CIRCULANT GRAPHS:
RECOGNIZING AND ISOMORPHISM TESTING
IN POLYNOMIAL TIME

S. A. EVDOKIMOV AND I. N. PONOMARENKO

Abstract. An algorithm is constructed for recognizing the circulant graphs and finding a canonical labeling for them in polynomial time. This algorithm also yields a cycle base of an arbitrary solvable permutation group. The consistency of the algorithm is based on a new result on the structure of Schur rings over a finite cyclic group.

§1. Introduction

A finite graph is said to be circulant if its automorphism group contains a full cycle, i.e., a permutation the cycle decomposition of which consists of a unique cycle of full length. This means that the graph admits a regular cyclic automorphism group, and, consequently, is isomorphic to a Cayley graph over a cyclic group. In particular, any circulant graph can be specified in a compact form by a full cycle automorphism and a neighborhood of some vertex.

One of the main computational problems concerning circulant graphs is that of finding an efficient algorithm to recognize them. (This problem is a special case of the following NP-complete problem: test whether or not a given graph has an automorphism without fixed points.) The first attempt to solve this problem was undertaken in [24], where a polynomial-time algorithm for recognizing circulant tournaments was described. In the subsequent papers [21, 22, 5] several results on recognizing some special classes of circulant graphs were presented, but the general problem remained open up to now. In the present paper we solve this problem completely. Another problem about circulant graphs is to find an efficient isomorphism test for them. In fact, this problem is polynomial-time reducible to the recognition problem, because two circulant graphs with the same number of vertices are isomorphic if and only if their disjoint union is a circulant graph. In this paper we present a solution to a more difficult problem of finding a canonical labeling for circulant graphs. It should be mentioned that the isomorphism problem for Cayley graphs over a cyclic group (which is a special case of the isomorphism problem for circulant graphs) has been extensively studied through the last forty years (see [20]). Most...
papers were aimed at finding efficient necessary and sufficient conditions for isomorphism of Cayley graphs over various special classes of cyclic groups.

The key notion of our approach is a cycle base of a finite permutation group $G$; by definition, this is any set of full cycles in $G$ with the property that any full cycle of $G$ is conjugate in $G$ to exactly one element of this set. Cycle bases were studied in [19] where it was proved that the cardinality of any cycle base of the group $G$ is at most $n$ (and even $\varphi(n)$, where $\varphi$ is the Euler function, modulo the classification of finite simple groups) where $n$ is the degree of $G$. A cycle base of a graph $\Gamma$ is defined to be a cycle base of its automorphism group $\text{Aut}(\Gamma)$. As will be shown below (see the proof of Theorem 1.1), the problems treated in this paper are reduced efficiently to the problem of finding a cycle base of its automorphism group $\text{Aut}(\Gamma)$. As will be shown below (see Theorem 1.2), the graphs $\mathbf{G}$ where $\mathbf{G}$ is the class of all graphs $\mathbf{C}$ over various special classes of cyclic groups. The following statement contains the main results of the paper. Though some parts of the proof are folklore, we present all the details in order to make the exposition self-contained.

**Theorem 1.1.** A cycle base of a graph on $n$ vertices can be found in time $n^{O(1)}$.

**Proof.** Let $\Gamma$ be a graph on $n$ vertices, and let $W$ be the smallest cellular ring containing the adjacency matrix of the graph $\Gamma$. It is easy to show that $\text{Aut}(\Gamma) = \text{Aut}(W)$ (see, e.g., [27]). From Theorem 7.1 it follows that a cycle base of the ring $W$ (i.e., of the group $\text{Aut}(W)$) can be found in time $n^{O(1)}$. Since the ring $W$ can be efficiently constructed by $\Gamma$ (see Theorem 8.2), we are done. \[\square\]

The following statement contains the main results of the paper. Though some parts of the proof are folklore, we present all the details in order to make the exposition self-contained.

**Theorem 1.2.** Let $\mathbf{G}$ (respectively, $\mathbf{C}$) be the class of all graphs (respectively, circulant graphs) on $n$ vertices. Then the following problems can be solved in time $n^{O(1)}$:

1. given a graph $\Gamma \in \mathbf{G}$, test whether $\Gamma \in \mathbf{C}$, and (if so) find a cycle automorphism of it;
2. given a graph $\Gamma \in \mathbf{C}$, find a canonical labeling of it;
3. given graphs $\Gamma, \Gamma' \in \mathbf{C}$, test whether $\Gamma \cong \Gamma'$, and (if so) find an isomorphism of them;
4. given a graph $\Gamma \in \mathbf{G}$, find a full system of pairwise nonequivalent Cayley representations of $\Gamma$ over a cyclic group of order $n$.

**Proof.** Obviously, a graph is circulant if and only if every cycle base of it is nonempty. Therefore, Problem (1) can be solved in time $n^{O(1)}$ by Theorem 1.1. Furthermore, Problem (3) is $O(n)$-reducible to Problem (2). We concentrate on Problems (2) and (4).

Let $V$ be a set of cardinality $n$. For any full cycle $c$ on $V$ and any element $v \in V$, there exists a unique bijection $f : V \rightarrow \{0, \ldots, n - 1\}$ taking $v^c$ to $i$ (then $c$ goes to the full cycle $(0, \ldots, n - 1)$). If $\Gamma$ is a graph on $V$ and $c \in \text{Aut}(\Gamma)$, then, obviously, the image $\Gamma^c$ of $\Gamma$ under $f$ does not depend on the choice of $v \in V$; we denote it by $\Gamma^c$. It is easily seen that for any two cycle automorphisms $c_1$ and $c_2$ of $\Gamma$ we have

\[(1) \quad \Gamma^{c_1} = \Gamma^{c_2} \iff c_1 \sim c_2,\]

where $c_1 \sim c_2$ means that $c_1$ and $c_2$ are conjugate in the group $\text{Aut}(\Gamma)$. Thus, the set $C(\Gamma) = \{\Gamma^c : c \in C\}$ does not depend on the choice of a cycle base $C$ of $\Gamma$. By Theorem 1.1, this set together with a set of isomorphisms $f : \Gamma \rightarrow \Gamma'$, $\Gamma' \in C(\Gamma)$ (one $f$ for each $\Gamma'$) can be found in time $n^{O(1)}$.

---

\[4\] By a Cayley representation of a graph $\Gamma$ over a group $G$ we mean a Cayley graph over $G$ isomorphic to $\Gamma$; two such representations are said to be equivalent if some isomorphism of the corresponding Cayley graphs belongs to $\text{Aut}(G)$ (see, e.g., [14]).
Now, let $\Gamma \in C_n$. Then $C(\Gamma) \neq \emptyset$. Moreover, from the previous paragraph it follows that the element $\Gamma'$ of $C(\Gamma)$ whose adjacency matrix is the lexicographical leader among the adjacency matrices of the graphs belonging to $C(\Gamma)$, can be found in time $n^{O(1)}$, together with the corresponding isomorphism $f$. The labeling $f$ of the graph $\Gamma$ is canonical (in the class $C_n$) because, obviously,

$$\Gamma_1 \cong \Gamma_2 \iff \Gamma_1^{f_1} = \Gamma_2^{f_2}$$

for all $\Gamma_1, \Gamma_2 \in C_n$, where $f_i$ is the labeling of $\Gamma_i$ ($i = 1, 2$). Thus, Problem (2) can be solved in time $n^{O(1)}$.

Finally, let $\Gamma \in G_n$. We treat the set $\{0, \ldots, n-1\}$ of the vertices of the graphs in $C(\Gamma)$ as the additive group $\mathbb{Z}_n^+$ of the ring $\mathbb{Z}_n = \mathbb{Z}/(n)$. It is easily seen that each graph in $C(\Gamma)$ is a Cayley representation of $\Gamma$ over this group. From (1) it follows that every Cayley representation of $\Gamma$ over $\mathbb{Z}_n^+$ is equivalent to at least one element of the set $C(\Gamma)$. On the other hand, two elements of $C(\Gamma)$ are equivalent if and only if there exists an isomorphism between them induced by multiplication by an element of the multiplicative group of the ring $\mathbb{Z}_n$. Since the set $C(\Gamma)$ can be found in time $n^{O(1)}$, this implies that Problem (4) can be solved within the same time.

As we saw in the proof of Theorem 1.1, the problem of finding a cycle base of a graph reduces to the problem of finding a cycle base of a cellular ring, i.e., a cycle base of its automorphism group. To approach the latter problem, we introduce the classes of quasinormal and singular cellular rings (see §§ 3 and 4) and prove that each Cayley ring over a cyclic group belongs to one of these classes (Theorem 5.1). We also show that both classes are efficiently recognizable. Moreover, the automorphism group of a quasinormal ring has a polynomial-time computable solvable subgroup containing all cycle automorphisms (Theorem 5.6), whereas a singular ring has a polynomial-time computable admissible extension (Theorem 4.4). (An extension of a cellular ring is said to be admissible if it is proper and each of its cycle bases contains a cycle base of the ring.) In a sense, a quasinormal ring can be thought of as a ring covered by normal Cayley rings over cyclic groups (see Definition 6.2). The latter rings were defined and studied in [11]; in fact, any such ring is the centralizer ring of a 2-closed subgroup of the holomorph of a cyclic group. On the other hand, each singular ring has a special subfactor of rank 2 (Definition 4.1); every automorphism of this subfactor can be lifted to an automorphism of the entire ring (Lemma 4.3). When passing to the corresponding admissible extension, we regularize the subfactor, thereby resolving the singularity. Now the algorithm of finding a cycle base of a cellular ring (Main Algorithm) can be outlined as follows (see §7 for the details).

1. While a current ring remains singular, replace it by an admissible extension.
2. If the current ring is not quasinormal, then the cycle base of the input ring is empty.
3. Find a solvable subgroup $G$ of the automorphism group of the current ring that contains all full cycle automorphisms.
4. Find a cycle base of $G$ and reduce it to a cycle base of the input ring.

Step 1 is performed by Algorithm A2 (43), which involves, in particular, the Weisfeiler–Leman algorithm (Subsection 8.3). Steps 2 and 3 are performed by Algorithm A1 (43). At the first stage of that algorithm we test whether or not the current ring is quasinormal, and if it is, we find a solvable group containing all cycle automorphisms of the current ring. At the second stage we apply the Babai–Luks algorithm to find the group $G$ in question as the intersection of the group mentioned in the preceding sentence and the automorphism group of the current ring. Finally, Step 4 is performed by Algorithm A3 (43). This algorithm allows us to efficiently find a cycle base of an arbitrary solvable
permutation group. The consistency of the Main Algorithm follows from Theorem 5.1 based on deep results on the structure of Schur rings over a cyclic group [11] [13].

All undefined terms and all results concerning permutation groups to be used in the sequel can be found in [28, 29, 4]. To make the paper self-contained, we collect the background material on cellular rings and Schur rings in §8.1. That section also contains some remarks on algorithms for such rings and for permutation groups.

Notation. As usual, we denote by \( \mathbb{Z} \) the ring of integers.

Throughout the paper, \( V \) denotes a finite set. For a (binary) relation \( R \) on \( V \) we set
\[
R^T = \{(u,v) \in V^2 : (v,u) \in R\} \quad \text{and} \quad R(u) = \{v \in V : (u,v) \in R\},
\]
where \( u \in V \).

By an equivalence on \( V \) we always mean a usual equivalence relation on \( V \); the set of all such equivalences is denoted by \( \mathcal{E}(V) \). If \( E \in \mathcal{E}(V) \), then the set of classes of \( E \) is denoted by \( V/E \), and for \( X \subset V \) we set \( X/E = X/(E \cap X^2) \). If \( E \) equals \( \Delta(V) = \{(v,v) : v \in V\} \), then the set \( X/E \) is identified with \( X \).

If \( R \) is a relation on \( V \), \( X \subset V \), and \( E \in \mathcal{E}(V) \), then we put
\[
R_{X/E} = \{(Y,Z) \in (X/E)^2 : (Y \times Z) \cap R \neq \emptyset\}
\]
and treat this set as a relation on \( X/E \).

The ring of all integral matrices with rows and columns indexed by the elements of \( V \) is denoted by \( \text{Mat}_V \), the identity matrix in \( \text{Mat}_V \) is \( I_V \), and the all-one matrix is \( J_V \).

