UNIFORM SUBALGEBRAS OF $L^\infty$ ON THE UNIT CIRCLE GENERATED BY ALMOST PERIODIC FUNCTIONS

A. BRUDNYI AND D. KINZEBULATOV

Abstract. Analogs of almost periodic functions for the unit circle are introduced. Certain uniform algebras generated by such functions are studied, the corona theorems for them are proved, and their maximal ideal spaces are described.

§1. FORMULATION OF MAIN RESULTS

1.1. The classical almost periodic functions on the real line, as first introduced by H. Bohr in the 1920s, play an important role in various areas of analysis. In the present paper we define analogs of almost periodic functions on the unit circle. We study certain uniform algebras generated by such functions. In particular, in these terms we describe some uniform subalgebras of the algebra $H^\infty$ of bounded holomorphic functions on the open unit disk $D \subset \mathbb{C}$ that, in a sense, have the weakest possible discontinuities on the boundary $\partial D$.

To formulate the main results of the paper, we start with recalling the definition of an almost periodic function; see [B].

Definition 1.1. A continuous function $f : \mathbb{R} \to \mathbb{C}$ is said to be almost periodic if, for any $\epsilon > 0$, there exists $l(\epsilon) > 0$ such that for every $t_0 \in \mathbb{R}$ the interval $[t_0, t_0 + l(\epsilon)]$ contains at least one number $\tau$ for which $|f(t) - f(t + \tau)| < \epsilon$ for all $t \in \mathbb{R}$.

It is well known that every almost periodic function $f$ is uniformly continuous and is the uniform limit of a sequence of exponential polynomials $\{q_n\}_{n \in \mathbb{N}}$, where $q_n(t) := \sum_{k=1}^{n} c_{kn} e^{i\lambda_{kn} t}$, $c_{kn} \in \mathbb{C}$, $\lambda_{kn} \in \mathbb{R}$, $1 \leq k \leq n$, and $i := \sqrt{-1}$.

In what follows we consider $\partial D$ with the counterclockwise orientation. For $t_0 \in \mathbb{R}$, let $\gamma_{t_0} = \{e^{i(t_0 + kt)} : 0 < t < s \leq 2\pi\} \subset \partial D$, $k \in \{-1, 1\}$, be two open arcs having $e^{it_0}$ as the right or the left endpoint relative to the chosen orientation, respectively.

We define almost periodic functions on open arcs of $\partial D$.

Definition 1.2. A continuous function $f_k : \gamma_{t_0} \to \mathbb{C}$, $k \in \{-1, 1\}$, is said to be almost periodic if the function $\hat{f}_k : (-\infty, 0) \to \mathbb{C}$, $\hat{f}_k(t) := f_k(e^{i(t_0 + kse^t)})$, is the restriction of an almost periodic function on $\mathbb{R}$.

Example 1.3. In the sense of this definition, the function $e^{i\lambda \log_{t_0}}$, $\lambda \in \mathbb{R}$, where $\log_{t_0}(e^{i(t_0 + kt)}) := \ln t$, $0 < t < 2\pi$, $k \in \{-1, 1\}$, is almost periodic on $\gamma_{t_0}(2\pi) = \gamma_{t_0}(2\pi)$.

Key words and phrases. Bounded holomorphic function, almost periodic function, uniform algebra, maximal ideal space, corona theorem.
Supported in part by NSERC.
By \( \text{SAP}(\partial \mathbb{D}) \subset L^\infty(\partial \mathbb{D}) \) we denote the uniform subalgebra of functions \( f \) such that for each \( t_0 \) and any \( \epsilon > 0 \) there is a number \( s := s(t_0, \epsilon) \in (0, \pi) \) and almost periodic functions \( f_k : \gamma_{t_0}^s(s) \to \mathbb{C} \), \( k \in \{-1, 1\} \), such that
\[
\lim_{t \rightarrow 0^+} g(e^{it}) = 1, \quad \lim_{t \rightarrow 2\pi^-} g(e^{it}) = 0,
\]
and \( g(e^{it}) \) is monotone decreasing for \( 0 < t < 2\pi \). We set \( g_{t_0}(e^{it}) := g(e^{i(t_0+t)}) \).

**Theorem 1.5.** The algebra \( \text{SAP}(S) \) is the uniform closure in \( L^\infty(\partial \mathbb{D}) \) of the algebra of complex polynomials in variables \( g_{t_0} \) and \( e^{i\lambda \log R} \), \( \lambda \in \mathbb{R} \), \( e^{it_0} \in \mathbb{S} \), \( k \in \{-1, 1\} \).

Let \( \phi : \partial \mathbb{D} \to \partial \mathbb{D} \) be a \( C^1 \) diffeomorphism. We denote by \( \phi^* : L^\infty(\partial \mathbb{D}) \to L^\infty(\partial \mathbb{D}) \), \( \phi^*(f) := f \circ \phi \), the pullback by \( \phi \) and put \( \tilde{S} := \phi(S) \). As a consequence of Theorem 1.5 we obtain the following.

**Corollary 1.6.** \( \phi^* \) maps \( \text{SAP}(\tilde{S}) \) isomorphically onto \( \text{SAP}(S) \).

**1.2.** We say that a complex-valued function \( g \in L^\infty(\partial \mathbb{D}) \) has a discontinuity of the first kind at \( x_0 \) if the one-sided limits of \( g \) at \( x_0 \) exist but have distinct values. For a closed subset \( S \subset \partial \mathbb{D} \), we denote by \( R_S \subset L^\infty(\partial \mathbb{D}) \) the uniform algebra of complex functions allowing discontinuities of the first kind at points of \( S \) and continuous on \( \partial \mathbb{D} \setminus S \). The elements of \( R_S \) are often referred to as regulated functions [13]. Clearly, \( R_S \hookrightarrow \text{SAP}(S) \).

Also, we shall show (see Lemma 3.1 below) that \( R_S \) is the uniform closure of the algebra generated by all possible subalgebras \( R_F \) with finite \( F \subset S \).

Let \( \mathcal{M}(\text{SAP}(S)) \) be the maximal ideal space of \( \text{SAP}(S) \), that is, the space of all characters (\( = \) nonzero homomorphisms \( \text{SAP}(S) \to \mathbb{C} \)) on \( \text{SAP}(S) \) equipped with the weak* topology (also known as the Gelfand topology) inherited from \( (\text{SAP}(S))^* \). By definition, \( \mathcal{M}(\text{SAP}(S)) \) is a compact Hausdorff space. The main result formulated in this section describes the topological structure of \( \mathcal{M}(\text{SAP}(S)) \).

Consider the continuous embeddings of uniform algebras
\[
C(\partial \mathbb{D}) \hookrightarrow R_S \hookrightarrow \text{SAP}(S).
\]
The maps dual to these embeddings determine continuous surjective maps of the corresponding maximal ideal spaces:
\[
\mathcal{M}(\text{SAP}(S)) \overset{R_S}{\rightarrow} \mathcal{M}(R_S) \overset{c_S}{\rightarrow} \mathcal{M}(C(\partial \mathbb{D})) \cong \partial \mathbb{D}.
\]

**Theorem 1.7.**
1. For each \( z \in S \), the preimage \( c_S^{-1}(z) \) consists of two points \( z_+ \) and \( z_- \), which are identified naturally with the counterclockwise and clockwise orientations of \( \partial \mathbb{D} \) at \( z \).
2. \( c_S : \mathcal{M}(R_S) \setminus c_S^{-1}(S) \to \partial \mathbb{D} \setminus S \) is a homeomorphism.
3. \( c_S^{-1}(S) \subset \mathcal{M}(R_S) \) is a totally disconnected compact Hausdorff space.
UNIFORM SUBALGEBRAS OF \( L^\infty \) ON THE UNIT CIRCLE

(4) For each \( \xi \in c_S^{-1}(S) \), the preimage \( r_S^{-1}(\xi) \) is homeomorphic to the Bohr compactification \( bR \) of \( \mathbb{R} \).

(5) The map \( r_S : M(SAP(S)) \setminus (c_S \circ r_S)^{-1}(S) \to M(R_S) \setminus c_S^{-1}(S) \cong \partial \mathbb{D} \setminus S \) is a homeomorphism.

We recall that \( bR \) is a compact Abelian topological group homeomorphic to the maximal ideal space of the algebra of continuous almost periodic functions on \( \mathbb{R} \). Also, (2)–(5) imply straightforwardly that

(6) the covering dimension of \( M(SAP(S)) \) is \( \infty \);

(7) for a continuous map \( \phi : T \to (c_S \circ r_S)^{-1}(S) \) of a connected topological space \( T \), there is a point \( \xi \in c_S^{-1}(S) \) such that \( \phi(T) \subset r_S^{-1}(\xi) \).

1.3. Let \( A_0 \subset H^\infty \) denote the disk-algebra, i.e., the algebra of functions continuous on the closure \( \overline{D} \) and holomorphic in \( D \). Also, by \( f|_{\partial D} \) we denote the boundary values of \( f \in C(\overline{D}) \) (if they exist). In the present part we describe the uniform subalgebras of \( H^\infty \) generated by almost periodic functions. These subalgebras contain \( A_0 \) and have, in a sense, the weakest possible discontinuities on \( \partial \mathbb{D} \).

Suppose that \( S \) contains at least two points. Let \( A_S \subset H^\infty \) denote the uniform closure of the algebra generated by \( A_0 \) and by the holomorphic functions of the form \( e^{\lambda f} \), where \( \text{Re}f|_{\partial D} \) is a finite linear combination with real coefficients of characteristic functions of closed arcs whose endpoints belong to \( S \). If \( S \) consists of a single point, we define \( A_S \subset H^\infty \) to be the uniform closure of the algebra generated by \( A_0 \) and the functions \( ge^{\lambda f} \), \( \lambda \in \mathbb{R} \), where \( \text{Re}f|_{\partial D} \) is the characteristic function of a closed arc with an endpoint at \( S \), and \( g \in A_0 \) is a function such that \( ge^{\lambda f} \) has discontinuity on \( S \) only. In the following result we naturally identify \( A_S \) and \( H^\infty \) with the algebras of their boundary values.

**Theorem 1.8.**

\[ A_S = \text{SAP}(S) \cap H^\infty. \]

**Remark 1.9.** Suppose that \( S \subset \partial \mathbb{D} \) contains at least two points. Let \( e^{\lambda f} \in A_S \), \( \lambda \in \mathbb{R} \), where \( \text{Re}f \) is the characteristic function of an arc \( [x, y] \) with \( x, y \in S \). Let \( \phi_{x,y} : \mathbb{D} \to \mathbb{H}_+ \), where \( \mathbb{H}_+ \) is the upper half-plane

\[ S = \{z_1, z_2, z_3, z_4\} \]

![Figure 1](https://example.com/figure1.png)

**Figure 1.** For a given \( S = \{z_1, z_2, z_3, z_4\} \), \( c_S \) is a homeomorphism of \( M(R_S) \setminus \{z_{1+}, z_{1-}, z_{2+}, z_{2-}, z_{3+}, z_{3-}, z_{4+}, z_{4-}\} \) and \( \partial \mathbb{D} \setminus \{z_1, z_2, z_3, z_4\} \), where \( c_S(z_{i+}) = c_S(z_{i-}) = z_i \).
Given an \( n \) point set \( S \), the maximal ideal space \( M(SAP(S)) \) is the union of \( \partial D \setminus S \) and 2\( n \) Bohr compactifications of \( \mathbb{R} \) that can be viewed as infinite-dimensional “tori”; the spirals joining the arcs and the tori indicate (figuratively) that the topology of the Bohr compactifications affects the topology of the arcs.

be the bilinear map onto the upper half-plane that maps \( x \) to 0, the midpoint of the arc \([x, y]\) to 1, and \( y \) to \( \infty \). Then there is a constant \( C \) such that

\[
e^{\lambda f}(z) = e^{-\frac{i\lambda}{2\pi} \text{Log} \phi_{x,y}(z)} + \lambda C, \quad z \in D,
\]

where \( \text{Log} \) denotes the principal branch of the logarithmic function. Thus, by Theorem 1.8, the algebra \( SAP(S) \cap H^\infty \) is the uniform closure of the algebra generated by \( A_0 \) and the functions \( e^{i\lambda (\text{Log} \circ \phi_{x,y})} \), \( \lambda \in \mathbb{R}, x, y \in S \).

The following example shows that if \( S \) is an infinite set, then \( A_S \) does not coincide with the uniform algebra generated by the functions \( e^f \) with \( \text{Re} f \in R_S \) (the corresponding arguments are presented in Subsection 4.3).

**Example 1.10.** Assume that a closed subset \( S \subset \partial \mathbb{D} \) contains \(-1, 1\), and a sequence \( \{e^{it_k}\}_{k \in \mathbb{N}}, t_k \in (0, \pi/2) \), converging to 1. Let \( \{\alpha_k\}_{k \in \mathbb{N}} \) be a sequence of positive numbers satisfying \( \sum_{k=1}^{\infty} \alpha_k = 1 \). Let \( \chi_k \) denote the characteristic function of the arc \( \gamma_k := \{e^{it} : t_k \leq t \leq \pi\} \). Consider the function

\[
u(z) := \sum_{k=1}^{\infty} \alpha_k \chi_k(z), \quad z \in \partial \mathbb{D}.
\]

Clearly, \( \nu \in R_S \). Let \( h \) be a holomorphic function on \( \mathbb{D} \) such that \( \text{Re} h|_{\partial \mathbb{D}} = \nu \). Then \( e^h \in H^\infty \setminus A_S \). However, for any \( f \in A_0 \) with \( f(1) = 0 \) we have \( fe^h \in A_S \).
1.11. **Remark.** It seems to be natural that a function \( f \in H^\infty \) has the weakest possible discontinuities on \( \partial \mathbb{D} \) if \( f|_{\partial \mathbb{D}} \in R_S \). However, from the classical Lindelöf theorem \(^1\) it follows that, in fact, any such \( f \) belongs to \( A_0 \). Moreover, the same conclusion is obtained even from the fact that \( \text{Ref} f|_{\partial \mathbb{D}} \in R_S \) for \( f \in H^\infty \). In particular, if \( f \) is holomorphic on \( \mathbb{D} \) and \( \text{Ref} f|_{\partial \mathbb{D}} \) is well defined and belongs to \( R_S \setminus C(\partial \mathbb{D}) \), then \( f \not\in H^\infty \). Nevertheless, we have \( e^f \in H^\infty \), which partly explains the choice of the object of our research.

