AND

LAURENT YOUNES (Center for Imaging Science, The Johns Hopkins University, 3400 N-Charles Street, Baltimore, Maryland 21218-2686)

Abstract. In the pattern matching approach to imaging science, the process of “metamorphosis” is template matching with dynamical templates (Trouvé and Younes, Found. Comp. Math., 2005). Here, we recast the metamorphosis equations of that paper into the Euler-Poincaré variational framework of Holm, Marsden, and Ratiu, Adv. in Math., 1998 and show that the metamorphosis equations contain the equations for a perfect complex fluid (Holm, Springer, 2002). This result connects the ideas underlying the process of metamorphosis in image matching to the physical concept of an order parameter in the theory of complex fluids. After developing the general theory, we reinterpret various examples, including point set, image and density metamorphosis. We finally discuss the issue of matching measures with metamorphosis, for which we provide existence theorems for the initial and boundary value problems.

1. Overview. Pattern matching is an important component of imaging science, with privileged applications in computerized anatomical analysis of medical images (computational anatomy) [2, 4, 12, 23]. When comparing images, the purpose is to find, based on the conservation of photometric cues, an optimal nonrigid alignment between the images.
In this context, diffeomorphic pattern matching methods have been developed, based on this principle, and on the additional goal of defining a (Riemannian) metric structure on spaces of deformable objects \[7, 24\]. They have found multiple applications in medical imaging \[16, 3, 11, 30, 10, 29\], where the objects of interest include images, landmarks, measures (modeling unlabeled point sets) and currents (modeling curves and surfaces). These methods address the registration problem by solving a variational problem of the form

\[
\text{Find } \arg \min \left( d(\text{id}, g)^2 + \text{Errorterm}(g, n_{\text{temp}}, n_{\text{targ}}) \right)
\]

over all diffeomorphisms \( g \), where \( n_{\text{temp}} \) and \( n_{\text{targ}} \) are the compared objects (usually referred to as the template and the target), \( (g, n) \mapsto g.n \) is the action of diffeomorphisms on the objects and \( d \) is a right-invariant Riemannian distance on diffeomorphisms. This problem therefore directly relates to geodesics in groups of diffeomorphisms, namely to the EPDiff equation \[1, 18, 14\], and the conserved initial momentum that specifies the solution has been used in statistical studies in order to provide anatomical characterizations of mental disorders \[22, 31\].

One of the issues in problems formulated as (1) is that the error term breaks the metric aspects inherited from the distance \( d \) on diffeomorphisms. This model has an inherent template vs. target asymmetry, which is not always justified. With the purpose of designing a fully metric approach to the template matching problem, Metamorphoses have been introduced in \[20\], and formalized and studied in \[28, 27\]. They provide interesting pattern matching alternatives to (1), in a completely metric framework. In this paper, we pursue the following twofold goal: (i) provide a generic Lagrangian formulation for metamorphoses that includes the Riemannian formalism introduced in \[28\], and (ii) study a new form of metamorphoses, adapted to the deformation of measures.

We start with (i), for which our point of view will be fairly abstract. We consider a manifold, \( N \), which is acted upon by a Lie group \( G \): \( N \) contains what we can refer to as “deformable objects” and \( G \) is the group of deformations, which is the group of diffeomorphisms in our applications. We will review several examples for the space \( N \) later on in this paper.

**Definition 1.** A **metamorphosis** \[28\] is a pair of curves \((g_t, \eta_t) \in G \times N\) parameterized by time \( t \), with \( g_0 = \text{id} \). Its **image** is the curve \( n_t \in N \) defined by the action \( n_t = g_t.\eta_t \). The quantities \( g_t \) and \( \eta_t \) are called the **deformation part** of the metamorphosis, and its **template part**, respectively. When \( \eta_t \) is constant, the metamorphosis is said to be a **pure deformation**. In the general case, the image is a combination of a deformation and template variation.

In \[28\], metamorphoses were used to modify an original Riemannian metric on \( N \) by including a deformation component in the geodesic evolution. In this paper, we generalize the approach to a generic Lagrangian formulation, and apply the Euler-Poincaré variational framework \[14\] to derive evolution equations. More specific statements on these equations (for example, regarding the existence and uniqueness of solutions) require additional assumptions on \( G \) and the space \( N \) of deformed objects. In the second part of this paper, we will review the case in which \( N \) is a space of linear forms on a
Hilbert space of smooth functions, which will allow us to define metamorphoses between measures.

The next section provides the notation and definitions related to the general problem of metamorphoses.

2. Notation and Lagrangian formulation. We will use either letters \( \eta \) or \( n \) to denote elements of \( N \), the former being associated to the template part of a metamorphosis, and the latter to its image.

The variational problem we shall study optimizes over metamorphoses \((g_t, \eta_t)\) by minimizing, for some Lagrangian \( L \),

\[
\int_0^1 L(g_t, \dot{g}_t, \eta_t, \dot{\eta}_t) dt
\]

with fixed boundary conditions for the initial and final images \( n_0 \) and \( n_1 \) (with \( n_t = g_t \eta_t \)) and \( g_0 = \text{id}_G \) (so only the images are constrained at the end-points, with the additional normalization \( g_0 = \text{id} \)).

Let \( g \) denote the Lie algebra of \( G \). We will consider Lagrangians defined on \( TG \times TN \) that satisfy the following invariance condition: there exists a function \( \ell \) defined on \( g \times TN \) such that

\[
L(g, U_g, \eta, \xi) = \ell(U_g g^{-1}, g \eta, g \xi, \eta).
\]

In other terms, \( L \) is invariant by the right action of \( G \) on \( G \times N \) defined by \( (g, \eta) h = (gh, h^{-1} \eta) \).

For a metamorphosis \((g_t, \eta_t)\), we therefore have, letting \( u_t = \dot{g}_t g_t^{-1}, n_t = g_t \eta_t \) and \( \nu_t = g_t \dot{\eta}_t \),

\[
L(g_t, \dot{g}_t, \eta_t, \dot{\eta}_t) = \ell(u_t, n_t, \nu_t).
\]

The Lie derivative with respect to a vector field \( X \) will be denoted \( \mathcal{L}_X \). The Lie algebra of \( G \) is identified with the set of right invariant vector fields \( U_g = u g, u \in T_{\text{id}} G = g \), \( g \in G \), and we will use the notation \( \mathcal{L}_u = \mathcal{L}_U \).

The Lie bracket \([u, v]\) on \( g \) is defined by

\[
\mathcal{L}_{[u, v]} = - (\mathcal{L}_u \mathcal{L}_v - \mathcal{L}_v \mathcal{L}_u)
\]

and the associated adjoint operator is \( \text{ad}_u v = [u, v] \). Letting \( I_g(h) = ghg^{-1} \) and \( \text{Ad}_v g = \mathcal{L}_v I_g(\text{id}) \), we also have \( \text{ad}_u v = \mathcal{L}_u (\text{Ad}_u)(\text{id}) \). When \( G \) is a group of diffeomorphisms, this yields \( \text{ad}_u v = Du v - Du u \).

The pairing between a linear form \( \ell \) and a vector \( u \) will be denoted \((\ell | u)\). Duality with respect to this pairing will be denoted with a \( * \) exponent.

When \( G \) acts on a manifold \( \tilde{N} \), the \( \diamond \) operator is defined on \( T \tilde{N}^* \times \tilde{N} \) and takes values in \( g^* \). It is defined by

\[
(\delta \diamond \tilde{n} | u) = - (\delta | u \tilde{n}).
\]
3. Euler equations. We compute the Euler equations associated with the minimization of
\[ \int_0^1 \ell(u_t, n_t, \nu_t) dt \]
with fixed boundary conditions \( n_0 \) and \( n_1 \). We therefore consider variations \( \delta u \) and \( \omega = \delta n \). The variation \( \delta \nu \) can be obtained from \( n = g\eta \) and \( \nu = g\eta \) yielding \( \dot{n} = \nu + un \) and \( \dot{\omega} = \delta \nu + u\omega + \delta un \). Here and in the remainder of this paper, we assume that computations are performed in a local chart on \( TN \) with respect to which we take partial derivatives.

