \dot{w} \} \in \mathcal{V}
\]  

(4.2)
in the sense of distributions on $(0, T)$, with
\[
\begin{align*}
\begin{cases}
\{u(0), w(0)\} = \{u^0, w^0\} & \text{given in } \mathcal{V}, \\
\{\dot{u}(0), \dot{w}(0)\} = \{u^1, w^1\} & \text{given in } \mathcal{H}.
\end{cases}
\end{align*}
\]
(4.3)

The forces $\{p, f_3\}$ are assumed to be in the class $L^2(0, T; \mathcal{H})$.

**Lemma 4.1.** The forms $a(\cdot; \cdot)$, $b(\cdot; \cdot)$, and $c(\cdot; \cdot)$ are continuous on $\mathcal{V} \times \mathcal{V}$, $\mathcal{V} \times \mathcal{V}$, and $\mathcal{H} \times \mathcal{H}$, respectively. Furthermore, there exist $\delta_a > 0$ and $\delta_c > 0$ for which
\[
\begin{align*}
|a(u, w)| & > \delta_a \|\{u, u\}\|_{\mathcal{V}}^2 \quad \forall \{u, w\} \in \mathcal{V}, \\
|b(u, w)| & > 0 \quad \forall \{u, w\} \in \mathcal{V}, \\
|c(u, w)| & > \delta_c \|\{u, w\}\|_{\mathcal{H}}^2 \quad \forall \{u, w\} \in \mathcal{H}.
\end{align*}
\]
(4.4)

*Proof.* A proof for the case $n = 1$ appears in [6, pp. 44–47] and the same idea remains valid here.

First note that $c(\cdot; \cdot)$ is continuous on $\mathcal{H} \times \mathcal{H}$ since it is a composition of continuous functions. Likewise, $a(\cdot; \cdot)$ and $b(\cdot; \cdot)$ are continuous on $\mathcal{V} \times \mathcal{V}$. Since $b(\cdot)$ is clearly nonnegative, (4.5) holds.

In the following $C_g$ represents a generic positive constant that may vary from line to line.

Let us prove (4.6). By the equivalence of finite-dimensional norms, for any $\{u, w\} \in \mathcal{H}$,
\[
c(u, w) = \tilde{c}(\psi, v, w)
\]
\[
\geq C_g \left[ (\psi, \psi)_\Omega + (v, v)_\Omega + (w, w)_\Omega \right]
\]
\[
= C_g \left[ (h^{-1}(S^+ - S^-)u, h^{-1}(S^+ - S^-)u)_\Omega \\
+ \frac{1}{4}((S^+ + S^-)u, (S^+ + S^-)u)_\Omega + (w, w)_\Omega \right]
\]
\[
\geq C_g \|((S^+ - S^-)u, (S^+ - S^-)u)_\Omega \\
+ ((S^+ + S^-)u, (S^+ + S^-)u)_\Omega + (w, w)_\Omega \|.
\]
(4.7)

Next note that
\[
|(S^+ - S^-)^T(S^+ - S^-) + (S^+ + S^-)^T(S^+ + S^-)|u, u)_\Omega \geq C_g \|u\|_\Omega^2
\]
since otherwise (being a sum of two nonnegative forms) $S^+ + S^-$ and $S^+ - S^-$ have a common null-vector. This would imply the existence of $u \neq 0$ such that $S^+u = S^-u = 0$ and this is impossible. Combining (4.7) and (4.8) gives (4.6).

Finally, we need to prove (4.4). It is shown in [6] that
\[
\tilde{a}_0^\Omega(\phi, \phi) \geq C_g \|\phi\|_{H_1(\Omega)}^2 \quad \forall \phi = \{\phi_1, \phi_2\} \in (H_1^2)'^2.
\]
(4.9)

(The proof of (4.9) involves the use of Poincaré’s inequality and Korn’s inequality.)