The adjacency matrix of a relation \( R \) on \( V \) is denoted by \( A(R) \); this is a \( \{0,1\} \)-matrix in \( \text{Mat}_V \) such that its \( (u,v) \)-entry equals 1 if and only if \( (u,v) \in R \).

The group of all permutations of \( V \) is denoted by \( \text{Sym}(V) \). For \( S \subset \text{Sym}(V) \), we denote by \( \text{Cyc}(S) \) the set of all full cycles on \( V \) belonging to \( S \), and we set \( \text{Cyc}(V) = \text{Cyc}(\text{Sym}(V)) \).

Each bijection \( f : V \to V' \) \((v \mapsto v')\) naturally determines a bijection \( R \mapsto R' \) from the relations on \( V \) onto the relations on \( V' \). a ring isomorphism \( A \mapsto A' \) from \( \text{Mat}_V \) onto \( \text{Mat}_{V'} \), and a group isomorphism \( g \mapsto g' \) from \( \text{Sym}(V) \) onto \( \text{Sym}(V') \). For \( X \subset V \) and \( E \in \mathcal{E}(V) \), the bijection \( f \) induces a bijection \( f_{X/E} : X/E \to X'/E' \), where \( X' = f(X) \) and \( E' = f(E) \).

For a group \( G \), the permutation group on the set \( G \) defined by the left (respectively, right) multiplications is denoted by \( G_{\text{left}} \) (respectively, \( G_{\text{right}} \)).

For integers \( l, m \), the set \( \{l,l+1,\ldots,m\} \) is denoted by \([l,m]\). We write \([m]\) instead of \([1,m]\).

§2. Equivalences in homogeneous cellular rings

This section is of preliminary nature. The material presented here will be used throughout the paper. The relations \( R \) on \( V \) to be dealt with are assumed to have full support (i.e., \( R(v) \cup R^T(v) \neq \emptyset \) for all \( v \in V \)). Below we fix a homogeneous cellular ring \( W \leq \text{Mat}_V \), and we set \( \mathcal{R} = \mathcal{R}(W), \mathcal{R}^* = \mathcal{R}^*(W), \mathcal{E} = \mathcal{E}(W), \mathcal{B} = \mathcal{B}(W) \) (see Subsection §3.1).

2.1. Let \( R \) be a relation on \( V \). We denote by \( \mathcal{R}(R) \) the smallest equivalence on \( V \) containing \( R \) and call it the equivalence closure of \( R \):
\[
\mathcal{R}(R) = \bigcap_{E \in \mathcal{E}(V), E \supset R} E.
\]

It is easily seen that the classes of \( \mathcal{R}(R) \) are precisely the connected components of the graph on \( V \) with the edge set \( R \cup R^T \), so that \( \mathcal{R}(R) \) can be constructed efficiently. If \( E_1, E_2 \in \mathcal{E}(V) \), then, obviously, \( \mathcal{R}(E_1 \cup E_2) \) is the smallest equivalence on \( V \) the classes of
which are unions of classes of $E_1$ and $E_2$. A routine check shows that if $R \in \mathcal{R}^*$, then $(R) \in \mathcal{E}$. This implies that every $E \in \mathcal{E}\setminus \{\Delta(V)\}$ is of the form $E = (E_1 \cup R)$, where $E_1$ is a maximal element of the set $\{E' \in \mathcal{E} : E' \subset E, E' \neq E\}$ and $R \in \mathcal{R}$. Therefore, the elements of $\mathcal{E}$ can be listed in polynomial time in $|V|$ and $|\mathcal{E}|$.

Let $R$ be a relation on $V$. It is easily seen that the set of all equivalences $E \in \mathcal{E}(V)$ such that

$$ R = \bigcup_{(X,Y) \in R_{V/E}} X \times Y $$

is closed with respect to taking the equivalence closure of a union. Therefore, this set has the largest element. We call it the radical of $R$ and denote by $\text{rad}(R)$. Obviously, $\text{rad}(R) \subset (R)$. Furthermore,

$$ \text{rad}(R) = \text{Eq}(R) \cap \text{Eq}(R^T), $$

where for a relation $S$ on $V$ we set $\text{Eq}(S) = \{(u,v) \in V^2 : S(u) = S(v)\}$. Indeed, from the definition it follows that $\text{rad}(R) \subset \text{Eq}(R) \cap \text{Eq}(R^T)$. On the other hand, it is easy to show that the equivalence $E = \text{Eq}(R) \cap \text{Eq}(R^T)$ satisfies (2). Formula (3) implies that $\text{rad}(R)$ can be found in polynomial time in $|V|$. Now, if $R \in \mathcal{R}^*$, then $\text{Eq}(R), \text{Eq}(R^T) \in \mathcal{E}$ (see [6, p. 94]), so that $\text{rad}(R) \in \mathcal{E}$ by (3).

2.2. Let $E_1, E_2 \in \mathcal{E}(V)$ be such that

$$ E_1 \cap E_2 = \Delta(V), \quad (E_1 \cup E_2) = V^2. $$

The first condition enables us to define the mapping

$$ f : V \to V/E_1 \times V/E_2, \quad v \mapsto (X_1, X_2), $$

and, for $X_1 \in V/E_1$, the mapping

$$ t_{X_1} : X_1 \to V/E_2, \quad v \mapsto X_2, $$

where $X_i$ is the class of the equivalence $E_i$ containing $v$ ($i = 1, 2$ for (5)) and $i = 2$ for (6).

**Lemma 2.1.** The mappings $f$ and $t_{X_1}$ are bijections whenever the matrices $A(E_1)$ and $A(E_2)$ commute.

**Proof.** It suffices to prove the bijectivity of $f$. For this, we observe that the injectivity follows from the first relation in (4). On the other hand, the second relation implies that any two vertices of the graph on $V$ with the edge set $E_1 \cup E_2$ are connected by a path. If $A(E_1)A(E_2) = A(E_2)A(E_1)$, then, obviously, such a path can be chosen to be of length not exceeding 2. This means that $X_1 \cap X_2 \neq \emptyset$ for all $X_1 \in V/E_1$ and $X_2 \in V/E_2$, i.e., the mapping $f$ is surjective.\hfill $\Box$

The following theorem describes the properties of the mappings $f$ and $t_{X_1}$ in the case where $E_1, E_2 \in \mathcal{E}$.

**Theorem 2.2.** Suppose the ring $W$ is commutative, and let $E_1, E_2 \in \mathcal{E}$ be equivalences satisfying (4). Then the mappings $f$ and $t_{X_1}$ are bijections, and the following statements are true:

1) $W/ \geq W_{V/E_1} \otimes W_{V/E_2}$;

2) If $X_1 \in V/E_1$, then $t_{X_1} \in \text{Iso}(W_{X_1}, W_{V/E_2})$ and $(R_{X_1})^{t_{X_1}} = R_{V/E_2}$ for all $R \in \mathcal{R}$, $R \subset E_1$;

3) $t_{X_1}Y_1 \in \text{Iso}(W_{X_1}, W_{Y_1}, \varphi_{X_1,Y_1})$ for all $X_1, Y_1 \in V/E_1$, where $t_{X_1}Y_1 = t_{X_1} \circ t_{Y_1}$ and $\varphi_{X_1,Y_1}$ is the weak isomorphism described in Lemma 8.1.
Proof. The bijectivity of \( f \) and \( t_{X_1} \) follows from Lemma 2.1. We prove statement 1). A straightforward check shows that

\[
\left( \sum_{R \in \mathcal{R}, R_{V/E_2} = R_2} A(R) \right)^f = I_{V/E_1} \otimes A(R_2)
\]

for all \( R_2 \in \mathcal{R}(W_{V/E_2}) \). This implies that \( W_f \geq \{ I_{V/E_1} \} \otimes W_{V/E_2} \). Similarly, \( W_f \geq W_{V/E_1} \otimes \{ I_{V/E_2} \} \). Thus, statement 1) follows from these inclusions. Next, let \( R \in \mathcal{R}, R \subset E_1 \). Then, obviously, \( (R_{X_1})^{t_{X_1}} \subset R_{V/E_2} \). Therefore, it suffices to prove the first part of statement 2) only. Since the matrices \( A(E_1) \) and \( A(E_2) \) commute, we have

\[
R \cap (X_2 \times Y_2) = E_1 \cap (X_2 \times Y_2)
\]

for all \( X_2, Y_2 \in V/E_2 \) such that \( R \cap (X_2 \times Y_2) \neq \emptyset \). Thus, for each \( X_1 \in V/E_1 \) the bijection \( t_{X_1} \) induces a bijection \( \mathcal{R}(W_{X_1}) \rightarrow \mathcal{R}(W_{V/E_2}) \), whence \( t_{X_1} \in \text{Iso}(W_{X_1}, W_{V/E_2}) \). Finally, statement 3) follows from statement 2) and the definition of \( \varphi_{X,Y} \). \( \square \)

**Corollary 2.3.** Under the conditions of Theorem 2.2, suppose that \( G \leq \text{Aut}(W) \) is a regular Abelian group. Then the equivalences \( E_1 \) and \( E_2 \) are \( G \)-invariant, and

\[
G^f = G_{V/E_1} \times G_{V/E_2}, \quad (G_{X_1})^{t_{X_1}} = G_{V/E_2}
\]

for all \( X_1 \in V/E_1 \).

Proof. From statement 1) of Theorem 2.2 it follows that \( g^f = (g_{V/E_1}, g_{V/E_2}) \) for all \( g \in \text{Aut}(W) \). Therefore, \( G^f \leq G_{V/E_1} \times G_{V/E_2} \). On the other hand, since \( G \) is regular and Abelian, so are the groups \( G^f, G_{V/E_1}, \) and \( G_{V/E_2} \). This implies that

\[
|G^f| = |V^f| = |V/E_1| \cdot |V/E_2| = |G_{V/E_1}| \cdot |G_{V/E_2}| = |G_{V/E_1} \times G_{V/E_2}|,
\]

and the first relation follows. Since, obviously, \( (X_1, v^{t_{X_1}}) = v^f \) for all \( v \in X_1 \), the second relation is a consequence of the first. \( \square \)

2.3. Suppose \( E_0, E_1 \in \mathcal{E} \) and \( E_0 \subset E_1 \). We intend to compute the group \( \text{Aut}(W) \) in the case where \( W \) satisfies the \( E_1/E_0 \)-condition in the sense of the following definition (see also [3]).

**Definition 2.4.** We say that the ring \( W \) satisfies the \( E_1/E_0 \)-condition if \( E_0 \subset \text{rad}(R) \) for all \( R \in \mathcal{R} \) such that \( R \cap E_1 = \emptyset \).

Suppose we are given a permutation \( g_0 \in \text{Sym}(V/E_0) \) that respects the equivalence \( E_1 \) and, for each \( X \in V/E_1 \), a bijection \( g_X : X \rightarrow Y \), where \( Y \in V/E_1 \). The pair \( \{ g_X \}_{X \in V/E_1}, g_0 \) is said to be \( E_1/E_0 \)-admissible if \( g_X \mid X/E_0 = (g_0) \mid X/E_0 \) for all \( X \in V/E_1 \). In this case there exists a unique permutation of \( V \) equal to \( g_0 \) on \( V/E_0 \) and to \( g_X \) on any \( X \in V/E_1 \). We say that this permutation is induced by the pair \( \{ g_X \}_{X \in V/E_1}, g_0 \).

We say that an \( E_1/E_0 \)-admissible pair is compatible with \( W \) if the following conditions are satisfied:

(P1) \( g_X \in \text{Iso}(W_X, W_Y, \varphi_{X,Y}) \) for all \( X \in V/E_1 \);
(P2) \( g_0 \in \text{Aut}(W_{V/E_0}) \).

Let \( \mathcal{P}(W, E_1/E_0) \) denote the set of all permutations induced by \( E_1/E_0 \)-admissible pairs compatible with \( W \).