Let \( \mathcal{M}(A_S) \) be the maximal ideal space of \( A_S \). Since the evaluation functionals \( z(f) := f(z) \), \( z \in \mathbb{D} \), \( f \in A_S \), belong to \( \mathcal{M}(A_S) \), and \( A_S \) separates the points on \( \mathbb{D} \), there is a continuous embedding \( i_S : \mathbb{D} \to \mathcal{M}(A_S) \). In the sequel we identify \( \mathbb{D} \) with \( i_S(\mathbb{D}) \). Then the following corona theorem is true.

**Theorem 1.12.** \( \mathbb{D} \) is dense in \( \mathcal{M}(A_S) \).

1.13. **Remark.** Recall that the corona theorem is equivalent to the following statement (see, e.g., \([1], \) Chapter \( V \)):

For any collection of functions \( f_1, \ldots, f_n \in A_S \) satisfying the corona condition

\[
\max_{1 \leq j \leq n} |f_j(z)| \geq \delta > 0, \quad z \in \mathbb{D},
\]

there exist functions \( g_1, \ldots, g_n \in A_S \) such that

\[
f_1g_1 + \cdots + f_ng_n = 1.
\]

Finally, we formulate some results on the structure of \( \mathcal{M}(A_S) \). Since \( A_0 \hookrightarrow A_S \), there is a continuous surjection

\[ a_S : \mathcal{M}(A_S) \to \mathcal{M}(A_0) \cong \mathbb{D} \]

of maximal ideal spaces. Recall that the \( \check{\text{Š}} \)ilov boundary of \( A_S \) is the smallest compact subset \( K \subset \mathcal{M}(A_S) \) such that

\[
\sup_{z \in \mathcal{M}(A_S)} |f(z)| = \sup_{\xi \in K} |f(\xi)|
\]

for each \( f \in A_S \). Here we assume that every \( f \in A_S \) is also defined on \( \mathcal{M}(A_S) \); its extension to \( \mathcal{M}(A_S) \setminus \mathbb{D} \) is given by the Gelfand transform \( f(\xi) := \xi(f), \xi \in \mathcal{M}(A_S) \).

**Theorem 1.14.**

1. \( a_S : \mathcal{M}(A_S) \setminus a_S^{-1}(S) \to \mathbb{D} \setminus S \) is a homeomorphism.
2. The \( \check{\text{Š}} \)ilov boundary \( K_S \) of \( A_S \) is naturally homeomorphic to \( \mathcal{M}(\text{SAP}(S)) \). Under the identification of \( K_S \) and \( \mathcal{M}(\text{SAP}(S)) \), we have \( a_S|_{K_S} = \tau_S \circ c_S \).
3. For each \( z \in S \), the preimage \( a_S^{-1}(z) \) is homeomorphic to the maximal ideal space of the algebra \( \text{AP}_0(\Sigma) \) of uniformly continuous almost periodic functions defined on the strip \( \Sigma := \{ z \in \mathbb{C} : \text{Im} z \in [0, \pi] \} \) and holomorphic at the interior points of \( \Sigma \).

In the next section we describe the topological structure of the maximal ideal space \( \mathcal{M}(\text{AP}_0(\Sigma)) \) of \( \text{AP}_0(\Sigma) \). We show that this space is equipped with a natural “complex structure”. Similarly, each fiber \( a_S^{-1}(z), z \in S \), has a natural complex structure so that the homeomorphisms in Theorem \( 1.14(3) \) are analytic with respect to these structures.

In a forthcoming paper, we shall present similar results for algebras of bounded holomorphic functions on an open polydisk that are generated by almost periodic functions.

\(^1\)In this case \( f|_{\partial \mathbb{D}} \in \text{BMO}(\partial \mathbb{D}) \) with \( \|f\|_{\text{BMO}(\partial \mathbb{D})} \leq c\|\text{Ref} f|_{\partial \mathbb{D}}\|_{L^\infty(\partial \mathbb{D})} \) for some absolute constant \( c \).
§2. The maximal ideal space of the algebra $AP_{\mathcal{O}}(\Sigma)$

2.1. The construction presented below is rather general and makes sense for Galois coverings of complex manifolds with boundaries (cf. [H]). However, we restrict ourselves to the case of coverings of annuli related to the subject of our paper.

Consider the annulus $R := \{ z \in \mathbb{C} : e^{-2\pi z} \leq |z| \leq 1 \}$. Its universal covering can be identified with $\Sigma$ so that $e : \Sigma \to R$, $e(z) := e^{2\pi iz}$, $z \in \Sigma$, is the covering map. We can also regard $\Sigma$ as a principal bundle on $R$ with fiber $\mathbb{Z}$ (see, e.g., [H] for the corresponding topological definitions). To specify, consider a cover of $R$ by compact simply connected sets $U_1$ and $U_2$. Then $e^{-1}(U_k)$ can be identified with $U_k \times \mathbb{Z}$, $k = 1, 2$. Also, there is a continuous map $c_{12} : U_1 \cap U_2 \to \mathbb{Z}$ such that $R$ is isomorphic (in the category of complex manifolds with boundaries) to the quotient space of $(U_1 \times \mathbb{Z}) \sqcup (U_2 \times \mathbb{Z})$ under the following equivalence relation:

$$U_1 \times \mathbb{Z} \ni (z, n) \sim (z, n + c_{12}(z)) \in U_2 \times \mathbb{Z} \quad \text{for all} \quad z \in U_1 \cap U_2 \quad \text{and} \quad n \in \mathbb{Z}.$$ 

Let $b\mathbb{Z}$ be the Bohr compactification of $\mathbb{Z}$. Then the action of $\mathbb{Z}$ on itself by translations extends naturally to the action on $b\mathbb{Z}$: $\xi \mapsto \xi + n$, $\xi \in b\mathbb{Z}$, $n \in \mathbb{Z}$. Let $E(R, b\mathbb{Z})$ denote the principal bundle on $R$ with fiber $b\mathbb{Z}$ defined as the quotient of $(U_1 \times b\mathbb{Z}) \sqcup (U_2 \times b\mathbb{Z})$ under the following equivalence relation:

$$U_1 \times b\mathbb{Z} \ni (z, \xi) \sim (z, \xi + c_{12}(z)) \in U_2 \times b\mathbb{Z} \quad \text{for all} \quad z \in U_1 \cap U_2 \quad \text{and} \quad \xi \in b\mathbb{Z}.$$ 

Clearly, $E(R, b\mathbb{Z})$ is a compact Hausdorff space in the quotient topology induced by that of $(U_1 \times b\mathbb{Z}) \sqcup (U_2 \times b\mathbb{Z})$. Also, the projection $p : E(R, b\mathbb{Z}) \to R$ is determined by the natural projections $U_k \times b\mathbb{Z} \to U_k$, $k = 1, 2$, onto the first coordinate.

Next, the natural local injections $U_k \times \mathbb{Z} \to U_k \times b\mathbb{Z}$, $k = 1, 2$, determine an injection $i_0 : \Sigma \to E(R, b\mathbb{Z})$ such that $p \circ i_0 = e$. Moreover, $i_0(\Sigma)$ is dense in $E(R, b\mathbb{Z})$, because $\mathbb{Z}$ is dense in $b\mathbb{Z}$ (in the topology of $b\mathbb{Z}$). Similarly, we can define an injection $i_\xi : \Sigma \to E(R, b\mathbb{Z})$, $\xi \in b\mathbb{Z}$, by the formula $i_\xi((z, n)) := (z, \xi + n)$, $z \in U_k$, $n \in \mathbb{Z}$, $k = 1, 2$. Since, by definition, $\xi + \mathbb{Z}$ is dense in $b\mathbb{Z}$, the image $i_\xi(\Sigma)$ is dense in $E(R, b\mathbb{Z})$ for any $\xi$. Moreover, $E(R, b\mathbb{Z}) = \bigsqcup \iota_\xi(\Sigma)$, where the union is taken over all $\xi$ whose images in the quotient group $b\mathbb{Z}/\mathbb{Z}$ are mutually distinct. Observe also that every $i_\xi$ is a continuous map and locally an embedding.

Definition 2.1. A continuous function $f$ on $E(R, b\mathbb{Z})$ is said to be holomorphic if every function $f \circ i_\xi$ is holomorphic at the interior points of $\Sigma$.

We denote by $O(E(R, b\mathbb{Z})) \subset C(E(R, b\mathbb{Z}))$ the Banach algebra of holomorphic functions on $E(R, b\mathbb{Z})$.

Remark 2.2. By using a normal family argument and the fact that $i_\xi(\Sigma)$ is dense in $E(R, b\mathbb{Z})$, it can easily be shown that $f \in C(E(R, b\mathbb{Z}))$ is holomorphic if and only if there is $\xi \in b\mathbb{Z}$ such that $f \circ i_\xi$ is holomorphic at the interior points of $\Sigma$.

2.2. We recall that $f \in AP_{\mathcal{O}}(\Sigma)$ if $f$ is uniformly continuous with respect to the Euclidean metric on $\Sigma$, holomorphic at the interior points of $\Sigma$, and its restriction to each straight line parallel to the $x$-axis is almost periodic. In the following lemma we identify $\Sigma$ with $i_0(\Sigma) \subset E(R, b\mathbb{Z})$.

Lemma 2.3. Every $f \in AP_{\mathcal{O}}(\Sigma)$ admits a continuous extension up to a holomorphic function $\hat{f}$ on $E(R, b\mathbb{Z})$. Moreover, the correspondence $AP_{\mathcal{O}}(\Sigma) \to O(E(R, b\mathbb{Z}))$, $f \mapsto \hat{f}$, determines an isomorphism of Banach algebras.

Proof. By using the Pontryagin duality [P], it is easy to show that the closure of $\mathbb{Z}$ in $b\mathbb{R}$, the Bohr compactification of $\mathbb{R}$, is isomorphic to $b\mathbb{Z}$. In particular, the restrictions to $\mathbb{Z}$ of almost periodic functions on $\mathbb{R}$ are almost periodic functions on $\mathbb{Z}$, and the algebra
generated by the extensions of such functions to $b\mathbb{Z}$ separates points on $b\mathbb{Z}$. In a natural way, we identify every $p^{-1}(U_k)$ with $U_k \times b\mathbb{Z}$ and every $e^{-1}(U_k)$ with $U_k \times \mathbb{Z} \subset U_k \times b\mathbb{Z}$, $k = 1, 2$, and regard $f|_{e^{-1}(U_k)}$, $f \in \mathcal{AP}_\mathcal{O}(\Sigma)$, as a bounded function $f_k \in C(U_k \times \mathbb{Z})$. Then:

(a) $f_k$ is holomorphic at the interior points of $U_k \times \mathbb{Z}$;
(b) $f_k$ is uniformly continuous on $U_k \times \mathbb{Z}$ with respect to the metric $r(v_1, v_2) := |z_1 - z_2| + |n_1 - n_2|$ on $U_k \times \mathbb{Z}$, where $v_1 = (z_1, n_1)$, $v_2 = (z_2, n_2) \in U_k \times \mathbb{Z}$, and $|\cdot|$ is the Euclidean norm on $\mathbb{C}$;
(c) $f_k|_{\{z\} \times \mathbb{Z}}$ is almost periodic on $\mathbb{Z}$ for every $z \in U_k$.

To prove the lemma, it suffices to show that

1. there is a continuous function $\hat{f}_k$ on $U_k \times b\mathbb{Z}$ such that $\hat{f}_k|_{U_k \times \mathbb{Z}} = f_k$, for every $\xi \in b\mathbb{Z}$, the function $\hat{f}_k|_{U_k \times \{\xi\}}$ is holomorphic at the interior points of $U_k$, and
$$\sup_{U_k \times b\mathbb{Z}} |\hat{f}_k| = \sup_{U_k \times \mathbb{Z}} |f_k|;
$$
2. if $f \in \mathcal{O}(E(R, b\mathbb{Z}))$, then $f|_{\Sigma} \in \mathcal{AP}_\mathcal{O}(\Sigma)$.

(1) Since for every $z \in U_k$ the function $f_k(z, n) := f_k(z, n)$ is almost periodic on $\mathbb{Z}$, there is a continuous function $\tilde{f}_k$ on $b\mathbb{Z}$ that extends $f_k$. We set $f_k(z, \xi) := f_k(z, \xi)$, $\xi \in b\mathbb{Z}$, and prove that $\tilde{f}_k$ is continuous. Indeed, take a point $w = (z, \xi) \in U_k \times b\mathbb{Z}$ and a number $\epsilon > 0$. By the uniform continuity of $f_k$, there is $\delta > 0$ such that for any pair of points $v_1 = (z_1, n_1)$ and $v_2 = (z_2, n_2)$ in $U_k \times \mathbb{Z}$ with $|z_1 - z_2| < \delta$, we have $|f(z_1, n) - f(z_2, n)| < \epsilon$. We define a neighborhood $U_k$ of $z \in U_k$ by $U_k := \{z' \in U_k : |z - z'| < \delta\}$. By the definition of $\tilde{f}_k$, there is a neighborhood $U_{\xi} \subset b\mathbb{Z}$ of $\xi$ such that $|\tilde{f}_k(\eta) - \tilde{f}_k(\xi)| < \epsilon/3$ for any $\eta \in U_k$. Consider $U_w := U_k \times U_{\xi}$. Then $U_w$ is an open neighborhood of $w \in U_k \times b\mathbb{Z}$. Note that $f_k - \tilde{f}_k$ is an almost periodic function on $\mathbb{Z}$ and for any $z' \in U_{\xi}$ its supremum norm is less than $\epsilon/3$. This implies that $|\tilde{f}_k(\eta) - \tilde{f}_k(\eta')| < \epsilon/2$ for each $\eta \in b\mathbb{Z}$. In particular, for any $(x, \eta) \in U_w$, we have
$$|\tilde{f}_k(x, \eta) - \tilde{f}_k(z, \xi)| \leq |\tilde{f}_k(\eta) - \tilde{f}_k(z, \xi)| + |\tilde{f}_k(\eta) - \tilde{f}_k(\xi)| < \epsilon.$$

This shows that $\tilde{f}_k$ is continuous at every $w \in U_k \times b\mathbb{Z}$.