By virtue of (4.9) we have
\[
\tilde{a}_0^\Omega(\phi, \phi) \geq C_g \|\phi\|_{H_1(\Omega)}^2.
\]
Consequently, in the same way that (4.7) and (4.8) were obtained we have

\[
\tilde{a}_0(h\psi, \psi) + a_0(hv; v) \geq C_g(\|\psi\|_{H^1(\Omega)}^2 + \|v\|_{H^1(\Omega)}^2)^n + \|\psi\|_{H^1(\Omega)}^2 \geq C_g\|u\|_{H^1(\Omega)}^2 + 2.
\]

(4.10)

It follows from Poincaré's inequality that for any \( \alpha > 0 \) and any \( \{\phi, w\} \in (H^1_{10})^2 \times H^1_{10} \) that

\[
\|
phi\|^2_{(L^2(\Omega))^2} + \alpha(\nabla w + \phi, \nabla w + \phi)_{\Omega} \geq C_g\|
\phi, w\|_{H^1(\Omega)^3}^2
\]

(see [6, p. 44] for details). Consequently, for any \( \{\phi, w\} \in (H^1_{10})^{2n} \times H^1_{10} \) it follows that

\[
\|
\phi\|^2_{(L^2(\Omega))^{2n}} + \alpha(\nabla w + \phi, \nabla w + \phi)_{\Omega} \geq C_g\|
\phi, w\|_{H^1(\Omega)^{2n+1}}.
\]

(4.11)

Combining (4.10) with (4.11) (with \( \psi \) and \( v \) in place of \( \phi \)) we obtain (4.4).

With the coercive estimates in Lemma 4.1, it is rather standard to show that (4.1)–(4.3) is well-set. We briefly indicate the semigroup approach used in Lagnese [5, p. 29], to which the reader is referred for details.

We identify \( \mathcal{T} \) with its dual \( \mathcal{T}' \) and have the dense and continuous embeddings

\[
\mathcal{V} \subset \mathcal{H} = \mathcal{H}' \subset \mathcal{V}'.
\]

(4.12)

Let \( \langle \cdot, \cdot \rangle \) denote the duality pairing between \( \mathcal{V} \) and \( \mathcal{V}' \) that coincides with \( \langle \cdot, \cdot \rangle_{\mathcal{H}} \) when both arguments are in \( \mathcal{H} \). We may define (by Lemma 4.1) operators \( C \in \mathcal{L}(\mathcal{H}), B \in \mathcal{L}(\mathcal{V}, \mathcal{V}'), \) and \( A \in \mathcal{L}(\mathcal{V}, \mathcal{V}') \) by

\[
\langle Cu, v \rangle = c(u; v) \quad \forall u, v \in \mathcal{H},
\]

\[
\langle Bu, v \rangle = b(u; v) \quad \forall u, v \in \mathcal{V},
\]

\[
\langle Au, v \rangle = a(u; v) \quad \forall u, v \in \mathcal{V}.
\]

(4.13)

By Lemma 4.1, \( A \) and \( C \) are isomorphisms: \( \mathcal{V} \to \mathcal{V}' \) and \( \mathcal{H} \to \mathcal{H} \), respectively.

We set

\[
u = \{u, w\}, \quad f = \{p, f_3\}, \quad u^0 = \{u^0, w^0\}, \quad u^1 = \{u^1, w^1\}
\]

and rewrite (4.2)–(4.3) as

\[
C\ddot{u} + B\ddot{u} + Au = f \quad \text{in} \ \mathcal{V}', \quad u(0) = u^0, \quad \dot{u}(0) = u^1.
\]

(4.14)

In first-order form (4.12) becomes

\[
\frac{d}{dt}CU + AU = F, \quad U(0) = \{u^0, u^1\}^T,
\]

(4.15)

where

\[
A = \begin{pmatrix} 0 & -A \\ A & B \end{pmatrix}, \quad C = \begin{pmatrix} A & 0 \\ 0 & C \end{pmatrix}, \quad U = \begin{pmatrix} u \\ \dot{u} \end{pmatrix}, \quad F = \begin{pmatrix} 0 \\ f \end{pmatrix}.
\]