**Theorem 2.5.** Suppose the ring \( W \) satisfies the \( E_1/E_0 \)-condition for some \( E_0, E_1 \in \mathcal{E} \) such that \( E_0 \subset E_1 \). Then \( \text{Aut}(W) = \mathcal{P}(W, E_1/E_0) \).
Proof. The inclusion $\text{Aut}(W) \subset \mathcal{P}(W, E_1/E_0)$ is clear because any $g \in \text{Aut}(W)$ is induced by the pair $(\{gx\}_{x \in V/E_1}, g_{V/E_0})$, which is obviously compatible with $W$. Conversely, suppose that $g$ is induced by an $E_1/E_0$-admissible pair $(\{gx\}_{x \in V/E_1}, g_0)$ compatible with $W$. Then $R^g = R$ for all $R \in R$. Indeed, if $R \subset E_1$, then, by condition (P1),

$$R^g = \bigcup_{x \in V/E_1} (R_x)^{g_x} = \bigcup_{x \in V/E_1} (R_x)^{g_x, Y} = \bigcup_{x \in V/E_1} R_y = R,$$

where $Y = X^g$. Otherwise, we have $R \cap E_1 = \emptyset$, whence $E_0 \subset \text{rad}(R)$ by the conditions of the theorem (see Definition 2.4). Consequently, relation (2) and condition (P2) imply that

$$R^g = (\bigcup_{(x_0, y_0) \in R_0} X_0 \times Y_0)^g = \bigcup_{(x_0, y_0) \in R_0} (X_0)^g \times (Y_0)^g = \bigcup_{(x_0, y_0) \in R_0} X_0 \times Y_0 = \bigcup_{(x_0, y_0) \in R_0} X_0 \times Y_0 = R,$$

where $R_0 = R_{V/E_0}$.

§3. Quasinormal Cellular Rings

3.1. Let $W$ be a Cayley ring over a group $G$ (see Subsection 8.2). In accordance with [11], the ring $W$ is said to be normal if $G_{\text{right}}$ is a normal subgroup of $\text{Aut}(W)$. We denote by $\mathcal{W}_{\text{norm}}$, the class of all cellular rings strongly isomorphic to a normal Cayley ring over a cyclic group. It is easily seen that a cellular ring belongs to $\mathcal{W}_{\text{norm}}$ if and only if its automorphism group contains a normal regular cyclic subgroup. Any element of $\mathcal{W}_{\text{norm}}$ is called a normal ring (over a cyclic group). It can be proved that the automorphism group of a normal ring is isomorphic to a subgroup of the holomorph of a cyclic group (see [11] Theorem 4.5]). In particular, this automorphism group is solvable. Furthermore, from [11] Theorem 6.6] it follows that every weak isomorphism of normal rings is induced by a strong isomorphism. The following result allows us to handle normal rings efficiently (see also [3]).

Theorem 3.1. The following problems for cellular rings on $n$ points can be solved in time $n^{O(1)}$:

1. given a cellular ring $W$, test whether $W \in \mathcal{W}_{\text{norm}}$, and (if so) list all elements of the group $\text{Aut}(W)$;
2. given cellular rings $W, W' \in \mathcal{W}_{\text{norm}}$ and a weak isomorphism $\varphi : W \to W'$, list all elements of the set $\text{Iso}(W, W', \varphi)$.

Proof. First we recall that a cellular ring $W \leq \text{Mat}_V$ is said to be 1-regular if there exists a regular point, i.e., an element $v$ of $V$ such that $|R(v)| \leq 1$ for all $R \in \mathcal{R}(W)$ (see [11] §9). Next, obviously, if $\varphi : W \to W'$ is a weak isomorphism of cellular rings, then

$$R^\varphi (v^f) = R(v)^f, \quad f \in \text{Iso}(W, W', \varphi),$$

for every point $v$ of $W$. It follows that if $v$ is a fixed regular point of this ring, then any such isomorphism $f$ is uniquely determined (and can be constructed efficiently) by $v^f$. In particular, $|\text{Iso}(W, W', \varphi)| \leq n$, and the elements of this set can be listed in time $n^{O(1)}$.

Suppose $W \leq \text{Mat}_V$ is a cellular ring and $v \in V$. We set $W_v = [W, I_v]$, where $I_v = A((v, v))$ (see Subsection 8.1). If $\varphi : W \to W'$ is a weak isomorphism and $v' \in V'$, where $V'$ is the point set of $W'$, then, obviously, there exists at most one weak
isomorphism $\varphi_{v,v'} : W_v \to W'_v$, that coincides with $\varphi$ on $W$ and takes $I_v$ to $I'_v$. Moreover, it is easy to show that
\[
\text{Iso}(W, W', \varphi) = \bigcup_{v' \in S'} \text{Iso}(W_v, W'_v, \varphi_{v,v'}),
\]
where $S'$ is the set of all $v' \in V'$ such that the isomorphism $\varphi_{v,v'}$ does exist. Now, if $W, W' \in \mathcal{W}_\text{norm}$, then from [11] Theorem 6.1 it follows that the cellular rings $W_v$ and $W'_v$, are 1-regular for all $v \in V$ and $v' \in V'$. So, by the previous paragraph and Theorem [8, 3] Problem (2) can be solved in time $n^{O(1)}$. Since $\text{Aut}(W) = \text{Iso}(W, W; \text{id}_W)$, the same argument shows that the elements of this group can be listed efficiently whenever the ring $W_v$ is 1-regular for all $v \in V$. Since the latter condition is satisfied for any $W \in \mathcal{W}_\text{norm}$, we see that Problem (1) is $n^{O(1)}$-reducible to the recognition problem for 1-regular rings.

3.2. Let $W \leq \text{Mat}_V$ be a homogeneous cellular ring. Set
\[
\mathcal{F}(W) = \{ F = (E_0, E_1) : E_0, E_1 \in \mathcal{E}(W), \ E_0 \subset E_1\}.
\]
Any element $F$ of the set $\mathcal{F}(W)$ is called a flag of $W$ and will be denoted by $E_1/E_0$. From Lemma [8, 1] it follows that the cellular rings $W_{X/E_0}$, $X \in V/E_1$, are pairwise weakly isomorphic. Therefore, the numbers $|X/E_0|$ and $\text{rk}(W_{X/E_0})$ do not depend on the choice of $X \in V/E_1$; we denote them by $|F|$ and $\text{rk}(W_F)$, respectively. Moreover, all the rings $W_{X/E_0}$ are primitive or not simultaneously. In the former case we say that the flag $F$ is primitive. The flag $F$ is said to be normal if $W_{X/E_0}$ is a normal ring for all $X \in V/E_1$. We say that $F$ is a subflag of a flag $F' = E'_1/E'_0$ if $E_1 \subset E'_1$, $E_0 \supseteq E'_0$. In this case, obviously,
\[
\text{Aut}(W)_{X/E_0} \leq \text{Aut}(W_{X'/E'_0})_{X'/E'_0}
\]
for $X \in V/E_1$ and $X' \in V/E'_1$ with $X \subset X'$ (we identify $X/E_0$ with $(X/E'_0)/(E'_0)_{X/E_0}$).

Now suppose that the ring $W$ is commutative. Let $F = E_1/E_0$ and $F' = E_3/E_2$ be flags of $W$. We say that $F'$ is a multiple of $F$ if $E_0 = E_1 \cap E_2$ and $E_3 = (E_1 \cup E_2)$. In this case, if $G \leq \text{Aut}(W)$ is a regular cyclic group and $X \in V/E_3$, then, obviously, $G_{X/E_0}$ is a regular cyclic subgroup of $\text{Aut}(W_{X/E_0})$. Applying Corollary [2, 3] to the ring $W_{X/E_0}$ and the equivalences $(E_1)_{X/E_0}$ and $(E_2)_{X/E_0}$, we see that
\[
(G_{X_1/E_0})^{t_{X_1/E_0}} = G_{X_1/E_2}, \quad X_1 \in X/E_1,
\]
where $t_{X_1/E_0}$ is the bijection [3]. Denote by $\sim$ the equivalence closure of the relation “to be a multiple” on the set $\mathcal{F}(W)$. It can be checked that the set $\mathcal{E}(W)$ forms a modular lattice with respect to the operations of intersection and the equivalence closure of a union. Thus, the $\sim$-equivalence corresponds to the projectivity in a modular lattice [2].

**Definition 3.2.** A flag of a commutative cellular ring $W$ is said to be subnormal if it is a subflag of a normal flag of $W$; a flag is quasinormal if it is $\sim$-equivalent to a subnormal one. We say that the ring $W$ is quasinormal if every primitive flag of it is quasinormal.

Obviously, each normal cellular ring is quasinormal. The converse is not true. Indeed, let $W$ be the centralizer ring of the wreath product of two groups of prime order $p$. Obviously, the ring $W$ is not normal for $p \geq 3$. On the other hand, $W$ is quasinormal, because any primitive subfactor of it is strongly isomorphic to the centralizer ring of a regular group of order $p$, and, consequently, is normal. It can be proved that there exists a quasinormal ring such that not every primitive flag of it is subnormal.

Before stating the main result of the subsection, we need the following technical notion. Let $W \leq \text{Mat}_V$ be a homogeneous cellular ring. By a majorant of a group $G \leq \text{Aut}(W)$ with respect to a flag $E_1/E_0 \in \mathcal{F}(W)$ we mean a permutation group $G'$ on a set $V'$
together with a family of bijections $f_X : X/E_0 \to V'$ ($X \in V/E_1$) such that $(G_{X/E_0})^{f_X} \leq G'$. If $E_0 = \Delta(V)$ and $E_1 = V^2$, then we call $G'$ simply a majorant of $G$.

**Theorem 3.3.** If $W$ is a quasinormal cellular ring, then there exists a solvable majorant of the group $\text{Aut}_{\text{Cyc}}(W)$ generated by all cycle automorphisms of $W$. In particular, the group $\text{Aut}_{\text{Cyc}}(W)$ is solvable.

**Proof.** We deduce the theorem from the following two lemmas. Below for permutation groups $G_1, \ldots, G_s$, $s \geq 0$, we define a permutation group $\text{wr}(G_1, \ldots, G_s)$ as follows: this group is $\{1\}$ if $s = 0$; it coincides with $G_1$ if $s = 1$; with the wreath product of $G_1$ and $G_2$ (in imprimitive action) if $s = 2$; and with $\text{wr}(\text{wr}(G_1, \ldots, G_{s-1}), G_s)$ if $s \geq 3$.

**Lemma 3.4.** Suppose $W \leq \text{Mat}_V$ is a homogeneous cellular ring and $G \leq \text{Sym}(V)$. Let $E_0, \ldots, E_s \in \mathcal{E}(W)$ be equivalences satisfying the following conditions:

1) $\Delta(V) = E_0 \subset E_1 \subset \cdots \subset E_s = V^2$;
2) for each $i \in [s]$ we are given a majorant $(G_i, V_i, \{f_X\}_{X \in V/E_i})$ of the group $G$ with respect to the flag $E_i/E_{i-1}$.

Then the mapping

$$f : V \to \prod_{i=1}^{s} V_i, \quad v \mapsto (\ldots, f_{X_i}(X_{i-1}), \ldots),$$

is a bijection, where $X_i$ is the class of $E_i$ containing $v$, and $G^f \leq \text{wr}(G_1, \ldots, G_s)$.

**Proof.** It is easily seen that $f$ is a surjection. Thus, statement 1) follows from the relation $|V| = |E_s/E_0| = \prod_{i=1}^{s} |E_i/E_{i-1}|$. To prove the second statement, we assume (without loss of generality) that $s > 0$. Let $X \in V/E_{s-1}$. Then for every $i \in [s-1]$ the triple $(G_i, V_i, \{f_Y\}_{Y \in V/E_{i-1}})$ with $E_i \cap X = E_i \cap X^2$ is a majorant of the group $G_X \leq \text{Aut}(W_X)$ with respect to the flag $E_i/E_{i-1}, X \in \mathcal{F}(W_X)$. By induction, for the bijection $f_X : X \to \prod_{i=1}^{s} V_i$ we have

$$\begin{align*}
(G_X)^{f_X} & \leq \text{wr}(G_1, \ldots, G_{s-1}).
\end{align*}$$

On the other hand,

$$\begin{align*}
(G_{V/E_{s-1}})^{f_V} & \leq G_s
\end{align*}$$

(we have used the fact that $V/E_s = \{V\}$). Moreover, it is easy to check that $(G^f)_{X/E_0} = (G_X)^{f_X}$ for all $X \in V/E_{s-1}$, and $(G^f)_{V/E_{s-1}} = (G_{V/E_{s-1}})^{f_V}$ (we identify $V^f/(E_{s-1})^f$ with $V_s$). Thus, from (10) and (11) we deduce that $G^f \leq \text{wr}(G_1, \ldots, G_{s-1}), G_s) = \text{wr}(G_1, \ldots, G_s)$. □

**Lemma 3.5.** If $W$ is a quasinormal ring, then the group $\text{Aut}_{\text{Cyc}}(W)$ admits a solvable majorant with respect to any given primitive flag of $W$.