Now, we show that $\hat{f}_k|_{U_k \times \{\xi\}}$ is holomorphic at the interior points of $U_k$ for every $\xi \in b\mathbb{Z}$.

Since $\tilde{f}_k$ is uniformly continuous on the compact set $U_k \times b\mathbb{Z}$, for any $\epsilon > 0$ there is $n_\epsilon \in \mathbb{Z}$ such that $\sup_{z \in U_k} |\tilde{f}_k(z, \xi) - f_k(z, n_\epsilon)| < \epsilon$. In particular, $\tilde{f}_k(\cdot, \xi)$ is the limit in $C(U_k)$ of the sequence $\{f_k(\cdot, n_1, i)|_{U_k}\}_{i \geq 1}$ of bounded continuous functions holomorphic on the interior of $U_k$. Thus, $\hat{f}_k|_{U_k \times \{\xi\}}$ is also holomorphic on the interior of $U_k$.

The identity $\sup_{U_k \times b\mathbb{Z}} |\hat{f}_k| = \sup_{U_k \times \mathbb{Z}} |f_k|$ follows directly from the definition of $\hat{f}_k$. This completes the proof of (1).

(2) Suppose that $f \in \mathcal{O}(E(R, b\mathbb{Z}))$. We must show that $f|_{\Sigma} \in \mathcal{AP}_\mathcal{O}(\Sigma)$. For this, it suffices to show that the function $f|_L$ is almost periodic for every line $L := \{z \in \mathbb{C} : \text{Im} z = t \in [0, \pi]\}$. (The uniform continuity of $f|_{\Sigma}$ with respect to the Euclidean metric on $\mathbb{C}$ follows easily from the uniform continuity of $f$ on $E(R, b\mathbb{Z})$.) By definition, the image $S := e(L) \subset R$ is a circle, and $e|_L : L \rightarrow S$ is the universal covering. Consider the compact set $p^{-1}(S) \subset E(R, b\mathbb{Z})$. Since the function $f|_{p^{-1}(S)}$ is continuous and $b\mathbb{Z} \subset b\mathbb{R}$, for any $\epsilon > 0$ a finite open cover $(V_n)_{1 \leq n \leq m}$ of $S$ by sets homeomorphic to open intervals in $\mathbb{R}$ can be found, together with continuous almost periodic functions $f_n$ on $L$, $1 \leq n \leq m$, such that

$$\sup_{z \in e^{-1}(V_n)} |f_n(z) - f(z)| < \epsilon.$$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Let \( \{ \rho_n \}_{1 \leq n \leq m} \) be a continuous partition of unity subordinate to \( \{ V_n \}_{1 \leq n \leq m} \). We pull it back to \( L \) by \( \epsilon \) and denote by \( \hat{\rho}_n \) \((:= e^i \rho_n)\), \( 1 \leq n \leq m \), the resulting functions. Since each \( \hat{\rho}_n \) is periodic on \( L \), it is almost periodic. We define a function \( f_\epsilon \) on \( L \) by the formula
\[
f_\epsilon(z) := \sum_{n=1}^{m} \hat{\rho}_n(z)f_n(z).
\]
Then, clearly, \( f_\epsilon \) is a continuous almost periodic function on \( L \), and
\[
\sup_{z \in L} |f_\epsilon(z) - f(z)| < \epsilon
\]
by (2.1). This shows that \( f \) admits a uniform approximation on \( L \) by continuous almost periodic functions, whence \( f |_L \) is almost periodic.

The lemma is proved. \( \square \)

2.3. In this part we prove the corona theorem for the algebra \( AP_\Omega(\Sigma) \). Recall that \( \mathcal{M}(AP_\Omega(\Sigma)) \) stands for its maximal ideal space. It is well known that every \( f \in AP_\Omega(\Sigma) \) can be approximated uniformly on \( \Sigma \) by polynomials in \( e^{i\lambda z} \), \( \lambda \in \mathbb{R} \) (see, e.g., [JT]). Then, using the inverse limit construction for maximal ideal spaces of uniform algebras (see [R]), we see that a base of the topology of \( \mathcal{M}(AP_\Omega(\Sigma)) \) is generated by the functions \( e^{i\lambda z} \). Namely, the base of the topology on \( \mathcal{M}(AP_\Omega(\Sigma)) \) consists of open sets of the form
\[
U(\lambda_1, \ldots, \lambda_l, \xi, \epsilon) := \{ \eta \in \mathcal{M}(AP_\Omega(\Sigma)) : \max_{1 \leq k \leq l} |e_{\lambda_k}(\eta) - e_{\lambda_k}(\xi)| < \epsilon \},
\]
where \( e_\lambda \) is the extension of \( e^{i\lambda z} \) to \( \mathcal{M}(AP_\Omega(\Sigma)) \) via the Gelfand transformation.

**Theorem 2.4.** \( \Sigma \) is dense in \( \mathcal{M}(AP_\Omega(\Sigma)) \) in the Gelfand topology.

**Proof.** Assume that the corona theorem is not true for \( AP_\Omega(\Sigma) \); that is, \( \Sigma \) is not dense in \( \mathcal{M}(AP_\Omega(\Sigma)) \). Then there exists \( \xi \in \mathcal{M}(AP_\Omega(\Sigma)) \) and its neighborhood \( U(\lambda_1, \ldots, \lambda_l, \xi, \epsilon) \) such that
\[
U(\lambda_1, \ldots, \lambda_l, \xi, \epsilon) \cap \text{cl}(\Sigma) = \emptyset;
\]
here \( \text{cl}(\Sigma) \) is the closure of \( \Sigma \) in \( \mathcal{M}(AP_\Omega(\Sigma)) \). Denoting \( c_k := e_{\lambda_k}(\xi) \), \( 1 \leq k \leq l \), we have
\[
(2.2) \quad \max_{1 \leq k \leq l} |e^{i\lambda_k z} - c_k| \geq \epsilon > 0 \quad \text{for all } z \in \Sigma.
\]
Clearly, every function \( e^{i\lambda_k z} - c_k \), \( 1 \leq k \leq l \), has at least one zero in \( \Sigma \). (Indeed, otherwise, if, say, \( e^{i\lambda_k z} - c_k \) has no zeros on \( \Sigma \), then the function \( g_k(z) := 1/(e^{i\lambda_k z} - c_k) \), \( z \in \Sigma \), obviously belongs to \( AP_\Omega(\Sigma) \) and \( g_k(z)(e^{i\lambda_k z} - c_k) = 1 \) for all \( z \in \Sigma \), which contradicts our assumption.) In particular, since the solutions of the equation
\[
e^{i\lambda_k z} = c_k, \quad \lambda_k \neq 0,
\]
are given by
\[
z = -\frac{i \ln |c_k|}{\lambda_k} + \frac{\text{Arg} c_k + 2\pi s}{\lambda_k}, \quad s \in \mathbb{Z},
\]
they all belong to \( \Sigma \). Next, without loss of generality, we may assume that all \( \lambda_k \) are positive. Indeed, if some \( \lambda_k \) is strictly negative, we can replace the function \( e^{i\lambda_k z} - c_k \) by \( e^{-i\lambda_k z} - \frac{1}{c_k} \) (observe that \( c_k \neq 0 \) by the above argument); then the new family of functions also satisfies (2.2) (possibly with a different \( \epsilon \)) and the extensions of these functions to \( \mathcal{M}(AP_\Omega(\Sigma)) \) vanish at \( \xi \). Since all these functions have zeros in \( \Sigma \) and satisfy (2.2) there, we have
\[
\max_{1 \leq k \leq l} |e^{i\lambda_k z} - c_k| \geq \bar{\epsilon} > 0 \quad \text{for all } z \in \mathbb{H}_+,
\]
where $\mathbb{H}_+ \subset \mathbb{C}$ is the open upper half-plane, and all $e^{i\lambda_k z} - c_k$, $\lambda_k \in \mathbb{R}_+$, are almost periodic on $\overline{\mathbb{H}}_+$. The above inequality and the Böttcher corona theorem (see [133]) imply that there exist holomorphic almost periodic functions $g_1, \ldots, g_l$ on $\overline{\mathbb{H}}_+$ such that
\[
\sum_{k=1}^l g_k(z)(e^{i\lambda_k z} - c_k) = 1 \quad \text{for all} \quad z \in \overline{\mathbb{H}}_+.
\]
Thus, taking the restrictions of these functions to $\Sigma$, we obtain a contradiction to our assumption.

This completes the proof of the corona theorem for $AP_O(\Sigma)$. \hfill $\square$

**Corollary 2.5.** $E(R, b\mathbb{Z})$ is homeomorphic to $\mathcal{M}(AP_O(\Sigma))$.

**Proof.** By Lemma 2.3 there exists a continuous embedding $i$ of $E(R, b\mathbb{Z})$ in $\mathcal{M}(AP_O(\Sigma))$. Since $\Sigma$ is dense in $E(R, b\mathbb{Z})$ and $i(\Sigma)$ is dense in $\mathcal{M}(AP_O(\Sigma))$ by the corona theorem, $i$ is a homeomorphism. \hfill $\square$

**Remark 2.6.** (1) In accordance with our construction, the closure of $\mathbb{R}$ in $E(R, b\mathbb{Z})$ coincides with $b\mathbb{R}$. In fact, this closure is $E(\partial \mathbb{D}, b\mathbb{Z})$, the principal bundle on $\partial \mathbb{D}$ with fiber $b\mathbb{Z}$ obtained as the restriction of $E(R, b\mathbb{Z})$ to $\partial \mathbb{D}$. Since $R$ is homotopically equivalent to $\partial \mathbb{D}$, the covering homotopy theorem shows that $E(R, b\mathbb{Z})$ is homotopically equivalent to $b\mathbb{R} = E(\partial \mathbb{D}, b\mathbb{Z})$.

(2) Observe also that the covering dimension of $b\mathbb{R}$ is $\infty$, because $b\mathbb{R}$ is the inverse limit of real tori whose dimensions go to $\infty$. Therefore, the covering dimension of $\mathcal{M}(AP_O(\Sigma)) = E(R, b\mathbb{Z})$ is also $\infty$.

(3) Finally, it is easy to show that the Šilov boundary of $AP_O(\Sigma)$ is $E(R, b\mathbb{Z})|_{\partial R}$, the restriction of $E(R, b\mathbb{Z})$ to the boundary $\partial R$ of $R$, and is homeomorphic to $b\mathbb{R} \cup \partial b\mathbb{R}$.

§3. Proofs of Theorems 1.5, 1.7 and Corollary 1.6

**3.1. Proof of Theorem 1.5.** Let $f \in SAP(S)$. Since $\partial \mathbb{D}$ is a compact set, for any $\epsilon > 0$ there are finitely many points $z_l := e^{it_l} \in \partial \mathbb{D}$, numbers $s_l \in (0, \pi)$, and almost periodic functions $f_l^k : \gamma_{t_l}^{-1}(s_l) \to \mathbb{C}$, $k \in \{-1, 1\}$, $1 \leq l \leq n$, such that
\[
\bigcup_{l=1}^n (\gamma_{t_l}^{-1}(s_l) \cup \gamma_{t_l}^+(s_l)) = \partial \mathbb{D} \setminus \{z_1, \ldots, z_n\} \quad \text{and}
\]
\[
\text{ess sup}_{z \in \gamma_{t_l}^-(s_l)} |f(z) - f_l^1(z)| < \frac{\epsilon}{2}, \quad \text{ess sup}_{z \in \gamma_{t_l}^+(s_l)} |f(z) - f_l^{-1}(z)| < \frac{\epsilon}{2}
\]
for all $1 \leq l \leq n$. We set $U_l := \gamma_{t_l}^{-1}(s_l) \cup \gamma_{t_l}^{-1}(s_l) \cup \{z_l\}$. Then $U = (U_l)_{l=1}^n$ is a finite open cover of $\partial \mathbb{D}$. Let $\{\rho_l\}_{l=1}^n$ be a continuous partition of unity subordinate to $U$ and such that $\text{supp} \rho_l \subset U_l$ and $\rho_l(z_l) = 1$, $1 \leq l \leq n$. Consider the functions $f_l$ on $\partial \mathbb{D} \setminus \{z_l\}$ defined by the formulas
\[
f_l(z) := \begin{cases} 
\rho_l(z)f_{l-1}^1(z) & \text{if } z \in \gamma_{t_l}^{-1}(s_l), \\
\rho_l(z)f_l^1(z) & \text{if } z \in \gamma_{t_l}^+(s_l).
\end{cases}
\]
Since $f_l$ is continuous outside $z_l$ and coincides with $f_{l-1}^1$ and $f_l^1$ in a neighborhood of $z_l$, $f_l$ belongs to $SAP(S)$. Moreover,
\[
||f - \sum_{l=1}^n f_l||_{L^\infty(\partial \mathbb{D})} < \frac{\epsilon}{2}.
\]
Thus, to prove the theorem it suffices to approximate every $f_l$ by polynomials in $g_l$ and $e^{i\lambda \log_{t_l}}$, $k \in \{-1, 1\}$, $\lambda \in \mathbb{R}$.
First, suppose that \( z_l \notin S \). Since \( f \) is continuous outside the compact set \( S \), we can choose the above cover \( U \) and the family of functions \( \{f_k^m\}_{1 \leq m \leq n}, k \in \{-1, 1\} \), so that in \( U_l \) the two functions \( f^m_k, k \in \{-1, 1\} \), have the same limit at \( z_l \). This implies the continuity of \( f_l \) on \( \partial D \). Next, consider the uniform algebra \( C(g_l) \) over \( \mathbb{C} \) generated by the function \( g_l \). Since by our definition \( g_l \) separates points on \( \partial D \setminus \{z_l\} \), the maximal ideal space of \( C(g_l) \) is homeomorphic to the closed interval \( (\partial D \setminus \{z_l\}) \cup \{z_k\}, k \in \{-1, 1\} \), with endpoints \( z_l \) and \( z_{l-1} \) identified with the counterclockwise and clockwise orientations at \( z_l \). Clearly, every continuous function on \( \partial D \) extends to the maximal ideal space of \( C(g_l) \) as a continuous function having the same values at \( z_l \) and \( z_{l-1} \). Thus, by the Stone–Weierstrass theorem, \( f_l \) can be uniformly approximated on \( \partial D \setminus \{z_l\} \) by complex polynomials in \( g_l \).