We therefore have
\[ \int_0^1 \left( \left( \frac{\delta \ell}{\delta u} \right) \delta u_t + \left( \frac{\delta \ell}{\delta n} \right) \omega_t + \left( \frac{\delta \ell}{\delta \nu} \right) \dot{\omega}_t - u_t \omega_t - \delta u_t n_t \right) dt = 0. \]
The \( \delta u \) term yields the equation
\[ \frac{\partial \ell}{\partial u} + \frac{\partial \ell}{\partial \nu} \circ n_t = 0. \]
(Note the abuse of notation: \( \delta \ell/\delta \nu \in T(TN)^* \) is considered as a linear form on \( TN \) by \( (\delta \ell/\delta \nu) z := (\delta \ell/\delta \nu)(0, z) \).) For the \( \omega \) term, we get, after an integration by parts,
\[ \frac{\partial \delta \ell}{\partial t \delta \nu} + u_t \star \frac{\delta \ell}{\delta \nu} - \frac{\delta \ell}{\delta n} = 0, \]
where we have used the notation
\[ \left( \frac{\delta \ell}{\delta \nu} \right) u\omega = (u \star \frac{\partial \ell}{\partial \nu}) \omega. \quad (3) \]
We therefore obtain the system of equations
\[ \begin{cases} \frac{\delta \ell}{\delta u} + \frac{\partial \ell}{\partial \nu} \circ n_t = 0, \\ \frac{\partial \delta \ell}{\partial t \delta \nu} + u_t \star \frac{\delta \ell}{\delta \nu} = \frac{\delta \ell}{\delta n}, \\ \dot{n}_t = \nu_t + u_t n_t. \end{cases} \quad (4) \]
Note that \( \frac{\partial \ell}{\partial u} + \frac{\partial \ell}{\partial \nu} \circ n \) is the momentum arising from Noether’s theorem for the invariance of the Lagrangian being considered. The special form of the boundary conditions (fixed \( n_0 \) and \( n_1 \)) ensures that this momentum is zero.

4. Euler-Poincaré reduction. An equivalent system can be obtained via an Euler-Poincaré reduction [14]. In this setting, we make the variation in the group element and in the template instead of the velocity and the image. We let \( \xi_t = \delta g_t g_t^{-1} \) and \( \varpi_t = g_t \delta \eta_t \). From this, we obtain the expressions of \( \delta u_t \), \( \delta n_t \) and \( \delta \nu_t \). We first have \( \delta u_t = \dot{\xi}_t + [\xi_t, u_t] \); this comes from the standard Euler-Poincaré reduction theorem, as provided in [14, 18]. We also have \( \delta n_t = \delta (g_t \eta_t) = \varpi_t + \xi_t n_t \). From \( \nu_t = g_t \dot{\eta}_t \), we get \( \delta \nu_t = g_t \delta \dot{\eta}_t + \xi_t \nu_t \) and from \( \varpi_t = g_t \delta \eta_t \) we also have \( \dot{\varpi}_t = u_t \varpi_t + g_t \eta_t \). This yields \( \delta \nu_t = \dot{\varpi}_t + \xi_t \nu_t - u_t \varpi_t \).
We therefore obtain the system

\[ \int_0^1 \left( \left( \frac{\delta \ell}{\delta u} \right|_t \xi_t - \text{ad}_{u_t} \xi_t \right) + \left( \frac{\delta \ell}{\delta n_t} \right|_{\omega_t + \xi_t n_t} + \left( \frac{\delta \ell}{\delta \nu} \right|_{\xi_t + \xi_t \nu_t - u_t \omega_t} \right) \, dt = 0. \]

In the integration by parts to eliminate \( \dot{\xi}_t \) and \( \dot{\omega}_t \), the boundary term is \( (\langle \delta \ell / \delta u \rangle_1 | \xi_1 \rangle + (\langle \delta \ell / \delta \nu \rangle_1 | \omega_1 \rangle) \). Using the boundary condition, the last term can be rewritten as

\[ - (\langle \delta \ell / \delta \nu \rangle_1 | \xi_1 n_1 \rangle = (\langle \delta \ell / \delta \nu \rangle_1 \circ n_1 | \xi_1 \rangle). \]

We therefore obtain the boundary equation

\[ \frac{\delta \ell}{\delta u} (1) + \frac{\delta \ell}{\delta \nu} (1) \circ n_1 = 0. \]

The evolution equation for \( \xi \) is

\[ \frac{\partial}{\partial t} \frac{\delta \ell}{\delta u} + \text{ad}^*_{u_t} \frac{\delta \ell}{\delta u} + \frac{\delta \ell}{\delta n} \circ n_t + \frac{\delta \ell}{\delta \nu} \circ \nu_t = 0 \]

and the one for \( \varpi \) is

\[ \frac{\partial}{\partial t} \frac{\delta \ell}{\delta \nu} + u_t \star \frac{\delta \ell}{\delta \nu} - \frac{\delta \ell}{\delta n} = 0. \]

We therefore obtain the system

\[
\begin{cases}
\frac{\partial}{\partial t} \frac{\delta \ell}{\delta u} + \text{ad}^*_{u_t} \frac{\delta \ell}{\delta u} + \frac{\delta \ell}{\delta n} \circ n_t + \frac{\delta \ell}{\delta \nu} \circ \nu_t = 0, \\
\frac{\partial}{\partial t} \frac{\delta \ell}{\delta \nu} + u_t \star \frac{\delta \ell}{\delta \nu} - \frac{\delta \ell}{\delta n} = 0, \\
\frac{\delta \ell}{\delta u} (1) + \frac{\delta \ell}{\delta \nu} (1) \circ n_1 = 0, \\
\dot{n}_t = \nu_t + u_t n_t.
\end{cases}
\tag{5}
\]

The system (5) is equivalent to (4), since they characterize the same critical points. Direct evidence of this fact can be obtained by rewriting the first equation in (5) in the form:

\[ \frac{\partial}{\partial t} \left( \frac{\delta \ell}{\delta u} + \frac{\delta \ell}{\delta \nu} \circ u \right) + \text{ad}^*_{u_t} \left( \frac{\delta \ell}{\delta u} + \frac{\delta \ell}{\delta \nu} \circ u \right) = 0. \]

We indeed have, for a solution of (5),

\[
\begin{align*}
\frac{\partial}{\partial t} \left( \frac{\delta \ell}{\delta u} + \frac{\delta \ell}{\delta \nu} \circ n_t \right) &= \frac{\partial}{\partial t} \frac{\delta \ell}{\delta u} + \left( \frac{\delta \ell}{\delta \nu} \right) \circ n_t + \frac{\delta \ell}{\delta \nu} \circ \dot{n}_t \\
&= \frac{\partial}{\partial t} \frac{\delta \ell}{\delta u} + \left( \frac{\delta \ell}{\delta n} - u_t \star \frac{\delta \ell}{\delta \nu} \right) \circ n_t + \frac{\delta \ell}{\delta \nu} \circ (\nu_t + u_t n_t) \\
&= \frac{\partial}{\partial t} \frac{\delta \ell}{\delta u} + \frac{\delta \ell}{\delta n} \circ n_t + \frac{\delta \ell}{\delta \nu} \circ \nu_t - \left( u_t \star \frac{\delta \ell}{\delta \nu} \right) \circ n_t + \frac{\delta \ell}{\delta \nu} \circ (u_t n_t) \\
&= -\text{ad}^*_{u_t} \frac{\delta \ell}{\delta u} - \text{ad}^*_{u_t} \left( \frac{\delta \ell}{\delta \nu} \circ n_t \right).
\end{align*}
\]
In the last equation, we have used the fact that, for any \( \alpha \in \mathfrak{g} \),
\[
\left( \frac{\delta \ell}{\delta \nu} \circ (u \nu) - \left( u \frac{\delta \ell}{\delta \nu} \right) \circ n \right)(\alpha) = \left( \frac{\delta \ell}{\delta \nu} \right)(u\nu - u(n)) = -\left( \frac{\delta \ell}{\delta \nu} \right)(u, \alpha) n
\]
\[
= -\left( \frac{\delta \ell}{\delta \nu} \right)(\alpha) n + \left( \frac{\delta \ell}{\delta \nu} \right)(u, \alpha)
\]
\[
= -\left( \text{ad}_u^* \frac{\delta \ell}{\delta \nu} \circ n \right)(\alpha).
\]

This equation, combined with \((\delta \ell/\delta u)_1 + (\delta \ell/\delta \nu)_1 \circ u_1 = 0\), obviously implies the first equation in (3).

5. Special cases.

5.1. Riemannian metric. A primary application of this framework can be based on the
definition of a Riemannian metric on \( G \times N \) which is invariant for the action of \( G \):
\( (g, \eta)h = (gh, h^{-1}\eta) \), the corresponding Lagrangian then taking the form
\[
l(u, n, \nu) = \|(u, \nu)\|^2_n.
\]

The variational problem is now equivalent to the computation of geodesics for the
canonical projection of this metric from \( G \times N \) onto \( N \). This construction has been
introduced in [20]. The evolution equations have been derived and studied in [28] in the
case \( l(u, n, \nu) = |u|^2_\mathfrak{g} + |\nu|^2_n \), for a given norm, \( |\cdot|_\mathfrak{g} \), on \( \mathfrak{g} \) and a pre-existing Riemannian
structure on \( N \).

The interest of this construction is that this provides a Riemannian metric on \( N \)
which incorporates the group actions. Examples of this are given below for point sets
and images.