**Proof.** Let $F$ be a primitive flag of $W$. Then the quasinormality of $W$ implies that there exist flags $F_i = E_{i,1}/E_{i,0}$, $i \in [0, s]$, such that $F_0 = F$, the flag $F_s$ is subnormal, and for every $i \in [s]$ one of the flags $F_{i-1}$, $F_i$ is a multiple of the other. From (3) it follows that if $(G', V', \{f_X\}_{X \in V/E_{i-1}})$ is a majorant of the group $\text{Aut}_{\text{Cyc}}(W)$ with respect to $F_i$, then $(G', V', \{f_X\}_{X \in V/E_{i-1}, 1})$ is a majorant of the same group with respect to $F_{i-1}$, where $\overline{f}_{X} = \overline{f}_{X}/E_{i,0}$ if $F_{i-1}$ is a multiple of $F_i$ and $\overline{f}_{X} = t_{X/E_{i,0}}^{-1}$ otherwise. Thus, there is no loss of generality in assuming that the flag $F = E_1/E_0$ is subnormal, i.e., it is a subflag of a normal flag $F' = E_{i}'/E_0'$. For $X, Y \in V/E_1$, we denote by $X', Y'$ the classes of the equivalence $E_1'$ containing $X$ and $Y$ (respectively) and put $\overline{X} = X'/E_0'$, $\overline{Y}' = Y'/E_0'$. Since $W_{\overline{X}}, W_{\overline{Y}'} \in W_{unorm}$, there exists $f \in \text{Iso}(W_{\overline{X}}, W_{\overline{Y}'}, \varphi_{\overline{X}, \overline{Y}'})$ that takes
of flags in time \((\sim)\), one can test whether or not they are a connected graph can be found efficiently. Thus, given two primitive flags of \(\sim\), \(X/E_0\) and \(Y/E_0\) (see Subsection 3.1), we are done.

Returning to the proof of the theorem, we choose equivalences \(E_0,\ldots, E_s\) of \(W\) such that condition (1) of Lemma 3.3 is satisfied and the flag \(F_i = E_i/E_{i-1}\) is primitive for all \(i \in [s]\). By Lemma 3.5 for all \(i\) there exists a solvable majorant \((G_i, V_i, \{f_X\}_{X \in V/E_i})\) of the group \(\text{Aut}_{\text{Cyc}}(W)\) with respect to the flag \(F_i\). Set \(G' = \text{wr}(G_1,\ldots,G_s), V' = \prod_{i=1}^s V_i\). Then Lemma 3.4 shows that the triple \((G', V', \{f\})\), where \(f\) is the bijection (9), is a majorant of the group \(\text{Aut}_{\text{Cyc}}(W)\). Since the wreath product of solvable groups is solvable, we are done.

3.3. In this subsection we describe an algorithm for recognizing quasinormal cellular rings. Before doing this, we make some remarks concerning computations with flags.

Let \(W\) be a commutative cellular ring on \(n\) points. We denote by \(\Gamma\) the graph constructed on the set of all primitive flags of \(W\) and such that two vertices of \(\Gamma\) are adjacent if and only if one of the corresponding flags is a multiple of the other. Since the intersection of equivalences and the equivalence closure of their union can be found efficiently, it is not hard to test in time \(n^{O(1)}\) whether or not two given vertices of \(\Gamma\) are adjacent. Since the set \(E(W)\) can be found in time \((mn)^{O(1)}\), where \(m = |E(W)|\) (see Subsection 2.1), the graph \(\Gamma\) can be constructed within the same time. Moreover, two primitive flags are \(\sim\)-equivalent if and only if the corresponding vertices of \(\Gamma\) are joined by a path. It is well known that the connected components of a graph and a path joining any two vertices of a connected graph can be found efficiently. Thus, given two primitive flags of \(W\), we can test whether or not they are \(\sim\)-equivalent and (if they are) find an appropriate sequence of flags in time \((mn)^{O(1)}\).

Next, from statement 1) of Theorem 3.4 it follows that the normality of any flag of \(W\) can be tested in time \(n^{O(1)}\). Therefore, given a primitive flag of \(W\), we can test in time \(m^2n^{O(1)}\) whether it is subnormal by the exhaustive search over the set of all normal flags of \(W\). This enables us to efficiently recognize the primitive quasinormal flags. Finally, from the proof of Lemma 3.3 and Theorem 3.1 it follows that a solvable majorant of the group \(\text{Aut}_{\text{Cyc}}(W)\) with respect to any given primitive quasinormal flag of \(W\) can be found in time \((mn)^{O(1)}\).

Algorithm A1.

Input: a cellular ring \(W \leq \text{Mat}_V\).

Output: a solvable group \(G\) such that \(\text{Aut}_{\text{Cyc}}(W) \leq G \leq \text{Aut}(W)\) if \(W\) is a quasinormal ring, or \(G = \emptyset\) otherwise.

Step 1. If \(W\) is not commutative, then the output \(G\) is empty. Otherwise construct the graph \(\Gamma\) on the set of all primitive flags of \(W\) (see above) and the set \(\mathcal{F}\) of all subnormal flags of \(W\).

Step 2. If none of the vertices of some connected component of \(\Gamma\) belongs to \(\mathcal{F}\), then the output \(G\) is empty. Otherwise choose a maximal path \(\Delta(V) = E_0 \subseteq E_1 \subseteq \cdots \subseteq E_s = V^2\) of equivalences of \(W\).

Step 3. Find a solvable majorant \((G_i, V_i, \{f_X\}_{X \in V/E_i})\) of the group \(\text{Aut}_{\text{cyc}}(W)\) relative to the flag \(E_i/E_{i-1}\), \(i \in [s]\) (see above), the group \(G' = \text{wr}(G_1,\ldots,G_s)\), and the bijection \(f\) defined by (9).
Step 4. The output group $G = \text{Aut}(W) \cap (G')^{-1}$ is found by the Babai–Luks algorithm (see Theorem 3.6).

**Theorem 3.6.** Algorithm A1 tests the quasinormality of the ring $W$ in time $(mn)^{O(1)}$, where $m = |E(W)|$ and $n = |V|$. Moreover, if $W$ is quasinormal, then it finds a solvable group $G$ such that $\text{Aut}_{\text{cycle}}(W) \leq G \leq \text{Aut}(W)$ within the same time.

**Proof.** From the definitions of a quasinormal ring and the graph $\Gamma$ it follows that $W$ is not a quasinormal ring if and only if the algorithm terminates before Step 3. This implies that the algorithm always finds a cycle automorphism group $G'$ defined at Step 3 is solvable because it is a wreath product of solvable groups. Thus, the consistency of the algorithm follows from Lemma 3.4 (which implies that $\text{Aut}_{\text{cycle}}(W) \leq G'$), and from the consistency of the Babai–Luks algorithm. The required time bound follows from Theorem 3.6 and the remarks before the algorithm. □

§4. Singular rings

4.1. As will be shown below (see Theorem 5.1), every cellular ring admitting a cycle automorphism is quasinormal or has a singularity in the following sense.

Let $W \leq \text{Mat}_V$ be a commutative cellular ring, and let $F = E_1/E_0$ and $F' = E_3/E_2$ be flags of $W$. Suppose that $F'$ is a multiple of $F$ and the following conditions are satisfied (see Subsection 2.3):

(S1) $W$ satisfies both the $E_2/E_0$-condition and the $E_3/E_1$-condition;
(S2) $W_{X/E_0} = W_{X/E_1} \otimes W_{X/E_2}$ for all $X \in V/E_3$.

(The set $X/E_0$ is identified with $X/E_1 \times X/E_2$ with the help of the bijection in Lemma 2.4 applied to $V = X/E_0$.) We observe that $\text{rk}(W_F) = \text{rk}(W_{F'})$ by statement 2) of Theorem 2.2.

**Definition 4.1.** We say that the ring $W$ has a singularity in the pair $(F, F')$ if $\text{rk}(W_F) = 2$. In this case the number $d = |F| = |F'|$ is called the singularity degree. The ring $W$ is said to be singular if it has singularity of degree $d \geq 3$ in some pair $(F, F')$.

We shall resolve the singularity by replacing $W$ with the smallest cellular ring $W' = [W, A]$ that contains $W$, $A$ being the adjacency matrix of a relation of the form

$$R(\tilde{\mathcal{F}}) = \bigcup_{X \in V/E_1} \bigcup_{Y \in X/E_2} Y \times Y^f_X,$$

where $\tilde{\mathcal{F}} = \{f_X\}_{X \in V/E_1}$ with $f_X \in \text{Cyc}(X/E_2)$. The next theorem shows that in this case we can control the cycle bases of the rings $W$ and $W'$. As in 19, we say that a subgroup $G'$ of a permutation group $G$ is well embedded if every cycle base of $G'$ contains a cycle base of $G$, or, equivalently, if every full cycle of $G$ is conjugate in $G$ to some full cycle of $G'$.

**Theorem 4.2.** In the above notation, for any family $\tilde{\mathcal{F}}$ the group $\text{Aut}(W')$ is a well-embedded subgroup of $\text{Aut}(W)$.

**Proof.** Let $\tilde{\mathcal{F}} = \{f_X\}_{X \in V/E_1}$, where $f_X \in \text{Cyc}(X/E_2)$. Since $W' \geq W$, without loss of generality we may assume that $\text{Cyc}(\text{Aut}(W)) \neq \emptyset$. Let $g$ be a cycle automorphism of $W$. Then $(E_3)^g = E_3$, so that $X^{g^k} = X$ for all $X \in V/E_3$, where $k = |V/E_3|$. It is easily seen that $g_X = (g^k)^{X/E_2}$ is a full cycle on $X/E_2$. Therefore, we can find a permutation $h_X \in \text{Sym}(X/E_2)$ such that $f_X = h_X^{-1}g_Xh_X$. Suppose for a while that there exists $h^* \in \text{Aut}(W)$ such that

$$h^*_{X/E_2} = h_X, \quad X \in V/E_3.$$
Then, obviously, the permutation \( g' = (h^*)^{-1}gh^* \) belongs to \( \text{Cyc}(\text{Aut}(W)) \). Consequently, for \( X \in V/E_3 \) and \( Y \in X/E_2 \), we have
\[
(Yfx)^g' = (Yfx)(h^*)^{-1}gh^* = (Yfxh^{-1}x)x)gh^* = (Yhx^{-1}x)gh^* = (Yhx^{-1})h^*f_{xy} = (Yhx^{-1}g(\tilde{X})h^*)f_{xy}
\]
whence
\[
R^g' = \bigcup_{x \in V/E_3} Y^g' \times (Yfx)^g' = \bigcup_{x \in V/E_3} Y^g' \times (Yfx)^g = R,
\]
where \( R = R(\tilde{X}) \). Thus, \( g' \in \text{Cyc}(\text{Aut}(W')) \). Since \( g \) is conjugate in \( \text{Aut}(W) \) to \( g' \), we are done.

Now we prove the existence of \( h^* \in \text{Aut}(W) \) satisfying (13). For this, we observe that the permutation \( g' \) with \( l = [V/E_1] \) induces the identical permutation of \( X/E_3 \) and a full cycle of \( X/E_2 \). This implies that for each \( Y \in X/E_2 \) there exists a power of this permutation that takes \( Y \) to \( Y' = Yh^x \). Obviously, the induced bijection \( h_Y : Y \rightarrow Y' \) satisfies the following conditions:
\[
h_Y \in \text{Iso}(W_Y, W_{Y'}, \varphi_{Y,Y'}), \quad (h_Y)_Y/E_0 = t_Y/E_0, Y'/E_0,
\]
where \( \varphi_{Y,Y'} \) is the weak isomorphism described in Lemma 8.1 and \( t_Y/E_0, Y'/E_0 \) is the bijection defined in statement 3 of Theorem 2.2. Thus, the required statement follows from the next lemma.