Now, suppose that \( z_l \in S \). Choose some \( s \in (0, s_l) \). Let \( \text{SAP}_{\{z_l\}}(s) \) denote the uniform algebra of complex continuous functions on \( \partial D \setminus \{z_l\} \) almost periodic on the open arcs \( \gamma_{s_l}^k(s), k \in \{-1, 1\} \). (Since \( s \in (0, \pi) \), the closures of these arcs are disjoint.) We denote by \( M_{\{z_l\}}(s) \) the maximal ideal space of \( \text{SAP}_{\{z_l\}}(s) \). Then \( \partial D \setminus \{z_l\} \) is dense in \( M_{\{z_l\}}(s) \) (in the Gelfand topology). Note that the space \( M_{\{z_l\}}(s) \) is constructed as follows.

Consider the Bohr compactification \( bR \) of \( \mathbb{R} \). We identify the negative ray \( \mathbb{R}_- \) in \( \mathbb{R} \subset bR \) with \( \gamma_{s_l}^1(s) \subset \partial D \) via the map \( t \mapsto e^{i(t + s_l)}, t \in \mathbb{R} \). Similarly, consider another copy of \( bR \) and identify \( \mathbb{R}_-(\subset \mathbb{R}) \) in this copy with \( \gamma_{s_l-1}(s) \subset \partial D \) via the map \( t \mapsto e^{i(t - s_l)}, t \in \mathbb{R}_- \). The identified sets are equipped with the topology induced from \( bR \), and on \( \partial D \setminus (\gamma_{s_l-1}(s) \cup \gamma_{s_l}^1(s)) \) the topology is induced from \( \partial D \). Then, under these identifications, the quotient space of \( bR \cup bR \cup \partial D \) coincides with \( M_{\{z_l\}}(s) \).

Next, we recall that, by definition, the algebra \( \text{SAP}_{\{z_l\}}(s) \) is the uniform closure in \( C(\partial D \setminus \{z_l\}) \) of the algebra generated by the algebras \( \text{SAP}_{\{z_l\}}(s), s \in (0, s_l) \). Let \( M(\text{SAP}_{\{z_l\}}(s)) \) denote the maximal ideal space of \( \text{SAP}_{\{z_l\}}(s) \). Since for any \( s'' < s \) we have the inclusions \( i_{s'' s} : \text{SAP}_{\{z_l\}}(s') \hookrightarrow \text{SAP}_{\{z_l\}}(s'') \), the space \( M(\text{SAP}_{\{z_l\}}(s)) \) is the inverse limit of the spaces \( M_{\{z_l\}}(s) \) (here the maps \( p_{s'' s} : M_{\{z_l\}}(s'') \twoheadrightarrow M_{\{z_l\}}(s') \) in the definition of this limit are defined as the maps dual to \( i_{s'' s'} \)). Also, \( \partial D \setminus \{z_l\} \) is dense in \( M(\text{SAP}_{\{z_l\}}(s)) \) in the Gelfand topology. Since, by definition, the functions \( f_l, e^{i \lambda \log_{s_l} s} \) and \( g_l \) admit continuous extensions (denoted by the same symbols) to \( M(\text{SAP}_{\{z_l\}}(s)) \), it suffices to show that the extended functions \( e^{i \lambda \log_{s_l} s}, g_l \) separate points on \( M(\text{SAP}_{\{z_l\}}(s)) \). Then we can apply the Stone–Weierstrass theorem to get a complex polynomial \( p_l \) in the variables \( e^{i \lambda \log_{s_l} s} \) and \( g_l \) that approximates \( f_l \) on \( M(\text{SAP}_{\{z_l\}}(s)) \) uniformly with an error less than \( \epsilon/2n \). Therefore, \( \sum_{l=1}^n p_l \) will approximate \( f \) in \( L^\infty(\partial D) \) with an error less than \( \epsilon \).

So, we show that the functions \( e^{i \lambda \log_{s_l} s}, g_l \) separate points on \( M(\text{SAP}_{\{z_l\}}(s)) \). Let \( p_s : M(\text{SAP}_{\{z_l\}}(s)) \rightarrow M_{\{z_l\}}(s) \) denote the continuous surjection determined by the inverse limit construction. First, we consider distinct points \( x, y \in M(\text{SAP}_{\{z_l\}}(s)) \) for which there is \( s \in (0, s_l) \) such that \( p_s(x) \) and \( p_s(y) \) are distinct and belong to one of the Bohr compactifications of \( \mathbb{R} \) in \( M_{\{z_l\}}(s) \), say, to the compactification obtained by gluing \( \mathbb{R}_- \) with \( \gamma_{s_l}^1(s) \). Since in this case the functions \( e^{i \lambda \log_{s_l} s} \) extended to \( bR \) are identified with the extensions to \( bR \) of the functions \( c_{s1} e^{i \lambda s} \) on \( \mathbb{R} \), \( c_{s1} := e^{i \lambda \log_{s_l} s} \), the classical Bohr theorem says that for some \( \lambda_0 \in \mathbb{R} \), the extension of \( e^{i \lambda_0 \log_{s_l} s} \) to \( bR \) separates \( p_s(x) \) and \( p_s(y) \). Thus, the extension of \( e^{i \lambda_0 \log_{s_l} s} \) to \( M(\text{SAP}_{\{z_l\}}(s)) \) separates \( x \) and \( y \).

Suppose now that \( x \) and \( y \) are such that \( p_s(x) \) and \( p_s(y) \) belong to different Bohr compactifications of \( \mathbb{R} \) for all \( s \). This implies that \( x \) and \( y \) are limit points of the sets \( \gamma_{s_l}^1(s) \) and \( \gamma_{s_l}^1(s) \) for some \( s \in (0, s_l) \), with \( k(x) \neq k(y) \) and \( k(x), k(y) \in \{-1, 1\} \). Then the function \( g_l \) is equal to 1 at one of the points \( x \), \( y \) and to 0 at the other point.
Finally, assume that \( x \in \mathcal{M}(\text{SAP}(\{z_l\})) \setminus \partial \mathbb{D} \) and \( y \in \partial \mathbb{D} \setminus \{z_l\} \). Then \( g_{t_i}(x) \) is equal either to 0 or to 1, and \( g_{t_i}(y) \) differs from these numbers because \( g_{t_i} \) is monotone decreasing on \( \partial \mathbb{D} \setminus \{z_l\} \).

Thus, we have proved that the family of functions \( e^{i \lambda \log_{z_l}}, g_{t_i} \) separates points on \( \mathcal{M}(\text{SAP}(\{z_l\})) \). This completes the proof of the theorem. \( \square \)

3.2. Proof of Corollary 3.3. By Theorem 3.1 it suffices to check that for the functions \( g_{t_0} \) and \( e^{i \lambda \log_{z_l}}, \lambda \in \mathbb{R}, z_0 := e^{it_0} \in \overline{S} := \phi(S), k \in \{-1, 1\}, \) the corresponding functions \( \phi^*(g_{t_0}) \) and \( f := \phi^*(e^{i \lambda \log_{z_l}}) \) belong to SAP(S). Since \( g_{t_0} \in R_{\{z_0\}} \), the statement is trivial for \( \phi^*(g_{t_0}) \). Without loss of generality, we may assume that \( \phi \) preserves the orientation on \( \partial \mathbb{D} \). Let \( e^{it_0} := \phi^{-1}(z_0) \). Then we have

\[
\phi(e^{i(t_0+t)}) = e^{i(t_0+\phi(t))}, \quad t \in [0, 2\pi],
\]

where \( \phi : [0, 2\pi) \rightarrow [0, 2\pi) \) is a \( C^1 \) diffeomorphism and \( \phi(0) = 0 \). We set \( e := \phi'(0) \). By the definition on the open arcs \( \gamma_{t_0}^1(s), \) for \( t \in (-\infty, 0) \) we obtain

\[
\tilde{f}(t) := f(e^{i(t_0+kse)}) = e^{i \lambda \ln(\phi(se^t))} = e^{i \lambda \ln(cse^t+a(e^t))} = e^{i(\lambda \ln(c)+a(1))} e^{i \lambda t}
\]

as \( s \to 0 \).

Since \( f \) is continuous outside \( e^{it_0} \), this implies that \( f \in \text{SAP}(S) \). \( \square \)

3.3. Proof of Theorem 1.7. We begin with the following statement.

**Lemma 3.1.** The algebra \( RS \) is the uniform closure of the algebra generated by the algebras \( R_{\{z_l\}} \) for all possible \( z_l \in S \).

(For \( S = \partial \mathbb{D} \), a similar statement was proved for the first time by Dieudonné [D].)

**Proof.** Consider a regulated function \( f \in R_S \). Since \( \partial \mathbb{D} \) is a compact set, the definition of \( R_S \) implies that for any \( \epsilon > 0 \) there are finitely many points \( z_l := e^{it_l} \in \partial \mathbb{D} \), numbers \( s_l \in (0, \pi) \), and constant functions \( f_k^l : \gamma_{t_l}^1(s_l) \rightarrow \mathbb{C}, k \in \{-1, 1\}, 1 \leq l \leq n, \) such that

\[
\bigcup_{l=1}^n (\gamma_{t_l}^{-1}(s_l) \cup \gamma_{t_l}^1(s_l)) = \partial \mathbb{D} \setminus \{z_1, \ldots, z_n\}
\]

and

\[
\text{ess sup}_{z \in \gamma_{t_l}^1(s_l)} |f(z) - f_k^l(z)| < \epsilon, \quad \text{ess sup}_{z \in \gamma_{t_l}^{-1}(s_l)} |f(z) - f_n^l(z)| < \epsilon
\]

for all \( 1 \leq l \leq n \). We set \( U_l := \gamma_{t_l}^{-1}(s_l) \cup \gamma_{t_l}^1(s_l) \cup \{z_l\} \). Then \( U_l := (U_l)^n_{l=1} \) is a finite open cover of \( \partial \mathbb{D} \). Let \( \{\rho_l\}_{l=1}^n \) be a continuous partition of unity subordinate to \( U_l \) and such that \( \text{supp} \rho_l \subset U_l \) and \( \rho_l(z_l) = 1, 1 \leq l \leq n \). Consider the functions \( f_l \) on \( \partial \mathbb{D} \setminus \{z_l\} \) defined by the formulas

\[
f_l(z) := \begin{cases} 
\rho_l(z)f_k^l(z) & \text{if } z \in \gamma_{t_l}^{-1}(s_l), \\
\rho_l(z)f_k^l(z) & \text{if } z \in \gamma_{t_l}^1(s_l).
\end{cases}
\]

If \( z_l \in S \), then \( f_l \in R_{\{z_l\}} \) by definition. If \( z_l \notin S \), then, since \( f \) is continuous outside the compact set \( S \), we can choose the above cover \( U \) and the family of functions \( \{f_k^l\}_{1 \leq k \leq n}, k \in \{-1, 1\} \), so that in \( U_l \) the two functions \( f_k^l, k \in \{-1, 1\} \), have the same limit at \( z_l \). This implies the continuity of \( f_l \) on \( \partial \mathbb{D} \), i.e., \( f_l \in R_{\{z_l\}} \). Also, we have

\[
\|f - \sum_{l=1}^n f_l\|_{L^\infty(\partial \mathbb{D})} < \epsilon.
\]

This completes the proof of the lemma. \( \square \)
Let $F_1 \subset F_2$ be finite subsets of $S$. Then we have the natural injection $i_{F_1,F_2} : R_{F_1} \hookrightarrow R_{F_2}$. Passing to the dual map to $i_{F_1,F_2}$, we obtain a continuous map $p_{F_1,F_2} : \mathcal{M}(R_{F_2}) \to \mathcal{M}(R_{F_1})$ of the corresponding maximal ideal spaces. Now the family $\{(\mathcal{M}(R_{F_1}), \mathcal{M}(R_{F_2}), p_{F_1,F_2})\}_{F_1 \subset F_2 \subset S}$ determines an inverse limit system whose limit coincides with $\mathcal{M}(R_S)$ by Lemma~\ref{lemma:inverse_limit}. By $p_F : \mathcal{M}(R_S) \to \mathcal{M}(R_F)$, where $F \subset S$ is finite, we denote the limit maps determined by this limit. Then

$$c_F \circ p_F = c_S.$$ 

Suppose $F$ consists of $n$ points. Then $\partial \mathbb{D} \setminus F$ is a disjoint union of open arcs $\gamma_k$, $1 \leq k \leq n$. Consider a real function $g_F$ on $\partial \mathbb{D}$ that has discontinuities of the first kind at points of $F$, is continuous outside $F$, and is such that $g_F : \partial \mathbb{D} \setminus F \to \mathbb{R}$ is an injection and $g_F(\partial \mathbb{D} \setminus F)$ is the union of open intervals whose closures are mutually disjoint. Then an argument similar to that in the proof of Theorem~\ref{theorem:main} (see the case of $z_i \notin S$ there) shows that $R_F = \mathbb{C}(g_F)$, the uniform algebra in $L^\infty(\partial \mathbb{D})$ generated by $g_F$. This implies that $\mathcal{M}(R_F)$ is naturally homeomorphic to the disjoint union of the closures $\overline{\gamma_k}$ of $\gamma_k$, $1 \leq k \leq n$, and $c_F : \mathcal{M}(R_F) \to \partial \mathbb{D}$ maps each $\gamma_k$ in this union identically to $\gamma_k \subset \partial \mathbb{D}$.