5.2. Semi-direct product. Assume that \( N \) is a group and that for all \( g \in G \),
the action of \( g \) on \( N \) is a group homomorphism: For all \( n, \tilde{n} \in N \), \( g(n\tilde{n}) = (gn)(g\tilde{n}) \) (for example,
\( N \) can be a vector space and the action of \( G \) can be linear). Consider the semi-direct
product \( G\circ N \) with \((g, n)(\tilde{g}, \tilde{n}) = (g\tilde{g}, (g\tilde{n})n) \) and build on \( G\circ N \) a right-invariant metric
constrained by its value \( \|(\text{id}_G, \text{id}_N)\) at the identity. Then, optimizing the geodesic energy
in \( G\circ N \) between \((\text{id}_G, n_0)\) and \((g_1, n_1)\) with fixed \( n_0 \) and \( n_1 \) and free \( g_1 \) yields a particular
case of metamorphoses.

Right invariance for the metric on \( G\circ N \) implies
\[
\|(U_g, \zeta)\|_{(g, n)} = \|(U_g \tilde{g}, (U_g \tilde{n})n + (g\tilde{n})\zeta)\|_{(g\tilde{g}, (g\tilde{n})n)},
\]
which, using \((\tilde{g}, \tilde{n}) = (g^{-1}, g^{-1}n^{-1})\), yields, letting \( u = U_g g^{-1} \),
\[
\|(U_g, \zeta)\|_{(g, n)} = \|(u, (u^{-1}n) + n^{-1}\zeta)\|_{(\text{id}_G, \text{id}_N)}
\]
\[
= \|(u, n^{-1}(\zeta - un))\|_{(\text{id}_G, \text{id}_N)}
\]
since \( 0 = u(n^{-1}n) = (un^{-1})n + n^{-1}(un) \). So, the geodesic energy on \( G\circ N \) for a path of
length 1 is
\[
\int_0^1 \|(u_t, n_t^{-1}(\dot{u}_t - u_tn_t))\|^2_{(\text{id}_G, \text{id}_N)}
\]
and optimizing this with fixed $n_0$ and $n_1$ is equivalent to solving the metamorphosis problem with

$$l(u, n, \nu) = \|(u, n^{-1}\nu)\|_{(id_G, id_N)}^2.$$  

(6)

This turns out to be a particular case of the previous example. The situation is even simpler when $N$ is a vector space with additive group operation, since this implies (identifying all tangent spaces on $N$) $n^{-1}\nu = \nu$ for all $n$ and the Lagrangian does not depend on $n$, which gives a very simple form to systems (4) and (5). They become

$$\begin{cases}
\frac{\delta \ell}{\delta u} + \frac{\delta \ell}{\delta \nu} \circ n_t = 0, \\
\frac{\partial}{\partial t} \frac{\delta \ell}{\delta \nu} + u_t \star \frac{\delta \ell}{\delta \nu} = 0, \\
\dot{n}_t = \nu_t + u_t n_t
\end{cases}$$  

(7)

and

$$\begin{cases}
\frac{\partial}{\partial t} \frac{\delta \ell}{\delta u} + \text{ad}^*_u \left( \frac{\delta \ell}{\delta u} \right) + \frac{\delta \ell}{\delta \nu} \circ \nu_t = 0, \\
\frac{\partial}{\partial t} \frac{\delta \ell}{\delta \nu} + u_t \star \frac{\delta \ell}{\delta \nu} = 0, \\
\frac{\delta \ell}{\delta u}(1) + \frac{\delta \ell}{\delta \nu}(1) \circ n_1 = 0, \\
\dot{n}_t = \nu_t + u_t n_t.
\end{cases}$$  

(8)

Even when $N$ is not a vector space, metamorphoses obtained from the semi-direct product formulation are specific among general metamorphoses, because they satisfy the conservation of momentum property which comes with every Lie group with a right-invariant metric. This conservation equation can be written

$$\left( \frac{\delta \ell}{\delta u}, \frac{\delta \ell}{\delta \nu} \right)_t = \text{Ad}_{(g_t, n_t)}^{-1} \left( \frac{\delta \ell}{\delta u}, \frac{\delta \ell}{\delta \nu} \right)_{t=0},$$

where the adjoint representation is the one associated to the semi-direct product. This property (which we do not make explicit in the general case) will be illustrated in some of the examples below.

5.3. Constrained metamorphoses. Returning to the general formulation, it is sometimes useful to include constraints on $n_t$, the image of the metamorphosis, making the minimization in (2) subject to $\Phi(n_t) = 0$ ($t \in [0, 1]$) for some function $\Phi : N \to \mathbb{R}^q$. 

Using Lagrange multipliers, this directly provides a new version of (4), yielding

\[
\begin{align*}
\frac{\delta \ell}{\delta u} + \frac{\delta \ell}{\delta \nu} \circ u_t &= 0, \\
\frac{\partial}{\partial t} \frac{\delta \ell}{\delta \nu} + u_t \star \frac{\delta \ell}{\delta \nu} &= \frac{\delta \ell}{\delta n} - \lambda^T \frac{\delta \Phi}{\delta n}, \\
\dot{n}_t &= \nu_t + u_t n_t, \\
\left( \frac{\delta \Phi}{\delta n} \right)_{\dot{n}_t} &= 0.
\end{align*}
\]

(9)

6. Examples from pattern matching. In the following examples and in the rest of the paper, \( G \) is a group of diffeomorphisms over some open subset \( \Omega \subset \mathbb{R}^d \). We will assume that elements of \( G \) can be obtained as flows associated to ordinary differential equations of the form \( \dot{g}_t = u_t \circ g_t \), where \( u_t \) is assumed to belong, at all times, to a Hilbert space \( \mathfrak{g} \) of vector fields on \( \Omega \) with the condition

\[
\int_0^1 \|u_t\|_G^2 dt < \infty.
\]

We will assume that elements of \( \mathfrak{g} \) are smooth enough, namely that \( V \) can be continuously embedded in the space of \( C^p \) vector fields with vanishing \( p \) first derivatives on \( \partial \Omega \) at infinity, for some \( p \geq 1 \). More details in this construction can be found in [27] (Appendix C).

We will write the inner product in \( \mathfrak{g} \) in the form

\[
\langle u, v \rangle_V = (L_{\mathfrak{g}} u \mid v),
\]

where \( L_{\mathfrak{g}} \) is the duality operator from \( \mathfrak{g} \) to \( \mathfrak{g}^* \). Its inverse, a kernel operator, will be denoted \( K_{\mathfrak{g}} \).

6.1. Landmarks and peakons. The space \( N \) contains the objects that are subject to deformations. The simplest case probably corresponds to configurations of \( Q \) landmarks, for which \( N = \Omega^Q \). So elements \( \eta, \nu \in H \) are \( Q \)-tuples of points in \( \Omega \), with tangent vectors being \( Q \)-tuples of \( d \)-dimensional vectors.

The model that has been proposed in [20, 5] corresponds to the Lagrangian

\[
\ell(u, n, \nu) = \|u\|_G^2 + \frac{1}{\sigma^2} \sum_{k=1}^Q |\nu^{(k)}|^2.
\]

This Lagrangian is therefore independent of \( n \) (but does not correspond to a semi-direct product). We have \( \delta \ell/\delta u = 2L_{\mathfrak{g}} u \) and \( (\delta \ell/\delta \nu) = (2/\sigma^2)(\nu^{(1)}, \ldots, \nu^{(Q)}) \). Let \( n = (q^{(1)}, \ldots, q^{(Q)}) \). From the definition \( (\delta \ell/\delta \nu) \circ n \mid w = - (\delta \ell/\delta \nu \mid w n) \), we get (since \( w n = (w(q^{(1)}), \ldots, w(q^{(Q)})) \)):

\[
\frac{\delta \ell}{\delta \nu} \circ n = - \sum_{k=1}^Q \frac{\nu^{(k)}}{\sigma^2} \otimes \delta q^{(k)}.
\]

Here and later, we use the following notation: if \( f \) is a vector field on \( \mathbb{R}^d \) (considered as a vector density) and if \( \mu \) is a measure on \( \mathbb{R}^d \), then the linear form \( f \otimes \mu \), acting on
THE EULER-POINCARE THEORY OF METAMORPHOSIS

vector fields, is defined by

\[ (f \otimes \mu | w) = \int_{\mathbb{R}^d} f(x)^T w(x) d\mu. \]  

Our first equation for landmark metamorphosis is therefore

\[ L_g u_t = \sum_{k=1}^{N} \frac{\nu_t^{(k)}}{\sigma^2} \otimes \delta_{q_t^{(k)}}. \]

The second equation is

\[ \frac{\partial}{\partial t} (\delta \ell / \delta \nu) + u^\star (\delta \ell / \delta \nu) = 0, \]

which in this case gives

\[ \dot{\nu}_t^{(k)} + D_{u_t} (q_t^{(k)})^T \nu_t^{(k)} = 0, \quad k = 1, \ldots, Q. \]

Introducing \( p^{(k)} = \nu^{(k)}/\sigma^2 \), we can rewrite system (4) in the form:

\[
\begin{align*}
L_g u_t &= \sum_{k=1}^{Q} p_t^{(k)} \otimes \delta_{q_t^{(k)}}, \\
\dot{p}_t^{(k)} + D_{u_t} (q_t^{(k)})^T p_t^{(k)} &= 0, \quad k = 1, \ldots, Q, \\
q_t^{(k)} &= u_t (q_t^{(k)}) + \sigma^2 p_t^{(k)}, \quad k = 1, \ldots, Q.
\end{align*}
\]

Putting the evolution equations into this form is interesting because the limiting case, \( \sigma^2 = 0 \), exactly corresponds to the peakon solution of the EPDiff equation [14], the dynamics of which having recently been described in [19]. It is important to see, however, that the solutions may have significantly distinct behavior when \( \sigma > 0 \). Figures 1 and 2 illustrate this in the case of two landmarks in 1D. The plots show the evolution of \( r = q_2 - q_1 \) over time when \( K_g = L_g^{-1} \) is a Gaussian kernel. Figure 1 provides a comparison in the case of a head-on collision \( (p_1 + p_2 = 0) \). In the case \( \sigma^2 = 0 \), the peakons approach each other infinitely closely in time without colliding. For positive \( \sigma^2 \), the peakons get close, slow down, then cross over and their distance grows rapidly to infinity. The duration of the collision phase \( (q \approx 0) \) decreases when the sum of the absolute momenta \( (p_1 - p_2) \) increases. Note that the deformation \( g_t \) never becomes singular during this process. The space first contracts when the peakons get closer, then expands after the crossover.