**Lemma 4.3.** In the notation of the theorem, suppose that for every \( X \in V/E_3 \) we are given a permutation \( h_X \in \text{Sym}(X/E_2) \) and for every \( Y \in X/E_2 \), a bijection \( h_Y : Y \rightarrow Y' \) satisfying (14), where \( Y' = Yh^x \). Then there exists a unique \( h^* \in \text{Aut}(W) \) such that \( (h^*)_X/e_2 = h_X, (h^*)_Y/e_1 = 1d_X/e_1 \), and \( (h^*)_Y = h_Y \) for all \( X \) and \( Y \).

**Proof.** The uniqueness of \( h^* \) follows from the third condition imposed on it. To prove the existence, we take \( X \in V/E_3 \) and denote by \( h_X \) the permutation of the set \( X/E_0 = X/E_1 \times X/E_2 \) taking \((X_1, X_2)\) to \((X_1, X_2)h^X_\). Then the pair \( \{h_Y, h_X\} \) is \( (E_2/E_0)_X \)-admissible, where \( (E_2/E_0)_X = (E_2/X)/(E_0/X) \) (see Subsection 2.3) because \( (h_Y)_Y/E_0 = t_Y/E_0, Y'/E_0 \). Moreover, it is compatible with the ring \( W_X \). Indeed, condition (P1) is satisfied by assumption. Next, since \( \text{rk}(W_X/E_2) = 2 \), condition (S2) implies that \( h_X \in \text{Aut}(W_X/E_0) \). Thus, condition (P2) is also satisfied.

Now, we set \( h'_X \) to be the permutation of \( X \) induced by the pair \( \{h_Y, h_X\} \). Then \( h'_X \in P(W_X, (E_2/E_0)_X) \). On the other hand, condition (S1) implies that the ring \( W_X \) satisfies the \( (E_2/E_0)_X \)-condition. Then \( h'_X \in \text{Aut}(W_X) \) by Theorem 2.5. Moreover, since \( (h'_X)_X/E_1 = h_X \), we have \( (h'_X)_X/E_1 = 1d_X/E_1 \). Thus, the pair \( \{h'_X, 1d_Y/E_1\} \) is \( E_3/E_1 \)-admissible and, therefore, compatible with \( W \). Moreover, the ring \( W \) satisfies the \( E_3/E_1 \)-condition (see (S1)). By Theorem 2.5 the permutation \( h^* \) of \( V \) induced by this pair belongs to \( \text{Aut}(W) \). Since \( (h^*)_X = h'_X \) for all \( X \in V/E_3 \), we have done. \( \square \)

4.2. Below we present an efficient algorithm for recognizing singular rings and for resolving their singularities. We start with some preliminary remarks. Let \( F = E_1/E_0 \) and \( F' = E_3/E_2 \) be flags of a commutative cellular ring \( W \leq \text{Mat}_V \). First, since the equivalences \( E_1 \cap E_2 \) and \( (E_1 \cup E_2) \) can easily be constructed (see Subsection 2.7), we can test efficiently whether or not \( F' \) is a multiple of \( F \). Next, since the radical of any relation can easily be found, the \( E_2/E_0 \)-condition and the \( E_3/E_2 \)-condition for \( W \) can be tested efficiently. Finally, for a given \( X \in V/E_3 \), the identity in (S2) can also be tested efficiently (e.g., by comparing the basis relations). Thus, the presence of singularity for
W in the pair \((F,F')\) can be tested in time \(n^{O(1)}\), where \(n = |V|\). We say that an extension \(W'\) of \(W\) is *admissible* if \(\text{Aut}(W')\) is a well-embedded subgroup of \(\text{Aut}(W)\) and \(W' \neq W\).

**Algorithm A2.**  
**Input:** a cellular ring \(W \leq \text{Mat}_V\).  
**Output:** an admissible extension \(W'\) of \(W\) if \(W\) is singular or \(W' = \emptyset\) otherwise.

1. **Step 1.** If \(W\) is not commutative, then the output \(W'\) is empty. Otherwise construct the set \(\mathcal{E}(W)\) (see Subsection 2.1) and then the set \(\mathcal{F}(W)\).
2. **Step 2.** Find the set \(\mathcal{P}\) of all pairs \((F,F') \in \mathcal{F}(W)^2\) such that \(W\) has singularity of degree at least 3 in \((F,F')\) (see above).
3. **Step 3.** If \(\mathcal{P} = \emptyset\), then the output \(W'\) is empty. Otherwise choose \((F,F') \in \mathcal{P}\).
4. **Step 4.** Take \(W' = [W,A]\) as the output, where \(A\) is the adjacency matrix of relation \((12)\) with a family \(\mathfrak{F}\) chosen arbitrarily.

Theorem 4.4. Algorithm A2 tests the singularity of the ring \(W\) in time \((mn)^{O(1)}\), where \(m = |\mathcal{E}(W)|\) and \(n = |V|\). Moreover, if \(W\) is singular, then it finds an admissible extension \(W'\) of \(W\) within the same time.

Proof. The consistency of the algorithm is a consequence of Theorem 4.2, the definition of a singular ring, and the fact that at Step 4 we have \(W' \neq W\) because \(W\) has singularity of degree at least 3 in \((F,F')\). Since the set \(\mathcal{E}(W)\) can be constructed in time \((mn)^{O(1)}\) (see Subsection 2.1), the required time bound follows from Theorem 8.3 and the remarks before the algorithm.

In this paper, Algorithm A2 will be applied only in the case where \(m \leq n\), so that in this case its complexity is bounded by \(n^{O(1)}\). In the general case, this algorithm can be modified so as to achieve the same time upper bound. Indeed, it can be proved that if \(W\) has singularity in \((F,F')\), then \(E_1 \setminus E_0 \in \mathcal{R}(W)\) and \(E_2\) coincides with the equivalence closure of the union of all \(R \in \mathcal{R}(W)\) such that \(\langle R \rangle \cap E_1 \subseteq E_0\).

§5. **Quasinormal and singular Cayley rings over a cyclic group**

In this section we deal with quasinormal and singular rings (see §4.3 and 4) that are Cayley rings over a cyclic group. The main result can be formulated as follows.

**Theorem 5.1.** Every cellular ring admitting a full cycle automorphism is either quasinormal or singular.

Proof. Let \(W\) be a cellular ring such that \(\text{Cyc}(\text{Aut}(W)) \neq \emptyset\). Without loss of generality we may assume that \(W\) is a Cayley ring over a cyclic group \(G\) (see Subsection 8.2). We observe that, by Theorem 8.3, the lattice \(\mathcal{E} = \mathcal{E}(W)\) of equivalences of \(W\) is isomorphic to a sublattice of the lattice of subgroups of the group \(G\), which, by the cyclicity of \(G\), is isomorphic to the lattice of divisors of the integer \(n = |G|\). In accordance with [2], the latter lattice is distributive; consequently, so is the lattice \(\mathcal{E}\). Let \(\mathcal{C}\) be a class of \(\sim\)-equivalence on the set of all flags of the ring \(W\). We say that an element of \(\mathcal{C}\) is a *smallest* (respectively, a *greatest*) one if every element of this class is a multiple of it (respectively, it is a multiple of every element of this class).

**Lemma 5.2.** Each class of the \(\sim\)-equivalence on the set \(\mathcal{F}(W)\) of all flags of \(W\) contains a smallest element and a greatest element.

\[\text{In what follows, for } E_1, E_2 \in \mathcal{E} \text{ we write } E_1E_2 \text{ instead of } (E_1 \cup E_2).\]
Proof. Since the notion of $\sim$-equivalence is self-dual, we only verify the existence of a smallest element. The transitivity of the relation “to be a multiple” and the definition of the $\sim$-equivalence show that it suffices to prove that if $F_i$ is a multiple of both $F_1$ and $F_2$, then there exists $F_0$ such that both $F_1$ and $F_2$ are multiples of $F_0$ (here $F_i \in F(W)$ for all $i$). Let $F_i = E_{i1}/E_{i0}$ ($i = 1, 2, 3$). We set $F_0 = E_{01}/E_{00}$, where $E_{0j} = E_{1j} \cap E_{2j}$ ($j = 1, 2$). Then

$$E_{00} = E_{01} \cap E_{00} = E_{01} \cap E_{i0} \cap E_{0i'} = (E_{01} \cap E_{i0}) \cap (E_{i1} \cap E_{30}) = E_{01} \cap E_{i0}$$

and, by the distributivity of the lattice $E$,

$$E_{i1} = E_{31} \cap E_{i1} = (E_{i1} \cap E_{30}) \cap E_{i1} = (E_{i1} \cap E_{11})(E_{30} \cap E_{11}) = E_{01}E_{i0},$$

where $i' = 3 - i$ ($i = 1, 2$). Thus, both $F_1$ and $F_2$ are multiples of $F_0$. \hfill $\Box$

Suppose that the ring $W$ is not quasinormal. There exists a class $C$ of the $\sim$-equivalence on the set of all primitive flags of $W$ such that $C$ contains no subnormal flags. Let $F = E_1/E_0$ and $F' = E_3/E_2$ be a smallest and a greatest elements of $C$. Theorem 5.1 is a consequence of the proposition below.

Proposition 5.3. The ring $W$ has singularity of degree $d \geq 4$ in the pair $(F, F')$.

Proof. First, we observe that $d = |F| = |F'| \geq 4$, because otherwise the flags $F$ and $F'$ must be normal. Next, it is easily seen that for all $X \in G/E_0$ the ring $W_{X/E_0}$ is strongly isomorphic to a Cayley ring over a cyclic group. Since this ring is primitive, Theorem 2.10.5 in [3] implies that either its rank equals 2, or its degree is a prime. In the latter case the rank also equals 2, because otherwise the ring $W_{X/E_0}$ is normal by [3] Theorem 12.7.5. Thus, it suffices to verify conditions (S1) and (S2).

We set $A = W^{\rho^{-1}}$ and $H_i = (E_i)^{\rho^{-1}}$, $i = 0, 1, 2, 3$, where $\rho = \rho_0$ is the monomorphism (22). Then $A$ is an S-ring over the group $G$, $H_i \in \mathcal{H}(A)$ for all $i$, and $H_0 = H_1 \cap H_2$, $H_3 = H_1H_2$ (here and below we freely use the notation and the facts of Subsection 5.2). Since, obviously, rad($R$) = rad($X$)$^\rho$ for all $R \in R^*$($W$), where $X = R^{\rho^{-1}}$, the cellular ring $W$ satisfies the $E_{i+2}/E_i$-condition if and only if the S-ring $A$ satisfies the $H_{i+2}/H_i$-condition ($i = 0, 1$). Furthermore, the correspondence between the Cayley rings and the S-rings respects the tensor product. Thus it suffices to check the following:

(S1') $A$ satisfies both the $H_2/H_0$-condition and the $H_3/H_1$-condition;
(S2') $A_{H_5/H_0} = A_{H_1/H_0} \otimes A_{H_2/H_0}$.

For this, let $X \in S(A)$. Then it suffices to verify that rad($X$) $\geq H_i$ whenever $X \subset G \setminus H_{i+2}$, $i = 0, 1$ (condition (S1')), and that $XH_0 = X_1H_0 \cdot X_2H_0$ for some $X_i \in S(A_{H_i})$, $i = 1, 2$, whenever $X \subset H_3$ (condition (S2')). We shall check both conditions simultaneously. First, suppose that $X \subset H_2$ or rad($X$) $\geq H_3$. Then in condition (S1') there is nothing to check. Next, condition (S2') is satisfied trivially for $X \subset H_2$. If rad($X$) $\geq H_1$, then $X \not\subset H_3$, for otherwise the image of the basic set $X$ under the natural epimorphism $H_3 \rightarrow H_1/H_0$ would be equal to $H_1/H_0$, which is not a basic set of the ring $A_{H_1/H_0}$. So, in this case condition (S2') is also satisfied. Thus, without loss of generality we may assume that

\begin{equation}
X \not\subset H_2, \quad \text{rad}(X) \not\geq H_3.
\end{equation}

Then the required conditions are satisfied by the following lemma.