Since $c_F$ is continuous, for every $z \in F$ the preimage $c_F^{-1}(z)$ consists of two points $z_+$ and $z_-$ that can be identified naturally with the counterclockwise and clockwise orientations of $\partial \mathbb{D}$ at $z$. Thus, we obtain proofs of statements (1)–(3) of the theorem for a finite subset $F \subset S$. To prove the general case, we use \ref{equation:inverse_limit}. Assume that for some $z \in \partial \mathbb{D}$ the preimage $c_S^{-1}(z)$ contains at least three points $x_1$, $x_2$, and $x_3$. Then, by the definition of the inverse limit, there is a finite subset $F \subset S$ such that $p_F(x_1)$, $p_F(x_2)$, and $p_F(x_3)$ are distinct points in $\mathcal{M}(R_F)$. Since by \ref{equation:inverse_limit} the images of these points under $c_F$ coincide with $z$, the case settled above for $\mathcal{M}(R_F)$ shows that $c_F^{-1}(z)$ consists of at most two points, a contradiction. Thus, $c_S^{-1}(z)$ consists of at most two points for every $z \in \partial \mathbb{D}$.

Now, assume that $z \in S$. Let $F \subset S$ be a finite subset containing $z$. Then the preimage $c_F^{-1}(z)$ consists of two points. Since $c_S^{-1}(z) = p_F^{-1}(c_F^{-1}(z))$ by \ref{equation:inverse_limit}, the preimage $c_S^{-1}(z)$ also consists of two points. (As before, they can be identified naturally with the counterclockwise and clockwise orientations of $\partial \mathbb{D}$ at $z$.)

This proves statement (1) of the theorem.

Next, $c_S^{-1}(z)$ is a single point for $z \notin S$. (Otherwise, for some finite $F$ the set $c_F^{-1}(z)$ consists of at least two points, a contradiction.) Since $c_S^{-1}(S)$ is compact, the latter implies that $c_S : \mathcal{M}(R_S) \setminus c_S^{-1}(S) \to \partial \mathbb{D} \setminus S$ is a homeomorphism.

The proof of statement (2) is complete.

To prove (3), we assume that $S$ is infinite (for finite $S$ the statement has already been proved). Let $F \subset S$ be a finite subset consisting of $n$ points, $n \geq 2$. Let $\partial \mathbb{D} \setminus F$ be the disjoint union of open arcs $\gamma_k$, $1 \leq k \leq n$. Let $\chi_{\gamma_k}$ denote the characteristic function of $\gamma_k$. Then every $\chi_{\gamma_k}$ belongs to $R_F$. The same symbols will denote the continuous extensions of $\chi_{\gamma_k}$ to $\mathcal{M}(R_F)$ via the Gelfand transformation. We define a continuous map $K_F : \mathcal{M}(R_F) \to \mathbb{Z}_2(F) := \{0, 1\}^n$ by the formula

$$K_F(m) := (\chi_{\gamma_1}(m), \ldots, \chi_{\gamma_n}(m)), \quad m \in \mathcal{M}(R_F).$$

Setting $Z(S) := \prod_{F \subset S} \mathbb{Z}_2(F)$, we introduce a map $K_S : \mathcal{M}(R_S) \to Z(S)$ by the formula

$$K_S(m) := \{K_F(p_F(m))\}_{F \subset S}.$$ 

We equip $Z(S)$ with the Tychonoff topology. Then $Z(S)$ is a totally disconnected compact Hausdorff space, and the map $K_S$ is continuous.

We show that $K_S|_{c_S^{-1}(S)} : c_S^{-1}(S) \to Z(S)$ is an injection. Indeed, for distinct points $x, y$ in $c_S^{-1}(S)$ there exists a finite subset $F \subset S$ consisting of at least two points and
such that \( p_F(x) \neq p_F(y) \) and \( p_F(x), p_F(y) \in c_F^{-1}(F) \). Then, by the definition of the map \( K_F \), we have

\[
K_F(p_F(x)) \neq K_F(p_F(y)).
\]

This implies that \( K_S(x) \neq K_S(y) \). Since \( c_S^{-1}(S) \) is a compact set, injectivity implies that \( c_S^{-1}(S) \) is homeomorphic to \( K_S \). The latter space is totally disconnected, being a compact subset of the totally disconnected space \( Z(S) \).

This completes the proof of (3).

(4) In accordance with (3), the maximal ideal space \( \mathcal{M}(\text{SAP}(S)) \) of the algebra \( \text{SAP}(S) \) is homeomorphic to the inverse limit of the compact spaces \( \mathcal{M}(\text{SAP}(F)) \) with \( F \subseteq S \) finite. Let \( \tilde{\rho}_{F_1 F_2} : \mathcal{M}(\text{SAP}(F_2)) \to \mathcal{M}(\text{SAP}(F_1)) \), \( F_1 \subseteq F_2 \), be continuous maps determining this limit, and let \( \tilde{\rho}_F : \mathcal{M}(\text{SAP}(S)) \to \mathcal{M}(\text{SAP}(F)) \) be the corresponding limit maps. Since each \( \text{SAP}(F) \) is a selfadjoint algebra, \( \partial \mathbb{D} \setminus F \) is dense in \( \mathcal{M}(\text{SAP}(F)) \) by the Stone–Weierstrass theorem. Hence, \( \tilde{\rho}_{F_1 F_2} \) and \( \tilde{\rho}_F \) are surjective maps.

We begin with the description of \( \mathcal{M}(\text{SAP}(F)) \). Suppose that \( F := \{z_1, \ldots, z_n\} \) and \( F_i := F \setminus \{z_i\} \), \( 1 \leq i \leq n \). Consider the disjoint union

\[
X = \bigsqcup_{1 \leq i \leq n} (\mathcal{M}(\text{SAP}(\{z_i\})) \setminus F_i).
\]

Note that each component of \( X \) contains \( \partial \mathbb{D} \setminus F \) as an open subset. By \( h_i : \partial \mathbb{D} \setminus F \to \mathcal{M}(\text{SAP}(\{z_i\})) \setminus F_i \) we denote the corresponding embeddings. Then for each \( z \in \partial \mathbb{D} \setminus F \) we sew together the points \( h_i(z) \), \( 1 \leq i \leq n \), and identify the resulting point with \( z \). As a result, we obtain a quotient space \( \tilde{X} \) of \( X \) and a “sewing” map \( \pi : X \to \tilde{X} \). We equip \( \tilde{X} \) with the quotient topology:

\[
U \subset \tilde{X} \text{ is open } \iff \pi^{-1}(U) \subset X \text{ is open}.
\]

**Lemma 3.2.** \( \tilde{X} \) is homeomorphic to \( \mathcal{M}(\text{SAP}(F)) \).

**Proof.** By definition, each \( V_i := \pi(\mathcal{M}(\text{SAP}(\{z_i\})) \setminus F_i) \) is an open subset of \( \tilde{X} \) homeomorphic to \( \mathcal{M}(\text{SAP}(\{z_i\})) \setminus F_i \). Since the latter spaces are Hausdorff, \( \tilde{X} \) is also Hausdorff. We cover \( \partial \mathbb{D} \) by closed arcs \( \gamma_1, \ldots, \gamma_n \) such that \( \gamma_i \cap F = \{z_i\} \), \( 1 \leq i \leq n \), and denote by \( \tilde{\gamma}_i \) the closure of \( \gamma_i \) in \( \mathcal{M}(\text{SAP}(\{z_i\})) \). Then \( \tilde{\gamma}_i \) is a compact subset of \( \mathcal{M}(\text{SAP}(\{z_i\})) \setminus F_i \), and \( U_i := \pi(\tilde{\gamma}_i) \) is a compact subset of \( V_i \). It is easily seen that \( \tilde{X} = \bigcup_{1 \leq i \leq n} U_i \). Thus, \( \tilde{X} \) is a compact space. Next, by (3), each function in \( \text{SAP}(F) \) extends continuously to \( \tilde{X} \), and the algebra of these extensions separates points on \( \tilde{X} \). Hence, \( \tilde{X} \) is homeomorphic to \( \mathcal{M}(\text{SAP}(F)) \) by the Stone–Weierstrass theorem.

As a consequence of the above construction, we immediately obtain the following statement.

Let \( F_1 \subseteq F_2 \) be finite subsets of \( S \). Consider the commutative diagram

\[
\begin{array}{cccc}
\mathcal{M}(\text{SAP}(S)) & \xrightarrow{r_S} & \mathcal{M}(R_S) & \xrightarrow{c_S} \partial \mathbb{D} \\
\rho_{F_2} \downarrow & & \rho_{F_2} \downarrow & \\
\mathcal{M}(\text{SAP}(F_2)) & \xrightarrow{r_{F_2}} & \mathcal{M}(R_{F_2}) & \xrightarrow{c_{F_2}} \partial \mathbb{D} \\
\rho_{F_1 F_2} \downarrow & & \rho_{F_1 F_2} \downarrow & \\
\mathcal{M}(\text{SAP}(F_1)) & \xrightarrow{r_{F_1}} & \mathcal{M}(R_{F_1}) & \xrightarrow{c_{F_1}} \partial \mathbb{D}.
\end{array}
\]

(3.4)

Here \( \rho_{F_1 F_2} := \tilde{\rho}_{F_1 F_2} \circ \rho_{F_2} \) and \( \rho_{F_r} := \rho_{F_r} \circ \rho_{F_2} \). We set \( \tilde{F}_1 := (c_{F_1} \circ r_{F_1})^{-1}(F_1) \) and \( \tilde{S}_i := (c_{F_i} \circ r_{F_1})^{-1}(S) \), \( i = 1, 2 \). Then

(A) \( \tilde{\rho}_{F_1 F_2} : \rho_{F_1 F_2}^{-1}(\tilde{F}_1) \to \tilde{F}_1 \) is a homeomorphism; and

(B) \( \mathcal{M}(\text{SAP}(F_2)) \setminus \tilde{S}_2 \xrightarrow{\tilde{\rho}_{F_1 F_2}} \mathcal{M}(\text{SAP}(F_1)) \setminus \tilde{S}_1 \xrightarrow{c_{F_1} \circ r_{F_1}} \partial \mathbb{D} \setminus S \) are the identity maps.
Recalling the definition of the inverse limit, we see that

(A1) \( \tilde{p}_{F_1} : \tilde{p}_{F_1}^{-1}(F_1) \rightarrow F_1 \) is a homeomorphism; and

(B1) \( \mathcal{M}(\text{SAP}(S)) \setminus (c_S \circ r_S)^{-1}(S) \)
\( \tilde{p}_{F_1}^{-1} \mathcal{M}(\text{SAP}(F_1)) \setminus S_1 \) \( \tilde{c}_{P_{F_1}^{-1}} \partial \mathbb{D} \setminus S \) are the identity maps.

Now, assume that \( F_1 = \{ z \} \subset S \). Then, by Theorem 1.5(1), the set \( c_{F_1}^{-1}(F_1) = c_{c_{S}}^{-1}(F_1) \) consists of two points \( \{ z_+ \} \) and \( \{ z_- \} \) identified with the counterclockwise and clockwise orientations at \( z \). Thus, to prove (4) we must show (by (3.4) and statements (A), (A1)) that each set \( \tilde{r}_{(z_1)}^{-1}(z_\pm) \) is homeomorphic to \( b\mathbb{R} \).

For this, we recall that in the proof of Theorem 1.5 we established that \( \mathcal{M}(\text{SAP}(\{ z \})) \)
the inverse limit of the maximal ideal spaces \( \mathcal{M}_{(z)}(s) \) of the algebras \( \text{SAP}_{(z)}(S) \) of continuous functions on \( \partial \mathbb{D} \setminus \{ z \} \) almost periodic on the open arcs \( \gamma_{t}(s) \), where \( z := e^{it} \) and \( s \in (0, \pi) \). Also in that proof, the structure of each \( \mathcal{M}_{(z)}(s) \) was described.

For every pair \( 0 < s' < s' < \pi \), let \( p_{s'\theta} : \mathcal{M}_{(z)}(s') \rightarrow \mathcal{M}_{(z)}(s') \) be the continuous surjective map dual to the embedding \( \iota_{s',s'} : \text{SAP}_{(z)}(s') \hookrightarrow \text{SAP}_{(z)}(s') \). From the proof of Theorem 1.5 we know that every \( \mathcal{M}_{(z)}(s) \) is obtained by gluing \( \partial \mathbb{D} \setminus \{ z \} \) with two copies of \( b\mathbb{R} \), where one copy (denoted by \( b\mathbb{R}_1 \)) is obtained by gluing with \( \gamma_{t}(s) \) and another copy (denoted by \( b\mathbb{R}_{-1} \)) is obtained by gluing with \( \gamma_{1-t}(s) \). Suppose that \( z \in \mathbb{R} \setminus \mathcal{M}_{(z)}(s') \). We compute \( p_{s'\theta}(\xi) \in b\mathbb{R}_1 \setminus \mathcal{M}_{(z)}(s') \). Let \( \{ z_\pm \} \subset \gamma_{t}(s') \) be a net converging to \( z \). This means that the net \( \{ \phi_{s'}(z_\pm) \} \subset \mathcal{M}_{(z)}(s') \) converges to \( z \) in the topology of the Bohr compactification on \( b\mathbb{R} \); here \( \phi_{s'} \) is the map inverse to the map \( \psi_{s'} : \mathbb{R} \rightarrow \gamma_{t}(s'), \mathbb{R} \rightarrow e^{it} \). Next, by definition, the net \( \{ \phi_{s'}(z_\pm) \} \) converges to \( p_{s'\theta}(\xi) \). A straightforward computation shows that
\( \phi_{s'}(z_\pm) = \phi_{s'}(z_\pm) + \ln \left( \frac{s'}{s} \right) \) for all \( z_\pm \).

Thus, we have
\( p_{s'\theta}(\xi) = \xi + \ln \left( \frac{s'}{s} \right), \quad \xi \in b\mathbb{R}_1. \)
Here the sum refers to the group operation on \( b\mathbb{R} \). Similarly,
\( p_{s'\theta}(\xi) = \xi + \ln \left( \frac{s'}{s} \right), \quad \xi \in b\mathbb{R}_{-1}. \)

Using these formulas, now we prove that each \( r_{(z)}^{-1}(z_\pm) \) is homeomorphic to \( b\mathbb{R} \). We shall prove the statement for \( z_+ \) (for \( z_- \) the argument is similar).