In Figure 2 the case of one peakon overtaking another is shown. In the case \( \sigma^2 = 0 \), we observe a well-known behavior: the peakons approach very closely, then separate again without crossing over. For metamorphoses \( (\sigma^2 > 0) \), the details of the behavior depend on the initial difference between the momenta. If it is small, then the evolution is similar to the case \( \sigma^2 = 0 \). When the initial momentum difference becomes larger, the peakon that started behind has enough energy to overpass the other one and the two peakons exchange position. In all cases, the deformations first experience a contraction, then an expansion (relative to the position of the two peakons).

6.2. Images. Now, consider the case when \( N \) is a space of smooth functions from \( \Omega \) to \( \mathbb{R} \), which we will call images, with the action \( (g, n) \mapsto n \circ g^{-1} \). A simple case of
metamorphoses \cite{20, 27} can be obtained with the Lagrangian

\[ \ell(u, \nu) = \|u\|_g^2 + \frac{1}{\sigma^2} \|\nu\|_{L^2}^2. \]

If \( w \in g \) and \( n \) is an image, \( wn = -\nabla n^T w \), so that \( (\delta \ell / \delta v \circ n) w = (\delta \ell / \delta v) \nabla n^T w \). Thus, since \( \delta \ell / \delta \nu = 2\nu / \sigma^2 \), the first equation is

\[ L_g u_t = -\frac{1}{\sigma^2} \nu_t \nabla n_t. \]
Fig. 3. Minimizing metamorphosis between images. The optimal trajectories for \(n_t\) are computed between the first and last images in each row. The remaining images show \(n_t\) at intermediate points in time.

Since \(u \ast (\delta \ell / \delta \nu)\) is defined by

\[
(u \ast \left( \frac{\delta \ell}{\delta \nu} \right)|_{\omega}) = \frac{\delta \ell}{\delta \nu} \mid_{u \omega} = -\left( \frac{\delta \ell}{\delta \nu} \mid \nabla \omega^T u \right) = -\frac{1}{\sigma^2} (\nu \mid \nabla \omega^T u) = \frac{1}{\sigma^2} (\text{div}(\nu u) \mid \omega),
\]

we obtain the second equation

\[
\dot{\nu} + \frac{1}{\sigma^2} \text{div}(\nu u_t) = 0.
\]

As in the landmark case, denote \(z = \nu / \sigma^2\) and rewrite the evolution equations in the form

\[
\begin{cases}
L_u u_t = -z_t \nabla n_t, \\
\dot{z}_t + \text{div}(z_t u_t) = 0, \\
\dot{n}_t + \nabla n_t^T u_t = \sigma^2 z_t.
\end{cases}
\tag{12}
\]

The existence and uniqueness of solutions for this system have been proved in [27]. From a visual point of view, image metamorphoses are similar to what is usually called “morphing” in computer graphics. The evolution of the image over time, \(t \mapsto n_t\), is a combination of deformations and image intensity variation. Algorithms and experimental results for the solution of the boundary value problem (minimize the Lagrangian between two images) can be found in [20, 9]. Some examples of minimizing geodesics are also provided in Figure 3.

In 1D, letting \(m = L_u u = (1 - \partial_x^2) u\), the time evolving form of this system (as provided by (9), or by direct computation from (10)) becomes, with \(\rho = \sigma z\):

\[
\partial_t m + u \partial_x m + 2m \partial_x u = -\rho \partial_x \rho \quad \text{with} \quad \partial_t \rho + \partial_x (\rho u) = 0. \tag{13}
\]

License or copyright restrictions may apply to redistribution; see http://www.ams.org/license/jour-dist-license.pdf
This relates, with the important difference of a minus sign in front of $\rho \partial_x \rho$ in the first equation, to the two-component Camassa-Holm system studied in [6, 8, 17]. The system (13) in our case is equivalent to the compatibility for $d\lambda/dt = 0$ of

$$\partial_x^2 \psi + \left(-\frac{1}{4} + m\lambda + \rho^2 \lambda^2\right)\psi = 0,$$

$$\partial_t \psi = -\left(\frac{1}{2\lambda} + u\right)\partial_x \psi + \frac{1}{2} \psi \partial_x u.$$  

Image matching can also be seen under the semi-direct product point of view, since the action is linear and the Lagrangian takes the form (6) with $n^{-1} \nu = \nu$. This implies that the momentum, which is, in this case, the pair $(L_g u, z)$, is conserved in a fixed frame. Working out the conservation equation $\text{Ad}_{(g,n)} (L_g u, z) = \text{cst}$ in this case yields the equations $L_g u_t + z_t n_t = \text{cst}$ and $z_t = \det(Dg^{-1}) z_0 \circ g^{-1}$. This last condition is the integrated form of the second equation in (12), while the first equation in (12) implies that in fact $L_g u_t + z_t n_t = 0$, which is the horizontality condition in the quotient space $G\mathbb{S}N/G$.

6.3. Densities. We here let $N$ be a space of smooth functions $n : \Omega \to \mathbb{R}$ with the action $(g, n) \mapsto |\det D(g^{-1})| n \circ g^{-1}$; i.e., $n$ deforms as a density. We consider the same Lagrangian as with images,

$$\ell(u, \nu) = \frac{1}{2} \|u\|^2_\theta + \frac{1}{2\sigma^2} \|\nu\|^2_L.$$

For $w \in g$ and $n \in H$, we have $wn = -\nabla n^T w - n \text{div}(w) = -\text{div}(nw)$. This implies

$$\left(\frac{\delta \ell}{\delta \nu} n \big| w\right) = -\frac{1}{\sigma^2} (\nu | \text{div}(nw))$$

$$= \frac{1}{\sigma^2} (n \nabla \nu \big| w),$$

yielding the first equation

$$L_g u = \frac{1}{\sigma^2} n \nabla \nu.$$  

Similarly, we get $u \star \nu = \nabla \nu^T u$ and the equation

$$\dot{\nu} + \nabla \nu^T \nu = 0.$$  

This yields the system, where we have, as before, introduced $z = \nu/\sigma^2$:

$$\begin{cases} 
L_g u = n \nabla z, \\
\dot{z} + \nabla z^T u = 0, \\
\dot{n} + \text{div}(nu) = \sigma^2 z.
\end{cases}$$

(16)

We are here also in the semi-direct product case, the equations for the conservation of momentum being $L_g u + n \nabla z = \text{cst}$ and $z = z_0 \circ g^{-1}$. As for images, the constant in the first conservation equation vanishes for horizontal geodesics in $G\mathbb{S}N/G$. Optimal metamorphoses with densities are illustrated in Figure 4.
6.4. Plane curves. We here consider matching unit-length curves $\gamma$ defined on the unit circle $S^1$, represented, as in [32, 21, 33], with their normalized tangent $\theta \mapsto \dot{\gamma}_{\theta}$ with $|\dot{\gamma}_{\theta}| = 1/(2\pi)$. The set $N$ is therefore a set of functions $n : S^1 \to S^1(1/(2\pi))$, where $S^1(r)$ is the sphere with radius $r$ in $\mathbb{R}^2$. We let $G$ be the group of diffeomorphisms of $S^1$ and consider the reduced Lagrangian

$$\ell(u, \nu) = \int_{S^1} \dot{\gamma}_{\theta}^2 d\theta + \frac{1}{\sigma^2} \int_{S^1} |\nu|^2 d\theta.$$ 