One can then verify that \( C^{-1}A \) is the generator of a strongly continuous contraction semigroup on (for example) \( \mathcal{V} \times \mathcal{H} \). Since solutions in \( \mathcal{V} \times \mathcal{H} \) can be shown to correspond to variational solutions of (4.1)–(4.3) we have the following result.
Proposition 4.2. There is a unique solution \( \{u, w\} \) to (4.1)-(4.3). Moreover, the mapping \( \{\{u^0, w^0\}, \{u^1, w^1\}, \{p, f_3\}\} \rightarrow \{\{u, w\}, \{\dot{u}, \dot{w}\}\} \) is a continuous mapping of
\[
\mathcal{V} \times \mathcal{H} \times L^2(0, T; \mathcal{H}) \rightarrow C([0, T]; \mathcal{V} \times \mathcal{H}).
\]

Remark 4.3. Weaker classes of solutions may also be defined by extension of the relevant semigroup. In particular, define \( \mathcal{Z} \) to be the completion of \( \mathcal{V} \times \mathcal{H} \) with respect to the norm
\[
\|\{u, v\}\|_{\mathcal{Z}} = \|A^{-1}C\{u, v\}\|_{\mathcal{V} \times \mathcal{H}}.
\]
It follows that
\[
\mathcal{Z} = \{\{u, v\} \in \mathcal{H} \times (\mathcal{V}' + B\mathcal{H}) : Bu + v \in \mathcal{V}'\}.
\]
It is easily verified that the semigroup generated by \( C^{-1}A \) (used in Proposition 4.2) extends continuously to the space \( \mathcal{Z} \) and hence given any \( \{u^0, u^1\} \in \mathcal{Z} \) and any \( \mathbf{F} \in L^2(0, T; \mathcal{Z}) \) there is a unique solution \( \mathbf{U} \) of (4.13) for which \( \mathbf{U} \in C([0, T]; \mathcal{Z}) \).

4.2. Nonhomogeneous boundary data. The presence of the boundary forces \( g_3 \) and \( q \) in (3.15) makes it impossible to directly define solutions by the variational approach. Instead, one must initially define a weaker notion of solution. In applying the method of transposition (see [7]), solutions are defined by duality with respect to solutions of an adjoint problem. This method is applied in the case of a single-layer Reissner-Mindlin plate in [6, pp. 64, 65] and the same approach is valid here. Therefore, we simply state the result [6, Theorem 3.3, p. 65] as it applies to our problem.

Proposition 4.4. Assume \( \{\{u^0, w^0\}, \{u^1, w^1\}\} \in \mathcal{Z}, \{p, f_3\} \in L^2(0, T; \mathcal{V}') \) and \( \{q, g_3\} \in L^2(0, T; (H^{1/2}(\Gamma_1))^{2n+3})' \). Then there exists a unique solution (in the sense of transposition) \( \{u, w\} \) to (3.15) with
\[
\{\{u, w\}, \{\dot{u}, \dot{w}\}\} \in C([0, T]; \mathcal{Z}).
\]
Moreover, the mapping of
\[
\{\{u^0, w^0\}, \{u^1, w^1\}\}, \{p, f_3\}, \{q, g_3\}\} \rightarrow \{\{u, w\}, \{\dot{u}, \dot{w}\}\}
\]
is a continuous mapping of
\[
\mathcal{Z} \times L^2(0, T; \mathcal{V}') \times L^2(0, T; (H^{1/2}(\Gamma_1))^{2n+3})' \rightarrow C([0, T]; \mathcal{Z}).
\]

5. Symmetric case. In this section we examine the special case where the thicknesses, densities, and elastic parameters are symmetric with respect to the center layer (if \( n \) is odd) or the center interface (if \( n \) is even). We show that the equations of motion decouple into a bending part and a stretching part; that is, a part involving the transverse displacement and another part completely independent of the transverse displacement. Solutions of the bending equations turn out to have antisymmetric displacements with respect to the center of the plate, while those of the stretching part have symmetric displacements.
5.1. **Symmetry properties.** Let $R$ denote the matrix that reverses the coordinates in $\mathbb{R}^m$ ($m$ arbitrary):

$$R\{\phi_1, \phi_2, \ldots, \phi_m\}^T = \{\phi_m, \phi_{m-1}, \ldots, \phi_1\}^T.$$ 