For a fixed \( s_0 \in (0, \pi) \), consider the limit map \( p_{s_0} : \mathcal{M}(\text{SAP}(\{ z \})) \rightarrow \mathcal{M}_{(z)}(s_0) \). Then \( p_{s_0} \) maps \( r_{(z)}^{-1}(z_+) \) into \( X_{s_0} := b\mathbb{R}_1 \subset \mathcal{M}_{(z)}(s_0) \). Moreover, by definition, \( r_{(z)}^{-1}(z_+) \) is the inverse limit of the system \( \{ (X_{s'}(z_+), X_{s'}(p_{s'\theta}), p_{s'\theta} : X_{s'}(z_+) \rightarrow X_{s'}(p_{s'\theta})) \} \), where we write \( X_s \) for \( b\mathbb{R}_1 \subset \mathcal{M}_{(z)}(s) \).
Since, in accordance with (3.4), every \( p_{s'\theta} : X_{s'} \rightarrow X_{s} \) is a homeomorphism (even an automorphism of \( b\mathbb{R} \)), the definition of the inverse limit shows that \( p_{s_0} : r_{(z)}^{-1}(z_+) \rightarrow X_{s_0} \) is a homeomorphism.

This completes the proof of statement (4).
(5) This follows from (B1) and Theorem 1.7 (2).

The proof of Theorem 1.7 is complete. □

Remark 3.3. It is well known that the covering dimension of \( b\mathbb{R} \) is \( \infty \), because this group is the inverse limit of compact Abelian Lie groups whose dimensions tend to \( \infty \). Since \( b\mathbb{R} \subset \mathcal{M}(\text{SAP}(S)) \), the covering dimension of \( \mathcal{M}(\text{SAP}(S)) \) is also infinite (statement (6)). Also, statement (7) follows from the fact that \( c_S^{-1}(S) \) is totally disconnected. Indeed, the image of \( r_S \circ \phi \) is a single point for a continuous map \( \phi : T \rightarrow (c_S \circ r_S)^{-1}(S) \) of a connected topological space \( T \). This implies the claim.
§4. Proofs of Theorem 1.8 and Example 1.10

4.1. In this section we formulate and prove some auxiliary results used in the proof of the theorem.

**Notation.** Let \( z_0 \in \partial \mathbb{D} \), and let \( U_{z_0} \) be the intersection of an open disk of radius not exceeding 1 centered at \( z_0 \) with \( \mathbb{D} \setminus \{ z_0 \} \). We call \( U_{z_0} \) a **circular neighborhood** of \( z_0 \).

Next, we define almost periodic functions continuous on a circular neighborhood \( U_{z_0} \) of \( z_0 \) and holomorphic in the interior of \( U_{z_0} \) as follows.

Let \( \phi_{z_0} : \mathbb{D} \to \mathbb{H}_+ \),

\[
(4.1) \quad \phi_{z_0}(z) := \frac{2i(z_0 - z)}{z_0 + z}, \quad z \in \mathbb{D},
\]

be a conformal map of \( \mathbb{D} \) onto the upper half-plane \( \mathbb{H}_+ \). Then \( \phi_{z_0} \) is continuous on \( \partial \mathbb{D} \setminus \{ -z_0 \} \) and maps this set diffeomorphically onto \( \mathbb{R} \) (the boundary of \( \mathbb{H}_+ \)) so that \( \phi_{z_0}(z_0) = 0 \). Let \( \Sigma_0 \) be the interior of the strip \( \Sigma := \{ z \in \mathbb{C} : \Im z \in [0, \pi] \} \).

Consider the conformal map \( \Log : \mathbb{H}_+ \to \Sigma_0 \), \( z \mapsto \Log(z) := \ln |z| + i \Argument(z) \), where \( \Argument : \mathbb{C} \setminus (-\pi, \pi) \to (-\pi, \pi) \) is the principal branch of the multifunction \( \Argument \), the argument of a complex number. The function \( \Log \) extends to a homeomorphism of \( \mathbb{H}_+ \setminus \{ 0 \} \) onto \( \Sigma \); here \( \mathbb{H}_+ \) stands for the closure of \( \mathbb{H}_+ \).

We denote by \( AP_C(\Sigma) \) the algebra of uniformly continuous almost periodic functions on \( \Sigma \) (i.e., they are almost periodic on any line parallel to the \( x \)-axis). Clearly, we have \( AP_C(\Sigma) \subset AP_C(\Sigma) \). Then, by Theorem 2.3 (the corona theorem for \( AP_C(\Sigma) \)), the maximal ideal space \( \mathcal{M}(AP_C(\Sigma)) \) of the algebra \( AP_C(\Sigma) \) is homeomorphic to \( \mathcal{M}(AP_C(\Sigma)) \).

In what follows we identify these spaces.

**Definition 4.1.** We say that \( f : U_{z_0} \to \mathbb{C} \) is a **(continuous) almost periodic function** if there is a function \( \hat{f} \in AP_C(\Sigma) \) such that

\[
f(z) := \hat{f}(\Log(\phi_{z_0}(z))) \quad \text{for all} \quad z \in U_{z_0}.
\]

If \( \hat{f} \in AP_C(\Sigma) \), then \( f \) is called a **holomorphic almost periodic function**.

Suppose that \( z_0 = e^{it_0} \). For \( s \in (0, \pi) \) we set \( \gamma_1(z_0, s) := \Log(\phi_{z_0}(\gamma_{t_0}^{-1}(s))) \subset \mathbb{R} \) and \( \gamma_{-1}(z_0, s) := \Log(\phi_{z_0}(\gamma_{t_0}^{-1}(s))) \subset \mathbb{R} + i\pi \).

**Lemma 4.2.** Let \( f \in SAP((-\pi, z_0)) \). We set \( f_k := f|_{\gamma_{t_0}^{-1}(\pi)} \) and consider the functions \( h_k = f_k \circ \varphi_{z_0}^{-1} \circ \Log^{-1} \) on \( \gamma_k(z_0, s) \), \( k \in \{-1, 1\} \). Then for any \( \varepsilon > 0 \) there are points \( s_\varepsilon \in (0, s) \) and almost periodic functions \( h'_1 \) on \( \mathbb{R} \) and \( h'_{-1} \) on \( \mathbb{R} + i\pi \) such that

\[
(4.2) \quad \sup_{z \in \gamma_k(z_0, s_\varepsilon)} |h_k(z) - h'_k(z)| < \varepsilon \quad \text{for each} \quad k \in \{-1, 1\}.
\]

**Proof.** We prove the result for \( f_1 \) only. The proof for \( f_{-1} \) is similar. By Theorem 1.5 it suffices to prove the lemma for \( f_1 = g_{t_0} \) or \( f_1 = e^{i\lambda \Log_{t_0}}, \lambda \in \mathbb{R} \). In the first case we can choose a sufficiently small \( s_\varepsilon \) such that on \( \gamma_{t_0}^{-1}(s_\varepsilon) \) the function \( g_{t_0} \) is uniformly approximated with an error less than \( \varepsilon \) by a constant function. Then for the role of \( h'_1 \) we can choose the corresponding constant function on \( \gamma_{t_0}(z_0, s_\varepsilon) \). In the second case, by definition,

\[
h_1(x) = e^{i\lambda \Log(\frac{2ix+1}{2ix-1})} e^{i\lambda \Log(\frac{4\varepsilon x^2 + e^{2\varepsilon}}{4\varepsilon x^2 - e^{2\varepsilon}})} = e^{i\lambda(x + o(e^\varepsilon))} \quad \text{as} \quad x \to -\infty.
\]

This implies that

\[
|h_1(x) - e^{i\lambda x}| < \varepsilon \quad \text{for all} \quad x \in \gamma_{t_0}(z_0, s_\varepsilon)
\]

if \( s_\varepsilon \) is sufficiently small. \( \square \)
Lemma 4.3. Suppose that \( f_1 \) and \( f_2 \) are continuous almost periodic functions on \( \mathbb{R} \) and \( \mathbb{R} + i\pi \), respectively. Then there exists a function \( F \in \text{AP}_c(\Sigma) \) harmonic in \( \Sigma_0 \) whose boundary values are \( f_1 \) and \( f_2 \).

Proof. Let \( F \) be a function harmonic in \( \Sigma_0 \) with boundary values \( f_1 \) and \( f_2 \). Since \( f_1 \) and \( f_2 \) are almost periodic, for any \( \epsilon > 0 \) there exists \( l(\epsilon) > 0 \) such that every interval \([t_0, t_0 + l(\epsilon)]\) contains a common \( \epsilon \)-period of \( f_1 \) and \( f_2 \), say, \( \tau_\epsilon \) (see, e.g., [LZ]). Thus,

\[
\sup_{x \in \mathbb{R}} |f_1(x + \tau_\epsilon) - f_1(x)| < \epsilon \text{ and } \sup_{x \in \mathbb{R}} |f_2(x + i\pi + \tau_\epsilon) - f_2(x + i\pi)| < \epsilon.
\]

Now, by the maximum principle for harmonic functions,

\[
\sup_{x \in \mathbb{R}} |F(x + iy + \tau_\epsilon) - F(x + iy)| < \epsilon \text{ for each } y \in [0, \pi];
\]

that is, \( F \) is almost periodic on every line \( \mathbb{R} + iy, \ y \in [0, \pi] \). \( \square \)

Let \( A(U_{z_0}) \) be the algebra of functions continuous on \( D \) and almost periodic on the circular neighborhood \( U_{z_0} \) of \( z_0 \). Let \( A_{z_0} \) denote the uniform closure of the algebra generated by all \( A(U_{z_0}) \), and let \( M_{z_0} \) be the closure of \( D \) in the maximal ideal space of \( A_{z_0} \). Since the algebra \( A_{z_0} \) is selfadjoint, the Stone-Weierstrass theorem shows that \( M_{z_0} \) coincides with the maximal ideal space of \( A_{z_0} \). Next, let \( p_{z_0} : M_{z_0} \to \mathbb{D} \) be the continuous surjective map dual to the natural embedding \( C(D) \to A_{z_0} \).

Lemma 4.4. (a) For every neighborhood \( U \) of the compact set \( F_{z_0} := p_{z_0}^{-1}(z_0) \), there is a circular neighborhood \( U_{z_0} \) of \( z_0 \) such that \( U_{z_0} \cap D \subset U \cap D \).

(b) \( F_{z_0} \) is homeomorphic to \( M(\text{AP}_c(\Sigma)) \).

(c) Each function \( f \in \text{SAP}(\Sigma) \cap H^\infty \) belongs to the algebra \( \bigcap_{z \in \partial D} A_z \).

Proof. (a), (b). Since the algebra \( A(U_{z_0}) \) is selfadjoint, \( D \) is dense in the maximal ideal space \( M(U_{z_0}) \). Then \( M_{z_0} \) is the inverse limit of the compact spaces \( M(U_{z_0}) \) (because \( A_{z_0} \) is the uniform closure of the algebra generated by the algebras \( A(U_{z_0}) \)); see, e.g., [R].

For \( U_{z_0} \subset V_{z_0} \), we denote by \( p_{U_{z_0} \cap V_{z_0}} : M(U_{z_0}) \to M(V_{z_0}) \) the maps in this limit system and by \( p_{U_{z_0} \cap V_{z_0}} : M_{z_0} \to M(U_{z_0} \cap V_{z_0}) \) the corresponding (continuous and surjective) limit maps.

Then, by the definition of the inverse limit, the base of topology on \( M_{z_0} \) consists of the sets \( p_{U_{z_0} \cap V_{z_0}}^{-1}(U) \), where \( U \subset M(U_{z_0}) \) is open and \( U_{z_0} \) is a circular neighborhood of \( z_0 \). In particular, since \( F_{z_0} \) is a compact set, for a neighborhood \( U \) of \( F_{z_0} \) there is a circular neighborhood \( U_{z_0} \) of \( z_0 \) and a neighborhood \( \bar{U} \subset M(U_{z_0}) \) of \( F(\bar{U}_{z_0}) := p_{U_{z_0}}(F_{z_0}) \) such that \( p_{U_{z_0}}^{-1}(\bar{U}) \subset U \). Recall that \( D \) is a dense subset of \( M(\bar{U}_{z_0}) \) and of \( M_{z_0} \). Also, \( p_{U_{z_0}}^{-1}(D) \) contains \( \bar{U} \subset M(\bar{U}_{z_0}) \). Thus, to prove (a) it suffices to show that there is \( U_{z_0} \subset \bar{U}_{z_0} \) such that \( U_{z_0} \cap D \subset U \cap D \).

First, we study the structure of \( M(\bar{U}_{z_0}) \). Let \( A^*(\bar{U}_{z_0}) \) be the pullback to \( \Sigma \) via the map \( (\log \circ \phi_{z_0})^{-1} \) of the algebra \( A(\bar{U}_{z_0}) \). Then \( A^*(\bar{U}_{z_0}) \) consists of continuous functions on \( \Sigma_0 \) such that on \( (\log \circ \phi_{z_0})(\bar{U}_{z_0}) \) they are restrictions of almost periodic functions on \( \Sigma \). Since \( A^*(\bar{U}_{z_0}) \) is isomorphic to \( A(\bar{U}_{z_0}) \), we can naturally identify the maximal ideal spaces of these algebras.

Next, observe that there is \( T < 0 \) such that \( (\log \circ \phi_{z_0})(\bar{U}_{z_0}) \) contains the subset \( \Sigma_T := \{ z \in \Sigma : \text{Re } z \leq T \} \) of the strip \( \Sigma \). By the definition of the topology on \( M(\text{AP}_c(\Sigma)) \) (see §2), \( \Sigma_T \) is dense in \( M(\text{AP}_c(\Sigma)) \). Hence, the space \( M(\bar{U}_{z_0}) \) contains \( M(\text{AP}_c(\Sigma)) (= M(\text{AP}_c(\Sigma))) \). Let \( K \) be the intersection of the closures of \( \bar{U}_{z_0} \) and of \( \mathbb{D} \setminus \bar{U}_{z_0} \) in \( C \). Then \( K' := \log \circ \phi_{z_0}(K) \) is a compact subset of \( \Sigma \). In particular,
APe(Σ)|_{K'} = C(K'). This implies (by the Tietze extension theorem) that every bounded continuous function on (D \ \setminus \ \bar{U}_z) \cup K can be extended to a function of class A(\bar{U}_z) with the same supremum norm. Now, we can describe M(\bar{U}_z) explicitly as follows (cf. the proof of Theorem 4.5 for a similar construction).