We want to solve the metamorphosis problem while ensuring that curves are closed, which translates into:

$$\int_{S^1} n_{\theta} d\theta = 0.$$ 

To make (17) explicit, we need a local chart to compute the partial derivatives $\partial/\partial \nu$ and $\partial/\partial n$ ($N$ is not a vector space here). Consider the representation $n = h_\alpha$ and $\nu = \sigma^2 \rho h_\alpha^\perp$ with $h_\alpha = (\cos \alpha, \sin \alpha)$ and $h_\alpha^\perp = (-\sin \alpha, \cos \alpha)$. We then get the equations, with $\lambda_t \in \mathbb{R}^2$,

$$\begin{align*}
\frac{\partial^2 u_t}{\partial \theta^2} + \rho_t \frac{\partial \alpha_t}{\partial \theta} & = 0, \\
\frac{\partial \rho_t}{\partial t} + \frac{\partial}{\partial \theta}(u_t \rho_t) & = -\lambda_t^T h_\alpha^+, \\
\dot{\alpha}_t & = \sigma^2 \rho_t - u_t \frac{\partial \alpha_t}{\partial \theta}, \\
\int_{S^1} \dot{\alpha}_t h_\alpha^+ d\theta & = 0.
\end{align*}$$

Interestingly, these equations can be notably simplified in the case $\sigma^2 = 1$, which has been considered in [32, 25, 26, 33]. In this case, the change of variables $z_t^2 = \dot{g}_t n_t \circ g_t$, where both sides are interpreted as complex numbers, reduces (17) to geodesic equations on a Grassmann manifold, on which explicit computations can be made [33]. The case
σ^2 = 4 is also interesting, and has been discussed in [15]. Figure 5 provides the result of curve metamorphosis using σ^2 = 1.

7. Measure metamorphoses. We now focus on extending the example in section 6.3 to also include singular measures. The L^2-norm that we have used between densities is therefore no longer available. We will rely on a construction that was introduced in [10].

We let H be a reproducing kernel Hilbert space (RKHS) of functions over R^d and N = H^*; H being an RKHS is equivalent to the fact that for all x ∈ R^d, there exists a function K_x ∈ H such that, for all f ∈ H, ⟨K_x, f⟩_H = f(x). The kernel K_H(x, y) := K_x(y) satisfies the equation ⟨K_x, K_y⟩_H = K_H(x, y). It also provides an isometry between N and H via the relation η → K_Hη with ⟨K_Hη, f⟩_H = ⟨η | f⟩. This implies in particular that the dual inner product on N is given by

⟨η, ˜η⟩_N = ⟨η | K_H ˜η⟩.

Letting G be as in the previous section, we want to study metamorphoses in G × N. We define the action of G on N by (with g ∈ G, η ∈ N and f ∈ H)

(gη | f) = ⟨η | f ◦ g⟩.

This obviously generalizes the action on densities discussed in the previous section. For η ∈ N and w ∈ g, we have, for all f ∈ H, (wη | f) = ⟨η | ∇f^T w⟩.

Since the action is linear, we can use the semi-direct product model and the Lagrangian

ℓ(u, ν) = \frac{1}{2}∥u∥_g^2 + \frac{1}{2σ^2}∥ν∥_N^2.

To explicitly compute again (4) in this context, we need to compute (δℓ/δν) ◦ n. We let f = δℓ/δν = (1/σ^2)K_Hν. By definition, we have, for all w ∈ g,

(f ◦ n | w) = -(f | wn)
= -(n | ∇f^T w)
= -(∇f ◦ n | w).
We therefore obtain our first equation \((\delta \ell / \delta u) = \nabla f \otimes \nu\). Since \((f \mid un) = (\eta \nabla f^T u)\), the second equation, \(\dot{f} + u \otimes f_t = 0\), is the advection: \(\dot{f} + \nabla^T f_t u_t = 0\). This yields the system (with \(L_H = K_H^{-1}\))

\[
\begin{cases}
L_g u_t = \nabla f_t \otimes n_t, \\
\dot{f_t} + \nabla^T f_t u_t = 0, \\
\dot{n_t} - u_t n_t = \sigma^2 L_H f_t.
\end{cases}
\]  

From the second equation, we get \(f_t = f_0 \circ g_t^{-1}\). Using \(g \dot{\eta} = \nu = \sigma^2 L_H f\) and \(g \eta = n\), we get

\[n_t = g_t n_0 + \sigma^2 g_t \int_0^t g_s^{-1} K_H^{-1}(f_0 \circ g_s^{-1}) ds.\]

We therefore obtain integrated equations for measure metamorphoses

\[
\begin{cases}
L_g u_t = \nabla f_t \otimes n_t, \\
n_t = g_t n_0 + \sigma^2 g_t \int_0^t g_s^{-1} L_H (f_0 \circ g_s^{-1}) ds
\end{cases}
\]  

with \(\dot{g}_t = u_t \circ g_t\).

We now pass to the theoretical study of the existence of solutions for the initial value problem (IVP) and boundary value problem (BVP) for measure metamorphosis (with uniqueness in the IVP case). The next two sections are notably more technical than the rest of this paper. They are well isolated from it, however, and it is possible, if desired, to skip directly to section 10.

### 8. Existence of solutions for the measure metamorphosis IVP.

For the existence proofs to proceed, we need some conditions on the Hilbert spaces \(g\) and \(H\). They are essentially adapted to \(H\) being equivalent to \(H^q\) (the completion, in \(H^q\), of \(C^\infty\) functions with compact support), in which case \(H^- = H^q_0^{-1}\) and \(H^+ = H^q_0^{-1} (q\) being large enough to ensure that \(H^q\) is embedded in \(C^0\)).

In the following, \(\text{cst}\) represents a generic constant, and \(C\) a generic continuous function of its parameters. We assume the existence of two spaces \(H^+\) and \(H^-\) and the following properties, valid for some \(q \geq 1\).

1. \((H1)\) If \(\tilde{H} = H^-, H\) or \(H^+\), we have: if \(f \in \tilde{H}\) and \(g \in C^q(\Omega)\), then \(f \circ g \in \tilde{H}\) and

\[\|f \circ g\|_{\tilde{H}} \leq C(\|g\|_{q, \infty}) \|f\|_{\tilde{H}}.\]

2. \((H2)\) For \(f \in H^+\), and \(g, \tilde{g}\) two \(C^q\) diffeomorphisms,

\[\|f \circ g - f \circ \tilde{g}\|_{\tilde{H}} \leq \text{cst} \|f\|_{H^+} C(\max(\|g\|_{q, \infty}, \|\tilde{g}\|_{q, \infty})) \|g - \tilde{g}\|_{q, \infty}.\]

3. \((H3)\) For \(f \in H\), define the operator \(Q_f\) on \(g\) by \(Q_f w = \nabla f^T w\). Then for all \(f \in H\) and \(g \in C^q(\Omega)\), \(Q_f\) maps \(X^q(\Omega)\) to \(H^-\) with

\[\|Q_f w\|_{H^-} \leq \text{cst} \|f\|_{H} \|w\|_{q, \infty}\].
for all \( w \in \mathcal{X}^q(\Omega) \). (Here, \( \mathcal{X}^q(\Omega) \) denotes the set of \( C^q \) vector fields on \( \Omega \) with the supremum norm of all derivatives of order less than \( q \).)

(H4) If \( f \in H^+ \), then \( K_H^{-1} f \in (H^-)^* \) and for all \( z \in H^- \), \( (K_H^{-1} f | z) \leq \text{cst} \| f \|_{H^+} \| z \|_{H^-} \).

(H5) \( \mathcal{g} \) is continuously included in \( \mathcal{X}_0^p(\Omega) \) for \( p > q + 1 \), where \( \mathcal{X}_0^p(\Omega) \) is the completion of compactly supported vector fields in \( \mathcal{X}^p(\Omega) \).

Denote \( N^+ = (H^-)^* \). We then have

**Theorem 1.** Under the hypotheses (H1) to (H3), for all \( T > 0 \), there exists a unique solution to system \([19]\) over \([0, T]\) with initial conditions \( n_0 \in N^+ \) and \( f_0 \in H^+ \).

**Proof.** We prove existence for small enough \( T \) with a fixed point argument. Consider the Hilbert space \( L^2([0, T], \mathcal{g}) \), with norm

\[
\| u \|_{2, T}^2 = \int_0^T \| u_t \|_{\mathcal{g}}^2 dt.
\]

For \( u \in L^2([0, T], \mathcal{g}) \), define \( \Psi(u) := u' \) given by

\[
\begin{align*}
\dot{u}_t &= K_\mathcal{g}(\nabla f_t \otimes n_t), \\
n_t &= g_t n_0 + \sigma^2 g_t \int_0^t g_s^{-1} L_H f_0 \circ g_t^{-1} ds
\end{align*}
\]

with \( \dot{g}_t = u_t \circ g_t \).