For any vector $\phi$ in $\mathbb{R}^m$ define the symmetric part $\phi_s$ and antisymmetric part $\phi_a$ by

$$\phi_s = \frac{\phi + R\phi}{2}, \quad \phi_a = \frac{\phi - R\phi}{2}. \quad (5.1)$$

Thus by (5.1) every vector $\phi$ has the orthogonal decomposition

$$\phi = \phi_s + \phi_a, \quad \phi_s \cdot \phi_a = 0. \quad (5.2)$$

In this section we assume that all physical parameters ($E, G, \nu$, thicknesses, densities, etc.) are symmetric with respect to the layers. If $\Lambda$ denotes any of the matrices $\rho, h, D, \tilde{D}, G, \tilde{G}, \text{diag}(\nu_1, \ldots, \nu_n)$ then it is easy to check that

$$R\Lambda = \Lambda R. \quad (5.3)$$

Recall the general variational problem: Find functions $\{u, w\}$ that satisfy

$$\{u, w\} \in C([0, T]; \mathcal{V}) \cap C^1([0, T]; \mathcal{H}), \quad (5.4)$$

$$\frac{d}{dt} [c(\dot{u}, \dot{w}) + b(u, w; \dot{u}, \dot{w})] + a(u, w; \dot{u}, \dot{w})$$

$$= (f_3, w)_\Omega + (p, \dot{u})_\Omega + (q, \dot{u})_{\Gamma_1} + (g_3, \dot{w})_{\Gamma_1} \quad \forall \{\dot{u}, \dot{w}\} \in \mathcal{V},$$

$$\{u(0), w(0)\} = \{u^0, w^0\}, \quad \{\dot{u}(0), \dot{w}(0)\} = \{\dot{u}^1, \dot{w}^1\}. \quad (5.5)$$

**Theorem 5.1.** Suppose the thicknesses, densities, and elastic parameters are symmetric with respect to the center of the plate, i.e., (5.3) holds. Then every solution $\{u, w\}$ of (5.4)–(5.6) can be decomposed as

$$\{u, w\} = \{u_a, w\} + \{u_s, 0\}, \quad (5.7)$$

where $\{u_a, w\}$ satisfies (5.4) and is a solution of

$$\frac{d}{dt} [c(\dot{u}_a, \dot{w}) + b(u_a, w; \dot{u}, \dot{w})] + a(u_a, w; \dot{u}, \dot{w})$$

$$= (f_3, \dot{w})_\Omega + (p_a, \dot{u})_\Omega + (q_a, \dot{u})_{\Gamma_1} + (g_3, \dot{w})_{\Gamma_1} \quad \forall \{\dot{u}, \dot{w}\} \in \mathcal{V},$$

$$\{u_a(0), w(0)\} = \{u^0_a, w^0\}, \quad \{\dot{u}_a(0), \dot{w}(0)\} = \{\dot{u}^1_a, \dot{w}^1\}, \quad (5.8)$$

and $\{u_s, 0\}$ satisfies (5.4) and is a solution of

$$\frac{d}{dt} [c(\dot{u}_s, 0; \dot{u}, \dot{w}) + b(u_s, 0; \dot{u}, \dot{w})] + a(u_s, 0; \dot{u}, \dot{w})$$

$$= (p_s, \dot{u})_\Omega + (q_s, \dot{u})_{\Gamma_1} \quad \forall \{\dot{u}, \dot{w}\} \in \mathcal{V},$$

$$u_s(0) = u^0_s, \quad \dot{u}_s(0) = \dot{u}^1_s. \quad (5.9)$$

**Remark 5.2.** The proof is completely algebraic and hence the same result holds for weaker classes of solutions (in particular, those given in Proposition 4.4).
Proof. The continuity of \( \{u_a, w\} \) and \( \{u_s, 0\} \) is the same as \( \{u, w\} \). Furthermore, (5.9) and (5.11) follow immediately from (5.2). The main point is to verify the invariance in (5.8) and (5.10).