Let M be the maximal ideal space of the algebra of bounded continuous functions on (D \ \setminus \ \bar{U}_z) \cup K. We identify K \subseteq M with K' \subset M(APe(Σ)) with the help of Log o \phi_0. Under this identification, the quotient space of M \cup M(APe(Σ)) is homeomorphic to M(\bar{U}_z).

By definition, the fiber F_{\bar{z}} over \bar{z} consists of the limit points in M(\bar{z}) of all nets converging to \{z_0\} inside D. This and the above construction of M(\bar{U}_z) show that F(\bar{U}_z) is homeomorphic to M(APe(Σ)). Moreover, F_{\bar{z}} is the inverse limit of the compact sets F(\bar{U}_z), where the limit system is determined by the maps p_{\bar{z}}U_{z_0}|_{\{F(U_{z_0})\}} for U_{z_0} \subset V_{z_0}. We show that the maps p_{\bar{z}}U_{z_0}|_{\{F(U_{z_0})\}} → F(V_{z_0}) are homeomorphisms. Indeed, let \{z_{\alpha}\} ⊂ U_{z_0} be a net converging to a point ξ ∈ F(U_{z_0}). Since U_{z_0} → V_{z_0}, in our definitions of M(U_{z_0}) and M(V_{z_0}), the net \{z_{\alpha}\} converges to the same point ξ ∈ F(V_{z_0}), which gives the required statement. Since all maps p_{\bar{z}}U_{z_0}|_{\{F(U_{z_0})\}} are homeomorphisms, the definition of the inverse limit implies that the map p_{\bar{z}}U_{z_0}|_{F_{\bar{z}}} : F_{\bar{z}} → F(\bar{U}_z) is also a homeomorphism. This completes the proof of (b).

Now, observe that in our model of M(\bar{U}_z) the intersection of \bar{U} with D contains \bar{U}_z ∩ D, which completes the proof of (a).

(c) Fix a point z_0 ∈ ∂D. We must show that every f ∈ SAP(S) ∩ H^∞ belongs to A_{z_0}. By 3.2 and Lemma 4.2 each f ∈ SAP(∂D) ∩ H^∞ can be approximated locally on open arcs of the form γ_{k,l}(s), k ∈ \{-1,1\}, s ∈ (0, π), \gamma := e^{it} ∈ ∂D, by pullbacks of almost periodic functions on the boundary of Σ. Using the compactness of ∂D, for any ϵ > 0 we can find finitely many points z_1, ..., z_n ∈ ∂D, arcs γ_{k,l}(s_k), k ∈ \{-1,1\}, s_k ∈ (0, π), z_l := e^{i\theta_l}, and functions f_l : ∂D \ \setminus \ \{-z_l, z_l\} → C which are pullbacks of almost periodic functions on ∂Σ by means of Log o \phi_{z_l}, 1 ≤ l ≤ n, such that

\[ \text{ess sup}_{\gamma_{k,l}(s_k) \cup \gamma_{k,l}(s_k)} |f(z) - f_l(z)| < \epsilon \]

for all 1 ≤ l ≤ n. Without loss of generality, we may assume that z_0 ∈ \{z_1, ..., z_n\}. Next, set V_l := γ_{k,l} \cup γ_{k,l} \cup \{z_l\}. Then \( (V_l)_{l=1}^n \) is a finite open cover of ∂D. Let \( \rho_l \)_{l=1}^n be a smooth partition of unity subordinate to this cover and such that \( \rho_l(z_l) = 1 \). Consider the functions f_l on ∂D \ \setminus \ \{z_l\} defined by the formulas

\[ f_l := \rho_l f_l, \quad 1 ≤ l ≤ n. \]

Let F be the harmonic function on D such that \( F|_{∂D} = \sum_{1≤l≤n} f_l. \) Then

\[ \|F - F\|_{L^\infty(D)} < \epsilon. \]

We prove that F ∈ A_{z_0}. Since ϵ > 0 is arbitrary, this will complete the proof of (c).

Let F_{1,l} and F_{1,2} be the harmonic functions on D with the boundary values f_1 and \( f_l - f_1 \), respectively. Then F_1 := F_{1,1} + F_{1,2} is the harmonic function with the boundary values f_1. By Lemma 4.3 every F_1 is almost periodic on D \ \setminus \ \{±z_l\}. Thus, if z_l = z_0, then F_1 ∈ A_{z_0}. If z_l ≠ z_0, then F_1 is continuous at z_0, and so F_1 ∈ A_{z_0}. Next, for a point z_0 distinct from z_0, the function F_{1,1} extends continuously to an open disk centered at z_0 (because the support of f_1 does not contain z_0). Hence, F_{1,1} ∈ A_{z_0}. Assume now that z_l = z_0 for some l. Then the function F_{1,2} extends continuously to
an open disk centered at $z_*$ (because the support of $f^l - f_1$ does not contain $z_*$). Thus, $F_{l,2} \in \mathcal{A}_{z_*}$, and in this case, $F_{l,1} := F_l - F_{l,2} \in \mathcal{A}_{z_*}$. Since $F := \sum_{1 \leq l \leq n} F_{l,1}$, combining the cases considered above, we see that $F \in \mathcal{A}_{z_*}$.

This completes the proof of Lemma 4.3.

**Theorem 4.5.** Let $f \in \text{SAP}(S) \cap H^\infty$. Then for each $z_0 \in \partial D$ and any $\epsilon > 0$ there is a circular neighborhood $U_{z_0} := U_{z_0}(f, \epsilon)$ of $z_0$ and a holomorphic almost periodic function $f_{z_0}$ on $U_{z_0}$ such that

$$
\sup_{z \in U_{z_0}} |f(z) - f_{z_0}(z)| < \epsilon.
$$

**Proof.** Fix a point $z_0 \in \partial D$. By Lemma 4.3(c), the function $f \in \text{SAP}(S) \cap H^\infty$ belongs to $\mathcal{A}_{z_0}$, so that it extends via the Gelfand transformation up to a continuous function $\tilde{f}$ on $\mathcal{M}_{z_0}$. We use the description of $\mathcal{M}_{z_0}$ presented in the proof of Lemma 4.4. Recall that in that construction the fiber $F_{z_0} \subset \mathcal{M}_{z_0}$ over $z_0$ is identified naturally with $\mathcal{M}(\text{AP}_\Sigma(\Sigma))$.

**Lemma 4.6.** The function $\tilde{f}|_{F_{z_0}}$ is holomorphic.

**Proof.** In the proof we use the results of §2. Consider the map $i_\xi : \Sigma_0 \to \mathcal{M}(\text{AP}_\Sigma(\Sigma))$, $\xi \in b\mathbb{Z}$. We must show that $\tilde{f} \circ i_\xi$ is holomorphic.

For this, we transfer the function $f$ with the help of the map $(\log \circ \phi_{z_0})^{-1}$ to $\Sigma_0$ and denote by $\tilde{f}$ the function pulled back. Fix a point $\eta \in i_\xi(\Sigma_0)$, say, $\eta := i_\xi(w)$, $w \in \Sigma_0$. Then there is a straight line $\mathbb{R} + iy \subset \Sigma_0$, $y \in (0, \pi)$, and a net $\{z_0\} \subset \mathbb{R} + iy$ forming an infinite discrete subset of $\mathbb{R} + iy$ such that $\{z_0\}$ converges to $\eta$ in the topology of $\mathcal{M}(\text{AP}_\Sigma(\Sigma))$. Let $B \subset \mathbb{C}$ be an open disk such that $\{\mathbb{R} + iy\} + B \subset \Sigma_0$. By the definition of $i_\xi$, for each $z \in B$ the net $\{z_0 + z\}$ converges in $\mathcal{M}(\text{AP}_\Sigma(\Sigma))$ to $i_\xi(w + z)$. Also, by the definition of $\mathcal{M}_{z_0}$, we have

$$
\lim_{\alpha} \tilde{f}(z_0 + z) = (\tilde{f} \circ i_\xi)(w + z), \quad z \in B.
$$

But the holomorphic functions $\tilde{f}_\alpha(z) := \tilde{f}(z_0 + z)$ form a normal family on $B$. Therefore, using an argument similar to that in the proof of Lemma 2.3(1), we see that $\tilde{f} \circ i_\xi|_B$ is holomorphic. Since $\xi$ and $\eta$ are arbitrary, this implies that $\tilde{f}|_{F_{z_0}}$ is holomorphic.  

Now, Lemma 2.3 shows the existence of a function $\tilde{f}_{z_0} \in AP_\Sigma$ whose extension to $\mathcal{M}(\text{AP}_\Sigma(\Sigma))$ coincides with $\tilde{f}|_{F_{z_0}}$. Consider the function $f_{z_0} \in \mathcal{A}_{z_0}$ whose pullback to $\Sigma$ via $(\log \circ \phi_{z_0})^{-1}$ coincides with $\tilde{f}_{z_0}$. Then, by the definition of the topology of $\mathcal{M}_{z_0}$, the extension $\tilde{f}_{z_0}$ of $f_{z_0}$ to $\mathcal{M}_{z_0}$ satisfies $\tilde{f}_{z_0}|_{F_{z_0}} = \tilde{f}|_{F_{z_0}}$. Since $F_{z_0}$ is a compact set, the latter implies that there is a neighborhood $U$ of $F_{z_0}$ in $\mathcal{M}_{z_0}$ such that $|\tilde{f}_{z_0}(x) - \tilde{f}(x)| < \epsilon$ for all $x \in U$. Finally, by Lemma 4.4(a), there is a circular neighborhood $U_{z_0}$ such that $U_{z_0} \cap D \subset U \cap D$, whence $|f_{z_0}(z) - f(z)| < \epsilon$ for all $z \in U_{z_0} \cap D$.

**4.2. Proof of Theorem 1.8.** We must show that $A_S = \text{SAP}(S) \cap H^\infty$. We split the proof into several parts. First, we prove the following statement.

**Lemma 4.7.** \(\text{SAP}(S) \cap H^\infty\) is the uniform closure of the algebra generated by all possible subalgebras \(\text{SAP}(F) \cap H^\infty\) with finite \(F \subset S\).

Then we shall prove that $A_S = \text{SAP}(F) \cap H^\infty$ for every finite subset $F \subset \partial D$. Combined with the above lemma and the fact that $A_S$ is the uniform closure of the algebra generated by all possible subalgebras $A_F$ with finite $F \subset S$, this will clearly complete the proof of the theorem.
Proof. By Theorem 4.5, for a given \( f \in \text{SAP}(S) \cap H^\infty \) we can find finitely many points \( z_1, \ldots, z_n \), circular neighborhoods \( U_{z_1}, \ldots, U_{z_n} \), and holomorphic almost periodic functions \( f_1, \ldots, f_n \) defined on \( U_{z_1}, \ldots, U_{z_n} \), respectively, such that \( (U_{z_i})_{1 \leq i \leq n} \) forms an open cover of \( \partial \mathbb{D} \setminus \{ z_1, \ldots, z_n \} \) and

\[
\max_i \| f|_{\partial U_{z_i}} - f_i \|_{L^\infty(U_{z_i})} < \epsilon.
\]

Since the discontinuities of \( f|_{\partial \mathbb{D}} \) belong to the closed set \( S \), each function \( f_i \) with \( z_i \notin S \) can be chosen also to be continuous on the closure \( \overline{U_{z_i}} \).

Next, we form a cocycle \( \{ c_{ij} \} \) on the intersections of sets from the above cover by the formula

\[
c_{ij}(z) := f_i(z) - f_j(z), \quad z \in U_{z_i} \cap U_{z_j}.
\]

Reducing, if necessary, the sets of the above cover, we may assume without loss of generality that all \( U_{z_i} \cap U_{z_j}, i \neq j \), do not contain the points \( z_1, \ldots, z_n \). Then each \( U_{z_i} \cap U_{z_j}, i \neq j \), is a compact subset of \( \mathbb{D} \), and the corresponding \( c_{ij} \) are continuous and holomorphic in the interior of \( U_{z_i} \cap U_{z_j} \).

Let \( \{ p_i \} \) be a smooth partition of unity subordinate to the cover \( (U_{z_i})_{1 \leq i \leq n} \). We can require that every \( p_i \) be the restriction to \( \overline{U_{z_i}} \) of a \( C^\infty \)-function on \( \mathbb{C} \) and that \( p_i(z_i) = 1 \).

As usual, we employ this partition of unity to resolve the cocycle \( \{ c_{ij} \} \) by the formulas

\[
(4.3) \quad \tilde{f}_j(z) = \sum_{k=1}^n p_k(z)c_{jk}(z), \quad z \in \overline{U_{z_j}}.
\]

Hence,

\[
c_{ij}(z) := \tilde{f}_i(z) - \tilde{f}_j(z), \quad z \in U_{z_i} \cap U_{z_j}.
\]

In particular, since the \( c_{ij} \) are holomorphic in \( \mathbb{D} \cap U_{z_i} \cup U_{z_j} \), the formula

\[
h(z) := \frac{\partial \tilde{f}_i(z)}{\partial \zeta}, \quad z \in U_{z_i} \cap \mathbb{D},
\]

determines a smooth bounded function in an open annulus \( A \subset \bigcup_{i=1}^n \overline{U_{z_i}} \) with the outer boundary \( \partial \mathbb{D} \). Also, by our choice of the partition of unity, \( h \) extends continuously to the closure \( \overline{A} \) of \( A \).