First note that the hypotheses imply that \( \Psi \) is well defined and takes values in \( L^2([0, T], \mathcal{g}) \). Indeed, by definition,

\[
\langle u', w \rangle_\mathcal{g} = (\nabla f_t \otimes n_t | w) = (n_t | \nabla f_t w) \leq \text{cst} \| n_t \|_N \| f_t \|_{H^+} \| w \|_{\mathcal{g}, \infty} \leq \text{cst} \| n_t \|_N \| f_t \|_{H^+} \| w \|_{\mathcal{g}}
\]

so that a sufficient condition for \( \nabla f_t \otimes n_t \in \mathcal{g}^* \) is \( n_t \in N \) and \( f_t \in H^+ \). Since \( f_t = f_0 \circ g_t^{-1} \), we have \( \| f_t \|_{H^+} \leq \text{cst} \| f_0 \|_{H^+} + C(\| g_t^{-1} \|_{q, \infty}) \). From \([21]\), we have \( \| g_t^{-1} \|_{q, \infty} = O(\| u \|_{2, T}) \), yielding

\[
\| f_t \|_{H^+} \leq \text{cst} \| f_0 \|_{H^+} + C(\| u \|_{2, T}).
\]

For \( z \in H \), we have

\[
(n_t | z) = (n_0 | z \circ g_t) + \sigma^2 \int_0^t (K_H^{-1} f_s | z_s \circ g_t \circ g_s^{-1}) ds 
\leq \left( \| n_0 \|_N C(\| g_t \|_{q, \infty}) + \sigma^2 \int_0^t \| f_s \|_{H} C(\| g_t \circ g_s^{-1} \|_{q, \infty}) ds \right) \| z \|_H
\]

so that

\[
\| n_t \|_N \leq \left( \| n_0 \|_N + \sigma^2 t \| f_0 \|_H \right) C(\| u \|_{2, T}).
\]

This implies that

\[
\| u_t \|_{\mathcal{g}} \leq \| f_0 \|_{H^+} \left( \| n_0 \|_N + \sigma^2 t \| f_0 \|_H \right) C(\| u \|_{2, T})
\]
and
\[ \|u\|_{2,T}^2 \leq \text{cst} \sqrt{T} \|f_0\|_{H^+} \left( \|n_0\|_N + \sigma^2 T \|f_0\|_H \right) C(\|u\|_{2,T}). \]

In particular, this implies that, for any \( M > 0 \), there exists a \( T_0(M) \) (only depending on \( \|n_0\|_N + \|f_0\|_{H^+} \)) such that, for \( T < T_0 \), \( \|u\|_{2,T} \leq M \) implies \( \|u'\|_{2,T} \leq M \). From now on, we assume that \( T < T_0(M) \) with \( M = 1 \).

Note that a similar computation also shows that \( n_t \in N^+ \): for \( z \in H^- \), we have
\[ (n_t, z) = \left( n_0, z \circ g_t \right) + \sigma^2 \int_0^t \left( \int_0^1 (K_{H}^{-1} f_s) z_s \circ g_t \circ g_s^{-1} \right) ds \]
\[ \leq \left( \left( \|n_0\|_N \right) + \sigma^2 C \left( \|f_0\|_{H^+} \right) \right) \|z\|_{H^-}, \]
so that
\[ \|n_t\|_{N^+} \leq \left( \|n_0\|_{N^+} + \sigma^2 C \|f_0\|_{H^+} \right) C(\|u\|_{2,T}). \quad (23) \]

We now ensure that \( \Psi \) is contractive. Take \( u, \tilde{u} \) with \( \max(\|u\|_{2,T}, \|\tilde{u}\|_{2,T}) \leq 1 \). We want to show that \( T \) can be chosen so that \( \|u' - \tilde{u}'\|_{2,T} \leq \rho |u - \tilde{u}|_{2,T} \) with \( \rho < 1 \), where \( u' = \Psi(u) \) and \( \tilde{u}' = \Psi(\tilde{u}) \). We have
\[ \|u' - \tilde{u}'\|_0 = \|\nabla f_t \otimes n_t - \nabla \tilde{f}_t \otimes \tilde{n}_t\|_{g^*} \]
\[ \leq \|\nabla (f_t - \tilde{f}_t) \otimes n_t\|_{g^*} + \|\nabla \tilde{f}_t \otimes (n_t - \tilde{n}_t)\|_{g^*} \]
\[ \leq \text{cst} \|n_t\|_{N^+} \|f_t - \tilde{f}_t\|_H + \text{cst} \|n_t - \tilde{n}_t\|_{N^+} \|f_t\|_{H^+}. \]

(Here, we have used the fact that for \( n \in N^+ \) and \( z \in H \), we have both \( (n, z) \leq \|n\|_N \|z\|_H \) and \( (n, z) \leq \|n\|_{N^+} \|z\|_{H^-} \)).

Upper bounds for \( \|f_t\|_{H^+}, \|n_t\|_N \) and \( \|n_t\|_{N^+} \) are provided by equations (21), (22) and (24).

Moreover, from (H2), we have
\[ \|f_t - \tilde{f}_t\|_H \leq C(\max(\|g_t^{-1}\|_{q,\infty}, \|g_t^{-1}\|_{q,\infty}) \|f_0\|_{H^+} + \|g_t - \tilde{g}_t\|_{q,\infty}) \]
and, using (24), we have \( \|g_t^{-1} - \tilde{g}_t^{-1}\|_{q+1,\infty} \leq \text{cst} \|u - \tilde{u}\|_{2,T} \) so that
\[ \|n_t\|_{N^+} \|f_t - \tilde{f}_t\|_H \leq \text{cst} (\|n_0\|_{N^+} + \sigma^2 C \|f_0\|_{H^+}) \|f_0\|_{H^+} \|u - \tilde{u}\|_{2,T}. \]

For \( z \in H \), we can write
\[ (n_t - \tilde{n}_t, z) = \left( n_0, z \circ g_t - z \circ \tilde{g}_t \right) \]
\[ + \sigma^2 \int_0^t \left( K_{H}^{-1} f_s \circ g_t \circ g_s^{-1} - z \circ \tilde{g}_t \circ \tilde{g}_s^{-1} \right) ds \]
\[ + \sigma^2 \int_0^t \left( K_{H}^{-1} (f_s - \tilde{f}_s) \circ g_t \circ g_s^{-1} \right) ds \]
\( (i) \leq \text{cst} \|n_0\|_{N^+} \|z\|_H \|g_t - \tilde{g}_t\|_{q,\infty} \]
\( (ii) \leq \text{cst} \sigma^2 C \|f_0\|_{H^+} \|z\|_H \max_s \|g_t \circ g_s^{-1} - \tilde{g}_t \circ \tilde{g}_s^{-1}\|_{q,\infty} \]
\( (iii) \leq \text{cst} \sigma^2 C \|f_0\|_{H^+} \|z\|_H \max_s \|g_t - \tilde{g}_t\|_{q,\infty} \|g_t \circ g_s^{-1} - \tilde{g}_t \circ \tilde{g}_s^{-1}\|_{q,\infty}. \]

For (i), we have used
\[ \left( n_0, z \circ g_t - z \circ \tilde{g}_t \right) \leq \|n_0\|_{N^+} \|z\|_H \leq \text{cst} \|n_0\|_{N^+} \|z\|_H \|g_t - \tilde{g}_t\|_{p,\infty}. \]
For (ii), we have used the same argument combined with the fact that, since $f_s \in H^+$, $K_H^{-1} f_s \in N^+$ with $\|K_H^{-1} f_s\|_{N^+} \leq \text{cst} \|f_s\|_{H^+}$. For (iii), the computation uses the fact that for $\tilde{z} \in H$,

$$(K_H^{-1}(f_s - \tilde{f}_s)) \tilde{z} \leq \|f_s - \tilde{f}_s\|_H \|\tilde{z}\|_H.$$  

We therefore obtain the inequality

$$\|n_t - \tilde{n}_t\|_H \leq \text{cst}(\|n_0\|_{N^+} + \|f_0\|_{H^+})\|u - \tilde{u}\|_{2,T}. \quad (25)$$

Collecting the previous estimates, we have

$$\|u' - \tilde{u}'\|_{2,T} \leq F(\|n_0\|_{N^+}, \|f_0\|_{H^+})\|u - \tilde{u}\|_{2,T},$$

where $F$ is a polynomial. This implies

$$\|u' - \tilde{u}'\|_{2,T} \leq \sqrt{T} F(\|n_0\|_{N^+}, \|f_0\|_{H^+})\|u - \tilde{u}\|_{2,T},$$

so that $\Psi$ is contractive for small enough $T$.

The extension from small times to all times can be done as in [27], and we only sketch the details. According to the small time computation, the length over which the solution exists is at least the inverse of a polynomial function of $\|n_0\|_{N^+}$ and $\|f_0\|_{H^+}$. One will therefore be able to extend this equation beyond $T$, unless either $\|n_t\|_{N^+}$ or $\|f_t\|_{H^+}$ tends to infinity when $t$ tends to $T$. From (21) and (22), this can happen only if $\|u\|_{2,T}$ tends to infinity when $t$ tends to $T$. But this is impossible, because (19) is a geodesic equation on $G \otimes N$ which implies that the value of $h_t := \|u_t\|^2 + (1/\sigma^2)\|\nu_t\|^2_N$ is constant over time. This implies in particular that $\|u\|^2_{2,T} \leq t h_0$ and therefore cannot tend to infinity in finite time.