Lemma 5.4. In the above notation and under the above assumptions, we have $H_0 \leq \text{rad}(X)$ and $\langle X \rangle \subset H_3$. Moreover, $X = X_1X_2$, where $X_1 = H_1 \setminus H_0$ and $X_2 \in S^*(A_{H_2})$ with $X_2H_0 = X_2$. 

Proof. Using the results of Subsection 8.2, we transfer the notions of a flag, subflag, multiple, and \( \sim \)-equivalence, and also of normality, subnormality, and quasinormality of a flag, from the Cayley rings to the S-rings. We observe that a flag \( U/L \) of the S-ring \( \mathcal{A} \) is normal if and only if the S-ring \( \mathcal{A}_{U/L} \) is normal in the sense of \([11]\) (i.e., the cellular ring \( (\mathcal{A}_{U/L})^{U/L} \) is normal). Moreover, from the definition of \( H_i \) (\( i = 0, 1, 2, 3 \)) it follows that the flag \( H_3/H_2 \) is a multiple of \( H_1/H_0 \), and that no flag in the class of the \( \sim \)-equivalence containing both of them is subnormal. Moreover, the flags \( H_1/H_0 \) and \( H_3/H_2 \) are the smallest and the greatest element of this class, respectively. Putting \( U = \langle X \rangle \) and \( L = \text{rad}(X) \), we show that

\[
(16) \quad H_1/H_0 \sim H_1L/H_0L, \quad H_3/H_2 \sim (H_3 \cap U)/(H_2 \cap U).
\]

Since the proofs of both equivalences are similar, we prove the second for instance. We start with the observation that the flag \( H_3U/H_3U \) is not a multiple of \( H_3/H_2 \). (Otherwise, \( U \leq H_3 \) because the latter flag is maximal. Since also \( H_3 \cap H_2U = H_2 \), we have \( H_3U = H_2 \), which contradicts the first relation in \((15)\).) Therefore, \( H_2 < H_3 \cap (H_3U) \), whence \( H_3 \cap (H_2U) = H_3 \) because \( \text{rk}(\mathcal{A}_{H_3/H_2}) = 2 \). Thus, \( H_3 \leq H_2U \), and we obtain

\[
H_0(H_1 \cap U) = (H_1 \cap H_2)(H_1 \cap U) = H_1 \cap (H_2U) = H_1
\]

by the distributivity of the lattice \( \mathcal{H}(\mathcal{A}) \). This implies that \( H_1/H_0 \) is a multiple of \((H_1 \cap U)/(H_0 \cap U)\), so that \( H_1 \leq U \) by the minimality of the flag \( H_1/H_0 \). It follows that \( H_3 \geq (H_3 \cap U)H_2 \geq H_1H_2 = H_3 \), and, consequently, \((H_3 \cap U)H_2 = H_3 \). Obviously, since \((H_3 \cap U) \cap H_2 = H_2 \cap U \), this implies that \( H_3/H_2 \) is a multiple of \((H_3 \cap U)/(H_2 \cap U)\).

From \((16)\) and the fact that \( H_1/H_0 \) and \( H_3/H_2 \) are the smallest and the greatest element, respectively, it follows that the flags \( H_1L/H_0L \) and \((H_3 \cap U)/(H_2 \cap U) \) are subflags of \( U/L \). We prove that there exist groups \( H, H' \in \mathcal{H}(\mathcal{A}) \) such that \( L \leq H, H' \leq U \) and

\[
(17) \quad H_1L/H_0L \sim H/L, \quad (H_3 \cap U)/(H_2 \cap U) \sim U/H', \quad \mathcal{A}_{U/L} = \mathcal{A}_{H/L} \otimes \mathcal{A}_{H'/L}.
\]

For this, we observe that the radical of the image of \( X \) in \( U/L \) is trivial. Then from \([17\) Theorem 3.1] and the definition of \( U \) it follows that this image contains a generator of the group \( U/L \). So, the S-ring \( \mathcal{A}_{U/L} \) has a trivial radical in the sense of \([11\). By \([11\ Corollary 6.4\), this implies the existence of groups \( U_i \in \mathcal{H}(\mathcal{A}) \), \( L \leq U_i \leq U \) (\( i = 0, \ldots, s \)), such that

\[
(18) \quad \mathcal{A}_{U_i/L} = \bigotimes_{i=0}^{s} \mathcal{A}_{U_i/L},
\]

where \( \mathcal{A}_{U_0/L} \) is a normal \( S \)-ring and \( \text{rk}(\mathcal{A}_{U_i/L}) = 2 \) for all \( i > 0 \). It is easily seen that every group belonging to \( \mathcal{H}(\mathcal{A}_{U/L}) \) is of the form \( \prod_{i=0}^{s} U_i/L \), where \( U'_0 \in \mathcal{H}(\mathcal{A}) \), \( L \leq U'_i \leq U_0 \), and \( U'_i \in \{U_i, L\} \) for \( i > 0 \). Therefore, every subflag \( F \) of \( U/L \) with \( \text{rk}(\mathcal{A}_F) = 2 \) is \( \sim \)-equivalent either to a subflag of \( U_0/L \) or to both flags \( U_i/L \) and \( U'/i \) for some \( i > 0 \), where \( U'_i \) is the product of the \( U_j \) with \( j \neq i \). On the other hand, the flags \( H_1L/H_0L \) and \((H_3 \cap U)/(H_2 \cap U) \) are not quasinormal because the flags \( H_1/H_0 \) and \( H_3/H_2 \) are not quasinormal (see \((16)\)). Thus, by the normality of the ring \( \mathcal{A}_{U_0/L} \), the first case is impossible for the former two flags. We conclude that there exists \( i > 0 \) such that \( H_1L/H_0L \sim U_i/L \) and \((H_3 \cap U)/(H_2 \cap U) \sim U_i/H' \). Therefore, \((17)\) is true for \( H = U_i \) and \( H' = U'_i \) (see \((15)\)).

To complete the proof of the lemma, we observe that the first part of it follows from the equivalences \((16)\) and \((17)\), because the flags \( H_1/H_0 \) and \( H_3/H_2 \) are (respectively) the smallest and the greatest element of the \( \sim \)-equivalence class containing both of them. Next, \((17)\) implies that \( X = X_1X_2 \) for some \( X_1 \in S^*(\mathcal{A}_H) \) and \( X_2 \in S^*(\mathcal{A}_{H'}) \) such that
$X_i = X_iL$ ($i = 1, 2$). Thus, the second part of the lemma is a consequence of the first part and the relation $X_1 = (H_1 \setminus H_0)L$. \hfill \qed

## 66. Cycle base of a solvable group

### 6.1. In this section we construct a polynomial-time algorithm for finding a cycle base of an arbitrary solvable permutation group. First, we treat a slightly different problem.

Let $G \leq \text{Sym}(V)$ be a permutation group, and let $c \in \text{Sym}(V)$ normalize $G$. Suppose that $V_0, \ldots, V_{m-1}$ are pairwise disjoint subsets of $V$ such that

\begin{equation}
V = \bigcup_{i=0}^{m-1} V_i, \quad \text{where } (V_i)^G = V_i, (V_i)^c = V_{i+1} \text{ for all } i
\end{equation}

(19) (here and below, addition of indices is meant modulo $m$). We denote by $G_i$ the permutation group induced by the action of $G$ on $V_i$. Then, since $G^c = c^{-1}Gc = G$, from (19) it follows that $(G_i)^c = G_{i+1}$ for all $i$ (for brevity, we write $c$ instead of $cV_i$). Given $X \subseteq G$ and $S \subseteq [0, m-1]$, we set $X_S = \varphi_S(X)$, where

$$
\varphi_S : G \rightarrow \prod_{i \in S} G_i, \quad g \mapsto (\ldots, g_i, \ldots),
$$

is the homomorphism induced by the natural epimorphisms $G \rightarrow G_i$ ($i \in S$). If $S = \{i\}$, we write $X_i$ and $\varphi_i$ instead of $X_S$ and $\varphi_S$, respectively. Obviously, $\varphi_S$ is a monomorphism for $S = [0, m-1]$. Concerning computation with permutation groups in the algorithm below, see Subsection 8.3.

**Algorithm A3'.**

**Input:** a group $G \leq \text{Sym}(V)$ and a permutation $c \in \text{Sym}(V)$ as above.

**Output:** a set $X \subseteq Gc$ (given as a list of elements) such that $Gc = \bigcup_{g \in G} X^g$.

**Step 1.** If $G = \{1\}$, then the output $X$ is equal to $\{c\}$. Otherwise, use the normal closure algorithm to find a maximal $c^m$-invariant normal subgroup $K_0$ of $G_0$.

**Step 2.** Set $G^{(0)} = G$. For $i = 0, \ldots, m - 1$ successively, use the sift procedure to find the group $G^{(i+1)} = G^{(i)} \cap \varphi_{i+1}^{-1}(K_i)$, where $K_i = (K_0)^c$.

**Step 3.** By the sift procedure, find the maximum number $l \in [0, m-1]$ for which $[G : G^{(l+1)}] = \prod_{j=0}^{l} [G_j : K_j]$, and then a transversal $T$ of the group $G^{(m)}$ in the group $G^{(l)}$.

**Step 4.** For each $t \in T$, recursively find the set $X_t = \text{A3'}(H, tc)$, where $H = G^{(m)}$. The output $X$ equals $\bigcup_{t \in T} X_t$.

**Theorem 6.1.** Algorithm A3' finds a set $X \subseteq Gc$ such that $Gc = \bigcup_{g \in G} X^g$ in time $(nr)^{O(1)}$, where $n = |V|$ and $r = |G_0|$. Moreover, $|X| \leq |G_0|$.

**Proof.** We prove this theorem by induction on $r$. If $r = 1$, then $G = \{1\}$, and we are done (see Step 1). Suppose that $r > 1$.

In order to prove the consistency of the algorithm, we first verify that if $H$ and $T$ are found at Steps 2 and 3, then each pair $(H, tc)$ with $t \in T$ is an admissible input of the algorithm. Indeed, since $H \leq G$, relations (19) imply that $(V_i)^H = V_i$ and $(V_i)^c = V_{i+1}$ for all $i$. Furthermore, $K_i$ is a normal subgroup of $G_i$, and $(K_i)^c = K_{i+1}$ (see Steps 1 and 2), whence $H^c = H$. Next, in accordance with Steps 1 and 3, we have $H_0 \leq K_0 < G_0$, where $H_0 = \varphi_0(H)$. Therefore, by the induction hypothesis,

\begin{equation}
Htc = \bigcup_{h \in H} (X_i)^h, \quad t \in T,
\end{equation}

(20)
where $X_i$ is the set found at Step 4. To complete the proof of consistency we let $fc \in Gc$. Then for every $g \in G$ we have

$$(g^{-1}fg^{-1})_i = g_i^{-1}f_i(g_{i+1})^{-1}, \quad 0 \leq i \leq m - 2.$$  

On the other hand, from the definition of $l$ at Step 3 it follows that the natural homomorphism $G \to \prod_{j=0}^l(G_j/K_j)$ is in fact an epimorphism. This allows us to choose $g$ in such a way that the right-hand side of the above identity belongs to $K_i$ for all $i \in [0, l - 1]$. Then $g^{-1}fg^{-1} \in G^{(l)}$ (see Step 2), which shows that the element $(fc)^g$ (equal to $g^{-1}fg = (g^{-1}fg^{-1})c$) belongs to $G^{(l)}c$. Thus, we have

$$Gc = \bigcup_{g \in G} (G^{(l)}c)^g = \bigcup_{g \in G} (Htc)^g.$$  

By (20), this implies that

$$Gc = \bigcup_{g \in G} \bigcup_{t \in T} (Htc)^g = \bigcup_{g \in G} \bigcup_{t \in T} \bigcup_{h \in H} (X_t)^h = \bigcup_{g \in G} \bigcup_{t \in T} X^g,$$

completing the consistency proof.

For the rest of the proof we need the following lemma.