Suppose we prove that for any \( \{u, w\} \in \mathcal{V} \times \mathcal{H} \) and any \( \{\hat{u}, \hat{w}\} \in \mathcal{V} \times \mathcal{H} \)

\[
a(u_a, w; \hat{u}_s, 0) = b(u_a, w; \hat{u}_s, 0) = c(u_a, w; \hat{u}_s, 0) = 0.
\]

(5.12)

It then would follow that

\[
a(u, w; \hat{u}, \hat{w}) = a(u_a, w; \hat{u}_a, \hat{w}) + a(u_s, 0; \hat{u}_s, 0),
\]

\[
b(u, w; \hat{u}, \hat{w}) = b(u_a, w; \hat{u}_a, \hat{w}) + b(u_s, 0; \hat{u}_s, 0),
\]

\[
c(u, w; \hat{u}, \hat{w}) = c(u_a, w; \hat{u}_a, \hat{w}) + c(u_s, 0; \hat{u}_s, 0).
\]

Then, for example, (5.8) would be the same as

\[
\frac{d}{dt} [c(\dot{u}_a, \dot{w}; \hat{u}_a, \hat{w}) + b(u_a, w; \dot{u}_a, \hat{w})] + a(u_a, w; \dot{u}_a, \hat{w})
\]

\[
= (f_3, \hat{w})_\Omega + (p_a, \hat{u}_a)_\Omega + (q_a, \hat{u}_a)_\Gamma_1 + (g_3, \hat{w})_\Gamma_1, \quad \forall \{\hat{u}, \hat{w}\} \in \mathcal{V},
\]

which is precisely the equation obtained from (5.5) with \( \hat{u}_s = 0 \).

Therefore, it will suffice to prove (5.12).

Let \( \varphi, \psi, \) and \( v \) be defined by \( u, w \) by (3.1), (3.2) and assume \( \hat{\varphi}, \hat{\psi}, \hat{v} \) are likewise defined in terms of \( \dot{u}, \dot{w} \).

Let \( S^+ \) and \( S^- \) denote the matrices in (3.1). One can easily verify the following:

\[
RS^+\varphi = S^-R\varphi, \quad RS^-\varphi = S^+R\varphi, \quad \forall \varphi \in \mathbb{R}^n.
\]

(5.13)

Of course the matrices \( R \) appearing on each side of the equations in (5.13) are not the same since their dimensions are different.

The following are easily obtained using (5.13):

\[
\psi_s = h^{-1}(S^+ - S^-)u_a, \quad \psi_a = h^{-1}(S^+ - S^-)u_s,
\]

(5.14)

\[
v_s = (S^+ + S^-)u_s/2, \quad v_a = (S^+ + S^-)u_a/2,
\]

(5.15)

\[
\varphi_s = \vec{\nabla}w + \psi_s, \quad \varphi_a = \psi_a.
\]

(5.16)

For example, to obtain the first identity in (5.14), we use (5.3) (applied to \( h^{-1} \)) and (5.13) to obtain

\[
\psi_s = (h^{-1}(S^+ - S^-)u + Rh^{-1}(S^+ - S^-)u)/2
\]

\[
= (h^{-1}(S^+ - S^-)u + h^{-1}(S^- - S^+)Ru)/2
\]

\[
= h^{-1}S^+(u - Ru)/2 - h^{-1}S^-(u - Ru)/2 = h^{-1}(S^+ - S^-)u_a.
\]

Equation (5.16) follows from (5.14) and the fact that \( R\vec{\nabla}w = \vec{\nabla}w \).
Now we can easily verify (5.12). For example,
\[
c(u_a, w; \hat{u}_s, 0) = c(\psi_s, v_a, w; \hat{\psi}_a, \hat{v}_s, 0) \\
= \rho h^3 \psi_s \cdot \dot{\psi}_a + \rho h v_a \cdot \dot{v}_s \\
= R \rho h^3 \psi_s \cdot R \dot{\psi}_a + R \rho h v_a \cdot R \dot{v}_s \\
= \rho h^3 \psi_s \cdot (-1)^{\text{top}} \dot{\psi}_a + \rho h (-1)^{\text{top}} v_a \cdot \dot{v}_s \\
= -c(u_a, w; \hat{u}_s, 0);
\]
thus, the last equality in (5.12) holds. The first two are proved in exactly the same way. □