9. Existence of solutions for the measure metamorphosis BVP. Our goal in this section is to prove that, under some conditions on $H$, the boundary value problem for measure metamorphoses (BVP) always has solutions. This problem requires us to minimize, with fixed $n_0$ and $n_1$,

$$E(u, n) := \int_0^1 \|u_t\|^2_0 dt + \frac{1}{\sigma^2} \int_0^1 \|\tilde{n}_t - u_t n_t\|^2_\gamma dt.$$  

Letting $f_t = K_H(\tilde{n}_t - u_t n_t)$, the problem is equivalent to minimizing

$$E(u, f) := \int_0^1 \|u_t\|^2_0 dt + \sigma^2 \int_0^1 \|f_t\|^2_H dt$$

with boundary

$$n_1 = g_1 n_0 + \sigma^2 g_1 \int_0^1 g_s^{-1}(K_H^{-1} f_s) ds.$$  

We have

**Theorem 2.** Assume that (H1) and (H2) hold and that $H^+$ is dense in $H$. Then, for any given $n_0, n_1 \in H$, there exists a minimizer for the BVP.
Proof. Consider a minimizing sequence \((u^{(k)}, f^{(k)})\). Using a time change if necessary, we can ensure that 
\[ c_k := \|u^{(k)}\|_p^2 + \sigma^2\|f^{(k)}\|_2^2 \]
is independent of time and therefore bounded. Moreover, we can extract a subsequence (still denoted \((u^{(k)}, f^{(k)})\)) which
weakly converges to some \((u, f)\) in \(L^2([0, 1], g \times H)\), equipped with the norm \(\|u', f'\| = E(u', f')\). This implies that
\(E(u, f) \leq \liminf E(u^{(k)}, f^{(k)})\) so that the only thing that
needs to be shown is that the boundary condition is still satisfied; namely, letting
\[ n'_1 = g_1 n_0 + \sigma^2 g_1 \int_0^1 g_s^{-1} (K^{-1}_H f_s) ds \]
with \(g_t = u_t \circ g_t\), we have \(n'_1 = n_1\). For this, it suffices to show that, for \(z\) in a dense
subset of \(H\), we have \(\langle n'_1, z \rangle = \langle n_1, z \rangle\). Since, for all \(k\), we have
\[ n_1 = g^{(k)}_1 n_0 + \sigma^2 g^{(k)}_1 \int_0^1 (g^{(k)}_s)^{-1} (K^{-1}_H f^{(k)}_s) ds, \]
it suffices to show that, for \(z\) in a dense subset of \(H\), we have
\[ \langle n_0, z \circ g^{(k)}_1 \rangle \to \langle n_0, z \circ g_1 \rangle \] 
and
\[ \int_0^1 (K^{-1}_H f^{(k)}_s) z \circ g^{(k)}_1 (g^{(k)}_s)^{-1} ds \to \int_0^1 (K^{-1}_H f_s) z \circ g_1 (g^{-1}_s) ds. \] 

Because of the weak convergence of \(u^{(n)}\) to \(u\), the flows \(g^{(n)}\) converge to \(g\) for the
\((p - 1, \infty)\)-norm, uniformly in time [27]. Taking \(z \in H^+\), we have
\[ \langle n_0, z \circ g^{(k)}_1 - z \circ g_1 \rangle \leq C(\sup_t \|g^{(k)}_t\|_{p, \infty}, \|g_t\|_{p, \infty}) \|n_0\|_{H^+} \|z\|_{H^+} \sup_t \|g^{(k)}_t - g_t\|_{p, \infty}, \]
which tends to 0 so that (26) is true for all \(z \in H^+\). Splitting the terms in (27), it suffices to show that for all \(s \in [0, 1]\),
\[ \int_0^1 (K^{-1}_H f^{(k)}_s) z \circ g^{(k)}_1 (g^{(k)}_s)^{-1} ds - \int_0^1 (K^{-1}_H f^{(k)}_s) z \circ g_1 (g^{-1}_s) \to 0 \] 
and
\[ \int_0^1 (K^{-1}_H f^{(k)}_s) z \circ g_1 (g^{-1}_s) ds - \int_0^1 (K^{-1}_H f_s) z \circ g_1 (g^{-1}_s) ds \to 0. \] 

For (28), and because we have ensured that \(\|f^{(k)}_s\|_H\) and \(\|u^{(k)}_s\|_B\) are uniformly bounded,
it suffices to show that each term in the integral tends to 0 and then use the dominated
convergence theorem. The left-hand term of (28) is bounded in absolute value by
\[ \text{cst}\|f^{(k)}_s\|_H \|z\|_{H^+} \|g^{(k)}_1 (g^{(k)}_s)^{-1} - g_1 (g^{-1}_s)\|_{p, \infty}, \]
which tends to 0, so that (28) holds. To prove (29), we only need the fact that \(z \circ g_1 (g^{-1}_s)\)
belongs to \(H\) and the weak convergence of \(f^{(k)}\) to \(f\).

This shows that \(n'_1 = n_1\) and concludes the proof of the theorem. \(\square\)
9.1. Remark. Equations (19) have been obtained from general formulae that were derived under the assumption that $G$ is a Lie group (which is not the case here). It is important to rigorously recompute the Euler equation to reconnect the IVP and the BVP. The variation with respect to $u$ is straightforward and provides the first equation in (19).

We now discuss the minimization in $n$ with fixed $u$. Letting $\eta = g^{-1}n$ the problem with fixed $u$ (and therefore fixed $g$) is equivalent to the minimization of

$$F(\eta) = \int_0^1 \|g_{\eta_t}\|_{L}^2 dt$$

with fixed boundary conditions $\eta_0 = n_0$ and $\eta_1 = g_1^{-1}n_1$.

Assume the following hypothesis:

(H1b) $z \rightarrow z \circ g$ is weakly continuous for $z \in H$ (where $H^* = N$).

For $g \in G$, introduce the operator $K_H^\eta$ defined by $K_H^\eta \eta = K_H(g\eta) \circ g$. With this notation,

$$F(\eta) = \int_0^1 (\dot{\eta}_t \mid K_H^\eta \dot{\eta}_t) dt.$$

Let $L_H^\eta = (K_H^\eta)^{-1}$, i.e., $L_H^\eta f = g^{-1}L_H(f \circ g^{-1})$, and denote

$$\bar{L}_H^\eta = \int_0^1 L_H^\eta dt.$$ (30)

We have for any $f \in H$,

$$(\bar{L}_H^\eta f \mid f) = \int_0^1 (L_H^\eta f \mid f) dt = \int_0^1 \|f \circ g_t^{-1}\|_{L}^2 dt \geq C\|f\|_{L}^2,$$ (31)

where the last inequality comes from (H1) with $C = [\sup_{t} C(\|g_t^{-1}\|_{q, \infty})]^{-1}$. Thus, $\bar{L}_H^\eta f = 0$ if and only if $f = 0$ and $\bar{L}_H^\eta(H)$ is dense in $H^*$. If we prove that $\bar{L}_H^\eta(H)$ is closed, we will get that $\bar{L}_H^\eta(H) : H \rightarrow H^*$ is invertible. Let $(f_n)_{n \geq 0}$ be a sequence in $H$ and $\eta \in H^*$ such that $\bar{L}_H^\eta(f_n) \rightarrow \eta$ in $H^*$. Then we get from (31) that $f_n$ is bounded in $H$ and we can assume that it admits a weak limit $f_{\infty}$ in $H$. Thus $(\bar{L}_H^\eta f_{\infty} \mid f) = \int_0^1 (f_{\infty} \circ g_t^{-1}, f \circ g_t^{-1})_H dt = \lim_{n \rightarrow \infty} \int_0^1 (f_n \circ g_t^{-1}, f \circ g_t^{-1})_H dt$, where the last equality comes from (H1b) and the dominated convergence theorem. This yields $(\bar{L}_H^\eta f_{\infty} \mid f) = (\eta \mid f)$ for any $f \in H$ so that $\eta = \bar{L}_H^\eta f_{\infty}$ and $\bar{L}_H^\eta(H)$ is closed.

Let $f_0$ be such that $\bar{L}_H^\eta f_0 = \eta_1 - \eta_0$ and define

$$\hat{\eta}_t = \eta_0 + \int_0^t \bar{L}_H^\eta f_0 ds$$ (32)

for any $t \in [0, 1]$. We now prove that, for any $(\hat{\eta}_t) \in L^2([0, 1], H^*)$ with $\eta_1$ and $\eta_0$ fixed,

$$F(\eta - \hat{\eta}) = F(\eta) + \text{cst.}$$

We have

$$F(\eta - \hat{\eta}) = F(\eta) + F(\hat{\eta}) - 2 \int_0^1 (\hat{\eta}_t \mid K_H^{\eta_0} \hat{\eta}_t) dt$$

and $\int_0^1 (\hat{\eta}_t \mid K_H^{\eta_0} \hat{\eta}_t) dt = \int_0^1 (\hat{\eta}_t \mid f_0) dt = (\eta_1 - \eta_0) f_0$, so that the result is proved.
We therefore have proved that minimizing E with respect to \( u, n \) is the same as minimizing
\[
\tilde{E}(u) = \int_0^1 \| u_t \|_0^2 dt + \frac{1}{\sigma^2} (\eta_1 - \eta_0) [\tilde{L}_H^\alpha]^{-1}(\eta_1 - \eta_0)
\]
with respect to \( u \). We also have the expression [52] for the optimal \( \eta \) which is consistent with the second equation in (19).