**Lemma 6.2.** In the notation of the algorithm, we have $[G^{(l)} : H] \leq [G_0 : H_0]$, where $H_0 = \varphi_0(H)$.

**Proof.** Since

$$[G^{(l)} : G^{(l+1)}] = [G_l : K_l] = [G_0 : K_0] \leq [G_0 : H_0],$$

it suffices to check that $H = G^{(l+1)}$. For this, we observe that the kernel of the natural epimorphism $G \to \prod_{j=0}^l(G_j/K_j)$ equals $G^{(l+1)}$ and contains $H$. Thus, we only need to show that the induced epimorphism

$$(21)\quad G/H \to \prod_{j=0}^l(G_j/K_j)$$

is in fact an isomorphism. By the definition of $H$, it suffices to verify that $(G^{(i)})_{i+1} \leq K_i$ for all $i \in [l + 1, m - 1]$. Without loss of generality, we may assume that $l < m - 1$. Since, obviously, $(G^{(i)})_{i+1}$ is a normal $c_{m+1}$-invariant subgroup of $G_i$ and $K_i = (K_0)^c_i$ for all $i$, the claim for $i = l + 1$ follows from the choice of $K_0$ at Step 1 and $l$ at Step 3. Suppose that the claim is true for some $i \in [l + 1, m - 2]$. Then

$$(G^{(i+1)})_{i+1} = (\varphi_{[0,i]}^{-1}(\prod_{j=0}^i K_j))_{i+1} \leq (\varphi_{[1,i]}^{-1}(\prod_{j=1}^i K_j))_{i+1}$$

$$= ((\varphi_{[0,i-1]}^{-1}(\prod_{j=0}^{i-1} K_j))_i)^c = ((G^{(i)})_i)^c \leq (K_i)^c = K_{i+1},$$

and we are done. $\square$

To estimate $|X|$, observe that $|X_t| \leq |H_0|$ for all $t \in T$ by the induction hypothesis. On the other hand, from Lemma 6.2 it follows that $|T| = [G^{(l)} : H] \leq [G_0 : H_0]$. Thus,

$$|X| = \sum_{t \in T} |X_t| \leq |T||H_0| \leq [G_0 : H_0]|H_0| = |G_0|.$$  

To estimate complexity, we denote by $t(G, c)$ the running time of the algorithm applied to the pair $(G, c)$. From the inequality $[G^{(i-1)} : G^{(i)}] \leq r$, $i \in [m]$, and Lemma 5.2, it follows that Steps 1–3 can be done in time $(nr)^{O(1)}$ (see Subsection 5.3). The same lemma
implies that the number of recursion calls at Step 4 is at most \( \tau = [G_0 : K_0] \leq [G_0 : H_0] \).
So, by the induction hypothesis we have
\[
t(G, c) \leq (nr)^{O(1)} + \tau(nr/\tau)^{O(1)},
\]
which completes the proof of the theorem.

\[\square\]

6.2. We describe the main algorithm of this section. Let \( c = (v_1, \ldots, v_n) \) and \( c' = (v'_1, \ldots, v'_n) \) be full cycles on \( V \). It is easily seen that
\[
\{ g \in \text{Sym}(V) : g^{-1}cg = c' \} = \langle c \rangle g_0,
\]
where \( g_0 \) is the permutation of \( V \) taking \( v_i \) to \( v'_i \) for all \( i \). Thus, if \( G \leq \text{Sym}(V) \) is an \( n^{O(1)} \)-recognizable permutation group \footnote{Here the group \( G \) is not assumed to be given by generators.}, then, by checking whether or not \( c'g_0 \in G \) for some \( i \in [n] \), we can test in time \( n^{O(1)} \) whether or not \( c \) and \( c' \) are \( G \)-conjugate. In particular, if \( Y \subset \text{Cyc}(V) \), then the family \( \mathfrak{F}_G(Y) \) of all \( G \)-conjugacy classes of \( Y \) (and then a transversal of that family) can be found in time \( (n|Y|)^{O(1)} \).

Algorithm A3.

Input: a permutation group \( G \leq \text{Sym}(V) \).
Output: a cycle base \( C \) of \( G \).

Step 1. If \( G \) is not transitive, then \( C = \emptyset \).
Step 2. If \( |V| = 1 \), then \( C = G \). Otherwise, find a minimal element \( E \) in the set of all \( G \)-invariant equivalences on \( V \) other than \( \Delta(V) \).
Step 3. Construct the groups \( G_{V/E} \) and \( G_E = \{ g \in G : g_{V/E} = \text{id}_{V/E} \} \). Recursively find the set \( \mathfrak{C} = \mathfrak{A}^3(G_{V/E}) \).
Step 4. For each \( \tau \in \mathfrak{C} \), find \( c \in G \) such that \( c_{V/E} = \tau \) and then the set \( X_c = \mathfrak{A}^3(G_E, c) \) (the decomposition \footnote{Here the group \( G \) is not assumed to be given by generators.} is given by the classes of \( E \)).
Step 5. As the output \( C \), take a transversal of the family \( \mathfrak{F}_G(\text{Cyc}(X)) \), where \( X = \bigcup_{c \in \mathfrak{C}} X_c \).

Theorem 6.3. Algorithm A3 finds a cycle base of the group \( G \). If \( G \) is solvable, then this algorithm runs in time \( n^{O(1)} \), where \( n \) is the degree of \( G \).

Proof. For the proof of consistency it suffices to verify that, if the group \( G \) is transitive, then every full cycle of \( G \) is conjugate in \( G \) to some element of \( C \). Let \( c' \in \text{Cyc}(G) \). Then \( c'_{V/E} \in \text{Cyc}(G_{V/E}) \), whence it follows by induction that \( c'_{V/E} \) is conjugate in \( G_{V/E} \) to some element \( \tau \in \mathfrak{C} \). This implies that \( c' \) is conjugate in \( G_E \) to some element of \( G_{E \tau} \) and, consequently, to some element of \( X_c \) by Theorem 6.1. Thus, \( c' \) is conjugate in \( G \) to some element of \( C \) by the choice of \( C \) at Step 5.

We estimate the running time \( t(G) \) of the algorithm applied to a solvable group \( G \). First, we observe that Steps 1 and 2 can easily be done in time \( n^{O(1)} \). The running time of Step 3 is \( t(G_{V/E}) + n^{O(1)} \). By Theorem 6.1, the running time of Step 4 is \( |\mathfrak{C}|(n^{O(1)} + (n|G_0|)^{O(1)}) \), where \( G_0 = (G_E)_{V_0} \) and \( V_0 \) is a fixed class of \( E \). Finally, Step 5 can be done in time \( (n|X|)^{O(1)} \) (see the remark before the algorithm). From the minimality of \( E \) it follows that the group \( G_{V_0} \) is primitive. Therefore, we have \( |G_{V_0}| \leq |V_0|^4 \), by the upper bound for the order of a primitive solvable group proved in \footnote{Here the group \( G \) is not assumed to be given by generators.}. Next, \( |X_c| \leq |G_0| \) for each \( \tau \in \mathfrak{C} \) by Theorem 6.1. Thus, \( |X| \leq |\mathfrak{C}| |V_0|^4 \leq n^4 \) because \( G_0 \leq G_{V_0} \) and \( |\mathfrak{C}| \leq |V/E| \) (see \footnote{Here the group \( G \) is not assumed to be given by generators.}). Summarizing, we obtain
\[
t(G) \leq n^{O(1)} + t(G_{V/E}),
\]
which completes the proof.
§7. CYCLE BASE OF A CELLULAR RING

Let $W$ be a homogeneous cellular ring on $V$. We set

$$E_0(W) = \{ \{R\} : R \in \mathcal{R}(W) \}. $$

Then $E_0(W) \subset E(W)$ (see Subsection 2.1). If $W$ is a Cayley ring over a cyclic group $G$, then $E_0(W) = E(W)$. Indeed, let $E \in \mathcal{E}(W)$. Then $E = H^{(G)}$ for some $H \in \mathcal{H}(\mathcal{A})$, where $\mathcal{A}$ is the S-ring over $G$ corresponding to $W$ (see Theorem 8.2). Therefore, $E = \langle R \rangle$ with $R = X^{(G)}$, where $X$ is the basic set of $\mathcal{A}$ containing a generator of $H$. However, $E_0(W) \neq E(W)$ in general. But then we can find two different relations $R, S \in \mathcal{R}(W)$ such that the equivalence $\langle R \cup S \rangle$ does not belong to $E_0(W)$. Thus, the identity $E_0(W) = E(W)$ can be tested in time $n^{O(1)}$, where $n = |V|$.

Main Algorithm.

**Input:** a cellular ring $W$ on $V$.

**Output:** a cycle base $C$ of $W$.

**Step 1.** Set $W_0 = W$ and $W' = W$.

**Step 2.** While $W' \neq \emptyset$, repeat the following: if $W'$ is not homogeneous or $E_0(W') \neq E(W')$, then the output $C$ is empty, else set $W = W'$ and find $W' = A_2(W)$.

**Step 3.** Find $G = A_1(W)$. If $G = \emptyset$, then the output $C$ is empty.

**Step 4.** Find $C' = A_3(G)$. As the output $C$, take a transversal of the family $\mathcal{F}_{\text{Aut}(W_0)}(C')$ (see Subsection 6.2).

**Theorem 7.1.** Given a cellular ring $W$ on $n$ points, the Main Algorithm finds a cycle base of $W$ in time $n^{O(1)}$.

**Proof.** For the proof of consistency, first we suppose that $\text{Cyc}(\text{Aut}(W)) = \emptyset$. Then we may assume that the algorithm terminates at Step 4. Since the cellular ring at Step 3 contains the input ring, we have $\text{Cyc}(G) = \emptyset$, where $G$ is the group found at Step 3. Thus, the consistency of the Main Algorithm follows from that of Algorithm A3 (Theorem 7.3). Now, let $\text{Cyc}(\text{Aut}(W)) \neq \emptyset$. Then, at each iteration of Step 2, $\text{Aut}(W')$ is a well-embedded subgroup of $\text{Aut}(W)$ by Theorem 6.1, consequently, $W'$ is a homogeneous ring with $E_0(W') = E(W')$ (see the beginning of the section). Therefore, at Step 3, $\text{Aut}(W)$ is a well-embedded subgroup of the automorphism group of the input ring (which is equal to $\text{Aut}(W_0)$). On the other hand, the ring $W$ at the same step is not singular. By Theorem 7.1 it follows that this ring $W$ is quasinormal. By Theorem 3.6 this implies that the group $G$ found at Step 3 is a well-embedded subgroup of $\text{Aut}(W)$ and, hence, of $\text{Aut}(W_0)$. This means that every cycle base of $G$ contains a cycle base of the input ring. Therefore, again, the consistency of the algorithm in question follows from that of Algorithm A3 (see Theorem 6.3).

We estimate the running time of the algorithm. First, we observe that the number of iterations at Step 2 is at most $n$ by Theorem 6.1. Therefore, this step can be done in time $n^{O(1)}$ by the same theorem and the remark at the beginning of the section. Thus, the required time bound follows from Theorems 8.2 and 6.3 and the remark at the beginning of Subsection 6.2 and the fact that, obviously, the group $\text{Aut}(W_0)$ at Step 4 is $n^{O(1)}$-recognizable. \hfill \square

§8. CELLULAR RINGS, CAYLEY RINGS, SCHUR RINGS, AND PERMUTATION GROUPS

In this section we cite the background on cellular rings, Schur rings, and related algorithms. The notions of a cellular ring and a Schur ring go back to [12, 25] and [25, 28], respectively. We follow [11].
8.1. Cellular rings. A subring $W$ of $\text{Mat}_V$ is called a cellular ring on $V$ if it has a (uniquely determined) $\mathbb{Z}$-base consisting of $\{0,1\}$-matrices $A(R)$, where $R$ runs over a family $\mathcal{R} = \mathcal{R}(W)$ of pairwise disjoint nonempty relations on $V$ such that

$$\Delta(V) \in \mathcal{R}^*, \quad \bigcup_{R \in \mathcal{R}} R = V^2 \quad \text{and} \quad R \cap R' = \emptyset \implies R^T \in \mathcal{R}.$$ 

Here $\mathcal{R}^* = \mathcal{R}^*(W)$ is the set of all unions of elements of $\mathcal{R}$. The elements of $V$ and $\mathcal{R}$ are called the points and the basis relations of $W$, respectively; the numbers $\deg(W) = |V|$ and $\text{rk}(W) = |\mathcal{R}|$ are called the degree and the rank. The ring $W$ is said to be homogeneous if $\Delta(V) \in \mathcal{R}$; in this case each basis relation can be treated as the set of arcs of a regular digraph on $V$. Every commutative cellular ring is homogeneous. The set of all equivalences on $V$ belonging to $\mathcal{R}^*$ is denoted by $\mathcal{E} = \mathcal{E}(W)$; the set of all classes of all of them is denoted by $\mathcal{B} = \mathcal{B}(W)$. Obviously, $\Delta(V)$ and $V^2$ belong to $\mathcal{E}$. A homogeneous ring $W$ is primitive if $\deg(W) > 1$ and $\mathcal{E} = \{\Delta(V), V^2\}$.