5.2. Bending equations for symmetrically layered plates. It follows from the invariance of the antisymmetric solutions that the boundary value problem for the bending component of the motion is given by the same system (3.11)—(3.14), with the forces and initial data replaced by their antisymmetric components, as in Theorem 5.1. However, the resulting equations are not independent due to the antisymmetry property of the solution. Roughly speaking, a minimal set of equations is given by the equations for the transverse displacement $w$ together with the equations for the in-plane displacements of the “top half” of the plate.

Let us make this precise. Since the solutions are antisymmetric about the center of the plate, the solution obtained for $n$ even is identical to the solution obtained for $n$ odd, once the center two layers are identified as a single layer. Thus, we only need to consider the case where $n$ is even:

\[ n = 2m. \]

Therefore, assume that the layers of the plate are indexed $i = \pm 1, \pm 2, \ldots, \pm m$, and the surfaces are indexed $i = -m, \ldots, 0, \ldots, m$. Then by antisymmetry, $u_a^0 = 0$. Hence there are $2n + 1$ equations: one for the transverse displacement and $2n$ for $u_a$.

Since $u_a^0 = 0$ the $n$ equations for the upper half of the plate (those with $i > 0$) are decoupled from the $n$ equations for the lower layers. Furthermore, it is easily checked that the equations for the upper half are identical to the equations for the lower half, with the exception that the initial data and applied forces are opposite in sign. The boundary value problem for the upper half of the plate (without damping) then consists of (i) of (3.11)—(3.14) together with the first $n$ equations (those involving only $i > 0$) in (ii) of (3.11)—(3.14). The in-plane displacements for the lower half of the plate are then determined by antisymmetry. The equations in the damped case are obtained in the same way.

As an example, let us write out the bending equations for a symmetric three-layered plate. Since the parameters $\rho, h, G, D$ are symmetric, let us denote

\[
\rho = \text{diag}(\rho_1, \rho_0, \rho_1), \quad h = \text{diag}(h_1, h_0, h_1), \quad \text{etc.}
\]
Likewise, the variables $\psi$ and $\varphi = \nabla w + \psi$ are symmetric while the variables $v$ and $u$ are antisymmetric:

$$
\psi = \begin{pmatrix} \psi^1 \\ \psi^0 \end{pmatrix}, \quad \varphi = \begin{pmatrix} \varphi^1 \\ \varphi^0 \end{pmatrix}, \quad v = \begin{pmatrix} v^1 \\ 0 \end{pmatrix}, \quad u = \begin{pmatrix} u^1 \\ -u^0 \end{pmatrix}.
$$

Since the external force $p$ is also antisymmetric, assume $p$ is indexed in the same way $u$ is. For $\phi = \{\phi_1, \phi_2\}$ let us define

$$
\Box^i \phi = \frac{\rho_i h_i^2}{12} \phi - h_i^2 L^i \phi.
$$

Then (3.11) becomes

(i) $$(2\rho_1 h_1 + \rho_0 h_0) \dot{w} - \text{div}(2G_1 h_1 \varphi^1 + G_0 h_0 \varphi^0) = f_3,$$

(ii) $$
\begin{align*}
\Box^1 \psi^1 + G_1 \varphi^1 + \frac{6}{h_1} \Box^1 u^1 &= p^1, \\
\Box^0 \psi^0 - \Box^1 \psi^1 + G_0 \varphi^0 - G_1 \varphi^1 + \frac{6}{h_1} \Box^1 u^1 &= p^0,
\end{align*}
$$

which hold on $\Omega \times \mathbb{R}^+$. Recalling from (5.14)-(5.16) that

$$
\psi^1 = \frac{u^1 - u^0}{h_1}, \quad \psi^0 = \frac{2u^0}{h_0}, \quad v^1 = -\frac{u^1 + u^0}{2},
$$