10. A computational ansatz for point measure matching. The previous theorems provide a rigorous foundation for the measure matching approach being considered. However, an important issue needs to be addressed. The space \( N \), which has been introduced in order to take advantage of its Hilbert structure, is a big space that contains distributions that are more singular than measures. Now, when matching two measures \( n_0 \) and \( n_1 \), the question naturally arises of whether the optimal evolution, i.e., the measure \( n_t \), can turn up being more singular than measures, since the existence theorem only ensures that it belongs to \( N \).

The second equation in (19) indicates that this should not be the case, since it says that
\[
n_t = g_t n_0 + g_t \int_0^t \tilde{L}_H^\alpha (\tilde{L}_H^\alpha)^{-1} (g_1^{-1} n_1 - n_0) ds,
\]
where \( \tilde{L}_H^\alpha \) and \( \tilde{L}_H^\beta \) are defined above and in equation (31). Thinking of \( L_H \) as a differential operator, the number of derivatives computed by \( L_H \) is “canceled” by the pre-application of \( (L_H^\alpha)^{-1} \) so that \( n_t \) should not be more singular than \( (g_1^{-1} n_1 - n_0) \), which is a measure. It is therefore reasonable to conjecture that when \( n_0 \) and \( n_1 \) are weighted sums of Dirac measures (which is a case of practical interest), then \( n_t \) is a measure which has an absolutely continuous part, and a singular part which is also a sum of Dirac measures. More precisely, if
\[
n_0 = \sum_{k=1}^{q} \alpha_k^{(0)} \delta_{x_k^{(0)}}, \quad n_1 = \sum_{k=1}^{r} \beta_k^{(1)} \delta_{y_k^{(1)}},
\]
a reasonable ansatz for \( n_t \) is
\[
n_t = \sum_{k=1}^{r} \alpha_k(t) \delta_{x_k(t)} + \sum_{k=1}^{r} \beta_k(t) \delta_{y_k(t)} + f(t, .) dx.
\]

Assuming this, the Lagrangian \( \ell(v_t, n_t, \nu_t) \) can be considered as a function of \( (\alpha_k(t)), (\beta_k(t)), (x_k(t)), (y_k(t)), f(t, .) \) and their time derivatives, with an explicit expression in terms of the kernel \( K_H \) and its space derivatives that we do not provide here, since it is quite lengthy. Minimization can then be done with standard methods, with boundary conditions \( \alpha_k(0) = \alpha_k^{(0)}, \beta_k(0) = 0, \alpha_k(1) = 0, \beta_k(1) = \beta_k^{(1)}, x_k(0) = x_k^{(0)}, y_k(1) = y_k^{(1)} \) and \( f(0, .) = f(1, .) = 0 \).

11. More metamorphosis. Without getting into the level of rigor and detail developed with measure metamorphosis, we now review additional situations in which metamorphoses can be used. At the difference of the examples considered in section 6, the following models have not yet been solved numerically, nor has a theoretical analysis
been developed although we expect that the previous proofs of existence of solutions can be modified to work in these cases also.

11.1. Singular image metamorphosis. In section 7 we have extended density metamorphosis to a context that includes singular measures. A similar analysis can be made to extend image metamorphosis to generalized functions. Let $H$ be a space of smooth scalar functions and $N = H^*$ as before. The extension to $N$ of the action of diffeomorphisms on images is $(g,n) \mapsto gn$ with

$$\langle gn \mid f \rangle = (n \mid \det(Dg)f \circ g),$$

the infinitesimal action being $(un \mid f) = (n \mid \text{div}(fu))$. Take as before the simplest reduced Lagrangian

$$\ell(u,\nu) = \|u\|_g^2 + \frac{1}{\sigma^2} \|\nu\|_N^2.$$

We have, letting $f = (1/\sigma^2)K_H\nu$,

$$\left(\frac{\delta \ell}{\delta \nu} \circ n \right| u) = (f\nabla n \mid u)$$

and

$$(u \ast \frac{\delta \ell}{\delta \nu} \mid \omega) = (\omega \mid \text{div}(fu))$$

with the notation $(\nabla n \mid w) = -(n \mid \text{div}w)$. We therefore obtain the generalized version of (12):

$$\begin{cases}
    L_g u_t = -f_t \nabla n_t, \\
    \dot{f}_t + \text{div}(f_t u_t) = 0, \\
    \dot{n}_t - u_t n_t = \sigma^2 L_H f_t.
\end{cases} \quad (33)$$

As for measures, this leads to the integrated equations

$$\begin{cases}
    L_g u_t = -f_t \nabla n_t, \\
    n_t = g_t n_0 + \sigma^2 g_t \int_0^t g_s^{-1} L_H (f_0 \circ g_s^{-1} \det(g_s^{-1})) \, ds
\end{cases} \quad (34)$$

with $\dot{g}_t = u_t \circ g_t$.

In the 1D case, with $\rho = \sigma f$ and $m = L_g u = (1 - \partial_x^2)u$, we get a new version of (13):

$$\partial_t m + u \partial_x m + 2m \partial_x u = -\rho \partial_x L_H \rho \quad \text{with} \quad \partial_t \rho + \partial_x (\rho u) = 0. \quad (35)$$

11.2. Smooth image metamorphosis. We can go in the opposite direction and consider norms that will apply to smooth images in the metamorphosis formulation. Namely, keeping the notation of the previous section, we can define

$$\ell(u,\nu) = \|u\|_g^2 + \frac{1}{\sigma^2} \|\nu\|_H^2.$$
Since the situation is completely symmetrical, we can immediately write the new system, with \( f = (1/\sigma^2)L_H \nu \), as

\[
\begin{align*}
L_g u_t &= -f_t \nabla n_t, \\
\dot{f}_t + \text{div}(f_t u_t) &= 0, \\
\dot{n}_t - u_t n_t &= \sigma^2 K_H f_t.
\end{align*}
\] (36)

The second equation must be understood in a generalized sense, \( f \) being advected by the flow as a measure.

An interesting feature of this system is that it admits singular solutions for the pair \((L_g u, f)\). Indeed, assume that \( f_0 = \sum_{k=1}^{Q} w_{(k)} \delta_{x_0^{(k)}} \) is a sum of weighted point masses. The second equation in (36) implies that

\[
f_t = \sum_{k=1}^{Q} w_{(k)} \delta_{x_t^{(k)}}
\]

with \( x_t^{(k)} = u_t(x_t^{(k)}) \). We also have

\[
L_g u_t = \sum_{k=1}^{Q} a_t^{(k)} \otimes \delta_{x_t^{(k)}}
\]

with \( a_t^{(k)} = w^{(k)} \nabla n(x_t^{(k)}) \) and \( n \) evolves according to the last equation in the system.

Exploiting this very simple structure can lead to interesting new methods for the analysis of smooth (or smoothed) images and will be considered in future work. The 1D evolution equation associated to this context is (letting, again, \( \rho = \sigma f \))

\[
\partial_t m + u \partial_x m + 2m \partial_x u = -\rho \partial_x K_H \rho \quad \text{with} \quad \partial_t \rho + \partial_x (\rho u) = 0.
\] (37)

11.3. Smooth densities. Obviously, the same reduced Lagrangian can be used with densities. Using \( (\nabla f | u) = -(f | \text{div}(u)) \) as a definition of \( \nabla f \) for generalized functions, we get the system:

\[
\begin{align*}
L_g u_t &= -\nabla n_t f_t - n_t \nabla f_t, \\
\dot{f}_t + u_t^T \nabla f_t &= 0, \\
\dot{n}_t + \text{div}(u_t n_t) &= \sigma^2 K_H f_t.
\end{align*}
\] (38)

Here also, singular solutions in \((L_g u, f)\) exist, although (as seen from the first equation), \( L_g u \) is now one derivative less regular than \( f \).

12. Conclusion. We have provided a general framework for the pattern matching theory of metamorphoses. The equations provided are quite versatile and adapted to any context in which a Lie group acts on a manifold.

In the particular case of diffeomorphisms acting on generalized functions, we have obtained a new set of equations, and showed that they had solutions, and so does the initial variational problem. Our equations seem to indicate that, when matching measures,
metamorphoses do not generate additional singularities, but that they may introduce smooth components that did not appear in the initial problem.

Open for future work is the interesting problem of building an efficient numerical implementation of measure metamorphoses, and their use in specific pattern matching applications.