We say that cellular rings $W$ on $V$ and $W'$ on $V'$ are strongly isomorphic if $Wf = W'$ for some bijection $f : V \to V'$ (called a strong isomorphism from $W$ to $W'$). If $W = W'$, then the group of all strong isomorphisms contains the normal subgroup

$$\text{Aut}(W) = \{f \in \text{Sym}(V) : A^f = A, \ A \in W\},$$

called the automorphism group of $W$. The rings $W$ and $W'$ are said to be weakly isomorphic if there exists a $\mathbb{Z}$-module isomorphism $\varphi : W \to W'$ preserving both the matrix and the Hadamard (componentwise) multiplications. Any such isomorphism is called a weak isomorphism from $W$ to $W'$. From [9, Lemma 2.2] it follows that $\varphi$ induces a bijection from $\mathcal{R}^*(W)$ onto $\mathcal{R}^*(W')$, $R \mapsto R^{\varphi}$, such that $\varphi(A(R)) = A(R^{\varphi})$. Moreover, this bijection maps $\mathcal{R}(W)$ onto $\mathcal{R}(W')$ and $\mathcal{E}(W)$ onto $\mathcal{E}(W')$ with $(R^{\varphi})^T = (R^T)^\varphi$ and $|R| = |R^{\varphi}|$ for all $R \in \mathcal{R}^*(W)$. Each strong isomorphism from $W$ to $W'$ induces a weak isomorphism between these rings. For a weak isomorphism $\varphi : W \to W'$, we set

$$\text{Iso}(W, W', \varphi) = \{f \in \text{Iso}(W, W') : \varphi_f = \varphi\},$$

where $\text{Iso}(W, W')$ is the set of all strong isomorphisms from $W$ to $W'$ and $\varphi_f$ is the weak isomorphism induced by $f$. In particular, $\text{Iso}(W, W', \text{id}_W) = \text{Aut}(W)$.

Let $W$ be a homogeneous ring on $V$, and let $X \in \mathcal{B}, E \in \mathcal{E}$. Then the submodule $W_X$ of $\text{Mat}_X$ spanned by the matrices $A(R_X)$, $R \in \mathcal{R}$, is a cellular ring on $X$ (see [11]) and the submodule $W/E$ of $\text{Mat}_V/E$ spanned by the matrices $A(R_{V/E})$, $R \in \mathcal{R}$, is a cellular ring on $V/E$ (see [17, Subsection 2.2]). We observe that $E_X \in \mathcal{E}(W_X), X/E \in \mathcal{B}(W/E)$, and $W_X/E_X = (W/E)_{X/E}$. The latter cellular ring on $X/E$ is denoted by $W_{X/E}$. It can be shown that

$$\mathcal{R}(W_{X/E}) = \{R_{X/E} : R \in \mathcal{R}, \ R \cap X^2 \neq \emptyset\}. \tag{23}$$

It is easily seen that the ring $W_{X/E}$ is homogeneous, and it is commutative whenever so is $W$. The following statement is a special case of [3, Lemma 2.6].

**Lemma 8.1.** Let $W$ be a homogeneous cellular ring on $V$, and let $E \in \mathcal{E}(W)$. For any $X, Y \in V/E$ there exists a unique weak isomorphism $\varphi_{X,Y} : W_X \to W_Y$ taking $A(R_X)$ to $A(R_Y)$ for all $R \in \mathcal{R}(W)$. In particular, $|X| = |Y|$.

If $W_1$ and $W_2$ are cellular rings on $V_1$ and $V_2$, respectively, then the subring $W_1 \otimes W_2$ of the ring $\text{Mat}_{V_1} \otimes \text{Mat}_{V_2} = \text{Mat}_{V_1 \times V_2}$ is a cellular ring on $V_1 \times V_2$, and

$$\mathcal{R}(W_1 \otimes W_2) = \{R_1 \otimes R_2 : R_1 \in \mathcal{R}(W_1), \ R_2 \in \mathcal{R}(W_2)\}$$

where $R_1 \otimes R_2 = \{(u_1, v_1), (u_2, v_2) : (u_1, v_1) \in R_1, \ (u_2, v_2) \in R_2\}$. The ring $W_1 \otimes W_2$ is called the tensor product of $W_1$ and $W_2$. Obviously, $\text{Aut}(W_1 \otimes W_2) = \text{Aut}(W_1) \times \text{Aut}(W_2)$. 

The set of all cellular rings on $V$ is partially ordered by inclusion and is closed under intersection. The largest and the smallest elements of this set are, respectively, the full matrix ring $\text{Mat}_V$ and the ring with $\mathbb{Z}$-base $\{I_V, J_V\}$. We write $W \leq W'$ and call $W'$ an extension of $W$ if $W \subset W'$. If $\mathcal{M}_1, \ldots, \mathcal{M}_s$ are subsets of $\text{Mat}_V$, then their cellular closure, i.e., the smallest cellular ring on $V$ containing all of them, is denoted by $[\mathcal{M}_1, \ldots, \mathcal{M}_s]$. If $\mathcal{M}_i = \{A_i\}$, we omit the braces.

### 8.2. S-rings and Cayley rings

Let $G$ be a finite group. A subring $A$ of the group ring $\mathbb{Z}[G]$ is called a Schur ring (briefly, an S-ring) over $G$ if it has a (uniquely determined) $\mathbb{Z}$-base consisting of elements $\xi(X) = \sum_{x \in X} x$, where $X$ runs over a family $S = S(A)$ of pairwise disjoint nonempty subsets of $G$ such that

\[
\{1\} \in S, \quad \bigcup_{X \in S} X = G \quad \text{and} \quad X \in S \implies X^{-1} \in S. 
\]

We call the elements of $S$ basic sets of $A$ and denote by $S^*(A)$ the set of all unions of basic sets and by $\mathcal{H}(A)$ the set of all subgroups of $G$ belonging to $S^*(A)$. The number $\text{rk}(A) = \dim_{\mathbb{Z}}(A)$ is called the rank of $A$.

Let $H, K \in \mathcal{H}(A)$, let $K$ be a normal subgroup of $H$, and let $i : H \to G$ and $\pi : H \to H/K$ be natural homomorphisms. Then the ring $A_{H/K} = \pi(i^{-1}(A))$ is an S-ring over the group $H/K$, and

\[
S(A_{H/K}) = \{\pi(X) : X \in S(A), \ X \subset H\}
\]

(we keep the notation $i$ and $\pi$ also for the induced homomorphisms of the corresponding group rings).

If $A_1$ and $A_2$ are S-rings over groups $G_1$ and $G_2$, respectively, then the subring $A_1 \otimes A_2$ of the ring $\mathbb{Z}[G_1] \times \mathbb{Z}[G_2] = \mathbb{Z}[G_1 \times G_2]$ is an S-ring over the group $G_1 \times G_2$, and

\[
S(A_1 \otimes A_2) = \{X_1 \times X_2 : X_1 \in S(A_1), \ X_2 \in S(A_2)\}.
\]

The ring $A_1 \otimes A_2$ is called the tensor product of $A_1$ and $A_2$.

For $g \in G$, we denote by $P_g$ the permutation matrix corresponding to the left multiplication by $g$. Then the mapping

\[
\rho_G : \mathbb{Z}[G] \to \text{Mat}_G, \quad g \mapsto P_g,
\]

is a ring monomorphism the image of which is the enveloping ring of the group $G_{\text{left}}$. This monomorphism induces a bijection $X \mapsto X^{\rho_G}$ between the subsets of $G$ and the $G_{\text{right}}$-invariant relations on $G$, and $A(X^{\rho_G}) = \rho_G(\xi(X))$ for all $X$. If $A$ is an S-ring over $G$, then $W = A^{\rho_G}$ is a cellular ring on $G$ such that $G_{\text{right}} \leq \text{Aut}(W)$. Any such cellular ring is called a Cayley ring over $G$. It is always homogeneous, and it is commutative whenever $G$ is. The following statement can be found in [11].

**Theorem 8.2.** The mapping [24] determines a bijection $A \mapsto W$ between the S-rings over $G$ and the Cayley rings over $G$. Moreover, $S(A)^{\rho_G} = \mathcal{R}(W)$, $S^*(A)^{\rho_G} = \mathcal{R}^*(W)$, $\mathcal{H}(A)^{\rho_G} = \mathcal{E}(W)$, and for $H, K \in \mathcal{H}(A)$ with $K$ normal in $H$, we have $G/E = \{Hg : g \in G\}$ and $\rho_{H/K}(A_{H/K}) = W_{H/K}$, where $E = H^{\rho_G}$ and $E' = K^{\rho_G}$.

Let $X \subset G$; the group $\text{rad}(X) = \{g \in G : gX = Xg = X\}$ is called the radical of $X$. It is the largest subgroup of $G$ such that $X$ is a union of left as well as right cosets by this subgroup. If this subgroup is normal in $G$, then the image of $X$ under the natural epimorphism from $G$ to $G/\text{rad}(X)$ has a trivial radical. If $X \in S^*(A)$, where $A$ is an S-ring over $G$, then $\text{rad}(X) \in \mathcal{H}(A)$. If $H, K \in \mathcal{H}(A)$ and $K \leq H$, then we say that $A$ satisfies the $H/K$-condition if $K \leq \text{rad}(X)$ for all $X \in S(A)$ with $X \subset G \setminus H$.
8.3. Algorithms. A cellular ring $W$ on $n$ points will always be determined by a set of basis relations (or their adjacency matrices). In this representation, its homogeneity, commutativity, and primitivity can be tested in time $n^{O(1)}$. Also, given $X \in \mathcal{E}(W)$ and $E \in \mathcal{E}(W)$, we can construct the cellular ring $W_{X/E}$ within the same time. As to the cellular closure of a set of matrices, we note that, historically, the first method of finding it was described in [20] and, in more detail, in [27], where in fact the following statement was proved.

Theorem 8.3. For a finite set $\mathcal{M} \subseteq \text{Mat}_V$, the basis relations of the cellular closure of $\mathcal{M}$ can be found in time $mn^{O(1)}$, where $m = |\mathcal{M}|$ and $n = |V|$. Moreover, if $\varphi : \mathcal{M} \rightarrow \mathcal{M}'$ is a bijection, where $\mathcal{M}' \subseteq \text{Mat}_V'$, then within the same time we can test whether there exists a weak isomorphism from this ring onto the cellular closure of $\mathcal{M}'$ that coincides with $\varphi$ on $\mathcal{M}$, and find it if it does exist.

The permutation group algorithms used in this paper are standard; mostly, they are based on the sift procedure (for the details, see [16]). Here we only make some remarks. A permutation group $G$ on $n$ points will always be determined by a strong generating set (of at most $n^2$ generators). In this representation, the membership in $G$ can be tested and the order of $G$ can be found in time $n^{O(1)}$. Moreover, within the same time we can find any $n^{O(1)}$-recognizable subgroup of $G$ of index at most $n^c$, where $c > 0$, and, consequently, any permutation group $G_{X/E} = \{g_{X/E} : g \in G, X^g = X\}$ and the setwise stabilizer of $X$ in $G$, where $E$ is a $G$-invariant equivalence and $X$ is a block of $G$. If $K$ is a permutation group on the same set as $G$, then the normal closure of $G$ with respect to $K$ can also be found in time $n^{O(1)}$. Finally, the following statement (to be used in [34] is a special case of [1 Corollary 3.6].

Theorem 8.4. Let $G \leq \text{Sym}(V)$ be a solvable group. For a cellular ring $W \leq \text{Mat}_V$, the group $\text{Aut}(W) \cap G$ can be found in time $n^{O(1)}$, where $n = |V|$.