(ii) of (5.18) can be written in terms of $u$ as

$$
\begin{align*}
\frac{1}{h_1} \Box^1 (4u^1 + 2u^0) + G_1 \varphi^1 &= p^1, \\
\frac{1}{h_0} \Box^0 (2u^0) + \frac{1}{h_1} \Box^1 (2u^1 + 4u^0) + G_0 (2u^0/h_0 + \nabla w) - G_1 \varphi^1 &= p^0,
\end{align*}
$$

If we use $\psi = \psi^1$ and $s = u^0/(2h_1)$ for state variables the system (5.18) can be written as

(i) $$(2\rho_1 h_1 + \rho_0 h_0) \dot{w} - \text{div}(2G_1 h_1 \varphi^1 + G_0 h_0 \nabla w + 4h_1 G_0 s) = f_3,$$

(ii) $$8h_1 \Box^1 (\psi + 3s) + (2h_1 G_1) \varphi^1 = 2h_1 p^1,$$

(iii) $$8h_1 \Box^1 s + \frac{4}{3} \frac{(2h_1)^2}{h_0} (\Box^0 s + G_0 s) + \frac{4}{3} h_1 G_0 \nabla w - G_1 \varphi^1 = \widetilde{M},$$

where

$$
\varphi^1 = \psi + \nabla w, \quad \widetilde{M} = \frac{2h_1}{3} (2p^0 - p^1).
$$

Let us make a couple of purely formal observations (which can be made precise). As $h_0 \to 0$ we expect to recover the usual Reissner-Mindlin plate (i.e., the bending component of (3.11) with $n = 1$; see also [6, p. 13]) since in the limit we are left with a symmetric two-layered plate, and as we have mentioned, this is the same as a one-layered plate once the two layers are identified as a single layer. Indeed, multiplying (iii) of (5.19) through by $h_0$ then formally setting $h_0$ to zero results in

$$
\Box^0 s + G_0 s = 0.
$$
If $s$ and $\dot{s}$ are initially zero, and appropriate homogeneous boundary conditions are specified, then the unique solution of (5.20) is $s = 0$, as one would expect as $h_0 \to 0$. Next we set $s = 0$ and $h_0 = 0$ in (i) and (ii), and replace $2h_1$ by $h$ to obtain

\begin{align*}
(\text{i}) \quad & \rho_1 h \ddot{w} - \text{div}(G_1 h \varphi^1) = f_3, \\
(\text{ii}) \quad & \frac{\rho_1 h^3}{12} \dddot{\psi} - h^3 L^1 \psi + G_1 h \varphi^1 = h p^1,
\end{align*}

where

$$\varphi^1 = \psi + \nabla w,$$

which are precisely the Reissner-Mindlin equations for a single plate of thickness $h$, modulus of flexural rigidity $h^3 D_1$, modulus of shear $h G_1$, and density $\rho_1$.

We can also relate (5.19) to the plate model developed in Hansen [2], which describes a two-layer plate with interfacial slip. In this model, $h_0$ and $G_0$ are both assumed to be very small compared to $h$ and $G_1$. Thus in (5.19) we pass the limits $h \to 0$ and $G_0 \to 0$ with $\gamma = \frac{G_0}{h_0}$ fixed. We obtain

\begin{align*}
(\text{i}) \quad & \rho_1 \dot{h} \ddot{w} - \text{div}(G_1 h \varphi^1) = f_3, \\
(\text{ii}) \quad & \frac{\rho_1 h^3}{12} (\dddot{\psi} + 3\dddot{s}) - h^3 L^1 (\psi + 3s) + h G_1 \phi^1 = h p^1, \\
(\text{iii}) \quad & \frac{\rho_1 h^3}{12} \dddot{s} - h^3 L^1 s + \frac{4}{3} \gamma h^2 s - G_1 \varphi^1 = \frac{h}{3} (2p^0 - p^1),
\end{align*}

where

$$\varphi^1 = \psi + \nabla w,$$

which is precisely the system developed in [2].

5.3. Stretching equations of symmetrically layered plates. Likewise it follows from the invariance of the symmetric solutions that the boundary value problem for the stretching component of the motion (the part independent of $w$) is given by the same system as for the general $n$-layer problem, when one replaces the forces and initial data by their symmetric components, as in Theorem 5.1.

Thus the boundary value problem (in the undamped case) is then the same as (3.11)–(3.14) but with the forces and initial data replaced by their antisymmetric components and with $0, \psi_\alpha, v_\alpha, \psi_\alpha$ in place of $w, \psi, v, \varphi$, respectively.

The equations for the stretching component of the “upper half” of the plate again form an independent set of equations. To be more precise, assume for definiteness that $n$ is even and the layers are indexed as in Sec. 5.2. Then the equations in (3.11)–(3.14) with $i > 0$ are identical to those with $i < 0$. Hence an independent set of equations for the middle interface and upper layers is given by those equations in (ii) of (3.11)–(3.14) with $i \geq 0$.

As an example, let us write out the stretching equations for a symmetric three-layered plate.

As in the example for the bending equations, we may assume that $\rho, D, G, h$ are given by (5.17). This time $\psi$ is an antisymmetric variable while $v, u, \text{ and } p$ are symmetric.
Thus we set
\[
\psi = \begin{pmatrix} \psi^1 \\ 0 \\ -\psi^1 \end{pmatrix}, \quad v = \begin{pmatrix} v^1 \\ v^0 \\ v^1 \end{pmatrix}, \quad u = \begin{pmatrix} u^1 \\ u^0 \\ u^1 \end{pmatrix}, \quad p = \begin{pmatrix} p^1 \\ p^0 \\ p^1 \end{pmatrix}.
\]

Proceeding as discussed above, the stretching motions of (3.11) are
\[
\square^1 \psi^1 + G_1 \psi^1 + \frac{6}{h_1} \square^1 v^1 = p^1, \\
\left( \frac{6}{h_0} \square^0 v^0 + \frac{6}{h_1} \square^1 v^1 - \square^1 \psi^1 - G^1 \psi^1 \right) = p^0,
\]
which hold on \( \Omega \times \mathbb{R}^+ \). From (5.14)-(5.16) we have
\[
v^0 = u^0, \quad v^1 = \frac{u^1 + u^0}{2}, \quad \psi^1 = \frac{u^1 - u^0}{h_1}.
\]
Thus in terms of \( u \) (5.21) can be rewritten
\[
\left( \frac{6}{h_0} \square^0 + \frac{6}{h_1} \square^1 \right) u^0 + \frac{6}{h_1} \square^1 u^1 = p^0 + p^1, \\
- \left( \frac{\square^1}{h_1} + \frac{3}{h_0} \square^0 + \frac{G_1}{h_1} \right) u^0 + \frac{1}{h_1} (\square^1 + G_1) u^1 = (p_0 - p_1)/2.
\]
As \( h_0 \to 0 \), one sees (at least formally) that \( \square^0/h_0 \to 0 \), so that in the limit one expects to obtain
\[
\frac{6}{h_1} \square^1 (u^0 + u^1) = p^0 + p^1, \\
\left( \frac{\square^1}{h_1} + \frac{G_1}{h_1} \right) (u^1 - u^0) = (p_0 - p_1)/2.
\]

The above are (as one would expect) the same equations we would have obtained assuming there were two symmetric layers instead of three. (To compare the equations, \( p_0 \) in (5.22) should be divided by two in order to have the same meaning as \( p_0 \) for the case \( n = 2 \).) Note that the two equations in (5.22) are completely decoupled. This is due to the fact that the wave speeds in each layer are the same and will not occur in general for \( n \geq 3 \). It is also worth noting that by letting \( h = 2h_1 \) and choosing \( v^1 \) for the state variable, the top equation of (5.22) takes the form
\[
\rho_1 h \ddot{v}^1 - 12hL^i v^1 = 2(p^0 + p^1),
\]
which, when the forces \( 2(p^0 + p^1) \) are interpreted as the resultant in-plane force, is the usual equation for plane elasticity (see also [6, p. 17]).

\[1\] A factor of \( h \) is missing next to \( E \) in [6, (4.1), p. 17].