Consider the function

\[
(4.4) \quad H(z) = \frac{1}{2\pi i} \int_{\zeta \in A} \frac{h(\zeta)}{\zeta - z} \, d\zeta \wedge d\overline{\zeta}, \quad z \in \overline{A}.
\]

Passing in \( (4.4) \) to polar coordinates with origin at \( z \), we easily obtain

\[
(4.5) \quad \sup_{z \in A} |H(z)| \leq C w(A) \sup_{z \in A} |h(z)|,
\]

where \( w(A) \) is the width of \( A \) and \( C > 0 \) is an absolute constant. Moreover, \( H \in C(\overline{A}) \) and \( \partial H/\partial \zeta = h \) in \( A \) (see, e.g., [3] Chapter VIII). We can replace \( A \) by a similar annulus of a smaller width such that for this new \( A \),

\[
\sup_{z \in A} |H(z)| < \epsilon.
\]

Now, we set

\[
c_i(z) := \tilde{f}_i(z) - H(z), \quad z \in U_{z_i} \cap \overline{A}.
\]

Then each \( c_i \) is continuous on \( U_{z_i} \cap \overline{A} \) and holomorphic at the interior points of this set, and

\[
c_i(z) - c_j(z) = c_{ij}(z), \quad z \in U_{z_i} \cap U_{z_j}.
\]

Since \( |c_{ij}(z)| < 2\epsilon \) for all \( z \in U_{z_i} \cap U_{z_j} \), we have

\[
|c_i(z)| < 3\epsilon, \quad z \in U_{z_i} \cap U_{z_j}.
\]
We define a global function $f_\epsilon$ on $\overline{A} \setminus \{z_1, \ldots, z_n\}$ by the formulas
\[ f_\epsilon(z) := f_i(z) - c_i(z), \quad z \in U_i \cap \overline{A}. \]
Since for $z_1 \notin S$ the function $f_i$ is continuous on $\overline{U}_z$, the above construction shows that $f_\epsilon \in H^\infty(A) \cap \text{SAP}(F)$, where $F := \{z_1, \ldots, z_n\} \cap S$. Also,
\[ \|f - f_\epsilon\|_{L^\infty(A)} < 4\epsilon. \]
Let $B$ be an open disk centered at 0 whose intersection with $A$ is an annulus of width less than $\epsilon$. Consider the cocycle $c$ on $B \cap A$ defined by
\[ c(z) = f(z) - f_i(z), \quad z \in B \cap A. \]
By definition, $|c(z)| \leq 4\epsilon$ for all $z \in B \cap A$. Let $A'$ be the open annulus with the interior boundary coinciding with the interior boundary of $A$ and with the outer boundary \( \{z \in \mathbb{C} : |z| = 2\} \). Then $A' \cap B = A \cap B$. Consider a smooth partition of unity subordinate to the cover $\{A', B\}$ of $D$ and consisting of smooth radial functions $\rho_1$ and $\rho_2$ such that
\[ \max_i \|\nabla \rho_i\|_{L^\infty(C)} \leq C w(B \cap A) < \tilde{C} \epsilon \]
for some absolute constant $\tilde{C} > 0$. Then using similar arguments to the above and based on versions of (4.3), (4.4), and (4.5) for the cocycle $c$ and the partition of unity $\{\rho_1, \rho_2\}$, we can find holomorphic functions $\overline{\kappa}_1$ on $B$ and $\overline{\kappa}_2$ on $A$ continuous on the corresponding boundaries and such that $\overline{\kappa}_1(z) - \overline{\kappa}_2(z) = c(z)$, $z \in B \cap A$, and
\[ \max\{|\overline{\kappa}_1|_{H^\infty(B)}, |\overline{\kappa}_2|_{H^\infty(A)}\} \leq \overline{C} \|c\|_{H^\infty(A \cap B)}, \]
where $\overline{C} > 0$ is an absolute constant. Finally, we define
\[ F_\epsilon(z) := \begin{cases} f(z) - \overline{\kappa}_1(z) & \text{if } z \in B, \\ f_\epsilon(z) - \overline{\kappa}_2(z) & \text{if } z \in D \setminus B. \end{cases} \]
Clearly,
\[ \|f - F_\epsilon\|_{L^\infty(D)} < \epsilon \]
for some absolute constant $\epsilon > 0$, and $F_\epsilon \in \text{SAP}(F) \cap H^\infty$, where $F := \{z_1, \ldots, z_n\} \cap S$. Since $\epsilon$ is arbitrary, this completes the proof of the lemma.

As the next step of the proof we establish Theorem 1.8 for $\text{SAP}(F) \cap H^\infty$ with a finite set $F \subset \partial S$, say, $F = \{z_1, \ldots, z_n\}$.

**Lemma 4.8.**
\[ A_F = \text{SAP}(F) \cap H^\infty. \]

**Proof.** We show that $\text{SAP}(F) \cap H^\infty \subset A_F$. First, suppose that $F$ contains at least two points.

Let $\psi_1 : \partial \mathbb{D} \to \partial \mathbb{D}$ be the restriction to the boundary of a Möbius transformation of $\mathbb{D}$ that maps $-z_1$ to a point of $F$ distinct from $z_1$ and preserves $z_1$. Then, by the definition of the Möbius transformations, $\psi_1$ is a $C^1$ diffeomorphism of $\partial \mathbb{D}$. In particular, by Corollary 1.6 for any $f \in \text{SAP}(F) \cap H^\infty$ we have $f \circ \psi_1 \in \text{SAP}(F_1) \cap H^\infty$, where $F_1 := \psi_1^{-1}(F)$. Since $z_1 \in F_1$, we can argue as in the proof of Theorem 1.5 to find an almost periodic holomorphic function $g_1$ on $\overline{\mathbb{D} \setminus \{\pm z_1\}}$ such that the function $f \circ \psi_1 - g_1$ is continuous and equals 0 at $z_1$. We set
\[ g_1(z) := \frac{g(z)(z + z_1)}{2z_1}, \quad z \in \overline{\mathbb{D} \setminus \{z_1\}}. \]
Then $g_1$ has a discontinuity at $z_1$ only. We show that $g_1 \in A_{\{-z_1,z_1\}}$. Indeed, the definition of $g_1$ implies that the function $g_1 \circ \phi_{z_1}^{-1} \circ \text{Log}^{-1}$ belongs to $A_{\overline{D}(\Sigma)}$. Therefore,
it can be uniformly approximated on $\Sigma$ by polynomials in the variables $e^{i\lambda z}, \lambda \in \mathbb{R}$; see, e.g., [11]. In its turn, $g_1$ can be uniformly approximated on $\mathbb{D} \setminus \{\pm 1\}$ by complex polynomials in the variables $e^{i\lambda \log \circ \phi_1}$. Now, for $z \in \partial \mathbb{D}$ we have

$$\text{Im}(\{(\log \circ \phi_2)\}(z)) := \begin{cases} 0 & \text{if } 0 \leq \text{Arg}(z/z_1) < \pi, \\ \pi & \text{if } 0 \leq \text{Arg}(z_1/z) < \pi. \end{cases}$$

This implies that every function $e^{i\lambda \log \circ \phi_1}, \lambda \in \mathbb{R}$, belongs to $A_{\{z_1, z_1^{-1}\}}$, whence $g_1 \in A_{\{z_1, z_1^{-1}\}}$ by definition. Thus, the function $h_1 := \tilde{g}_1 \circ \psi_1^{-1}$ belongs to $A_F$ and is continuous outside $z_1$, and $f_1 := f - h_1 \in \text{SAP}(F^1) \cap H^\infty$, where $F^1 := F \setminus \{z_1\}$. By using similar arguments, we can find a function $h_2 \in A_F$ continuous outside $z_2$ and such that $f_2 := f_1 - h_2 \in \text{SAP}(F^2) \cap H^\infty$, where $F^2 := F^1 \setminus \{z_2\}$, etc. After $n$ steps we obtain functions $h_1, \ldots, h_n \in A_F$ such that $h_k$ is continuous outside $z_k$, $1 \leq k \leq n$, and the function

$$h_{n+1} := f - \sum_{k=1}^{n} h_k$$

has no discontinuities on $\partial \mathbb{D}$; that is, $h_{n+1} \in A_0$. Therefore, $f \in A_F$.

Next, if $F$ consists of a single point, say $z_0$, then for any $f \in \text{SAP}(F) \cap H^\infty$ the above argument yields a function $h \in A_{\{z_0, z_1\}}$ with a fixed $z_1 \in \partial \mathbb{D}$ such that $f - h$ is continuous on $F$. Let $g \in A_0$ be a function equal to 1 on $F$ and to 0 at $z_1$. Then $f - gh \in A_0$. This completes the first part of the proof.

Now we show that $A_F \subset \text{SAP}(F) \cap H^\infty$. Again, assume first that $F$ contains at least two points. Let $e^{i\lambda f} \in A_F, \lambda \in \mathbb{R}$, where $\text{Re} f$ is the characteristic function of an arc, say $[x, y]$, with $x, y \in F$. Let $\psi : \partial \mathbb{D} \to \partial \mathbb{D}$ be the restriction to $\partial \mathbb{D}$ of a Möbius transformation sending 1 to $x$ and $-1$ to $y$. Then

$$(f \circ \psi \circ \phi_1^{-1})(z) = \frac{i}{\pi} \log z + C, \quad z \in \mathbb{H}_+,$$

for some constant $C$. Thus, we have

$$e^{i\lambda f \circ \psi \circ (\log \circ \psi_1)^{-1}}(z) = e^{\lambda C e^{-i\lambda z/\pi}}, \quad z \in \Sigma.$$ 

This means that $e^{i\lambda f \circ \psi} \in \text{SAP}(\{-1, 1\}) \cap H^\infty$. Then $e^{i\lambda f} \in \text{SAP}(F) \cap H^\infty$ by Corollary 1.6. Since $A_F$ is generated by $A_0$ and such functions $e^{i\lambda f}$, we arrive at the required implication.

If $F$ is a single point, then we must show that $ge^{i\lambda f} \in \text{SAP}(F) \cap H^\infty, \lambda \in \mathbb{R}$, where $\text{Re} f$ is the characteristic function of an arc with endpoint $F$, and $g \in A_0$ is such that $ge^{i\lambda f}$ has discontinuity at $F$ only. The result follows easily from the preceding part of the proof, because $e^{i\lambda f}$ is almost periodic on $\partial \mathbb{D} \setminus \{F, y\}$ for some $y$ and is continuous at $y$.

This completes the proof of the lemma. \hfill \square

As was mentioned above, the required statement of the theorem follows from Lemmas 1.7 and 1.8. \hfill \square

4.3. Proof of Example 1.10. Using the bilinear transformation $\phi_1 : \mathbb{D} \to \mathbb{H}_+$ (see (1.1)) that maps 1 to 0 in $\mathbb{R}$ and $-1$ to $\infty$, we can transform the problem to a similar one for functions on $\mathbb{H}_+$. Namely, let $\{x_k\}_{k \in \mathbb{N}} \subset \mathbb{R}_+$ be the sequence converging to 0 that is the image of the sequence $\{e^{it_k}\}_{k \in \mathbb{N}} \subset \partial \mathbb{D}$ in Example 1.10 under $\phi_1$. Let $H : \mathbb{R} \to \{0, 1\}$ be the Heaviside function (i.e., the characteristic function of $[0, \infty)$). Then the pullback by $\phi_1^{-1}$ of the function $u$ in Example 1.10 to the boundary $\mathbb{R}$ of $\mathbb{H}_+$ is the function

$$\tilde{u}(x) := \sum_{k=1}^{\infty} a_k H(x - x_k), \quad x \in \mathbb{R}.$$
We set \( \tilde{h} := \tilde{u} + i\tilde{v} \). Then \( \tilde{h} \) is the pullback by \( \phi_1^{-1} \) of a holomorphic function \( h \) on \( \mathbb{D} \) such that \( \text{Re} h|_{\partial \mathbb{D}} = u \). Assume, to the contrary, that \( e^{ih} \in A_S \). Since \( e^{iu} \in R_S \), this assumption implies that \( e^{iv} \in \text{SAP}(S) \), where \( v = \phi_1'(\tilde{v}|_{\mathbb{R}}) \). Then, by the definition of the topology on \( \text{M(SAP}(S)) \), see Subsection 3.3, the functions \( \cos(\tilde{v}(e^t)) \) and \( \sin(\tilde{v}(e^t)) \), \( t \in \mathbb{R} \), admit continuous extensions to \( b\mathbb{R} \); these extensions are determined as follows.

If \( \{\alpha_k\} \subset \mathbb{R} \) is a net converging in \( b\mathbb{R} \) to a point \( \eta \in b\mathbb{R} \), then the values at \( \eta \) of the extended functions are

\[
\lim_{\alpha} \cos(\tilde{v}(e^{s\alpha})) \quad \text{and} \quad \lim_{\alpha} \sin(\tilde{v}(e^{s\alpha})),
\]

respectively. In particular, this definition requires the existence of these limits.

Now, by (4.7), there are sequences of points \( \{x'_k\}_{k \in \mathbb{N}} \) and \( \{x''_k\}_{k \in \mathbb{N}} \) in \( \mathbb{R} \), such that \( x'_k \) and \( x''_k \) are sufficiently close to \( x_k \) and

\[
\lim_{k \to \infty} \frac{|x'_k|}{|x''_k|} = 1, \quad \cos(\tilde{v}(x'_k)) = 0, \quad \cos(\tilde{v}(x''_k)) = 1, \quad k \in \mathbb{N}.
\]

We set \( t'_k := \ln x'_k \) and \( t''_k := \ln x''_k \), \( k \in \mathbb{N} \). Without loss of generality, we assume that \( \{t'_k\} \) forms a net converging in the topology of \( b\mathbb{R} \) to a point \( \xi \in b\mathbb{R} \) (otherwise we replace \( \{t_k\} \) by a proper subset satisfying this property). Since \( \lim_{k \to \infty} |t'_k - t''_k| = 0 \) by definition, and almost periodic functions on \( \mathbb{R} \) are uniformly continuous, the family \( \{t''_k\} \) forms a net with the same indices as for the net formed by \( \{t'_k\} \) whose limit in \( b\mathbb{R} \) is \( \xi \). Hence, we have

\[
\lim_{k \to \infty} \cos(\tilde{v}(e^{t'_k})) = \lim_{k \to \infty} \cos(\tilde{v}(e^{t''_k})),
\]

a contradiction. Therefore, \( e^{ih} \not\in A_S \).

Now, let \( f \in A_0 \) be such that \( f(1) = 0 \). Then the function \( (fe^{ih})|_{\partial \mathbb{D}} \) is continuous at \( 1 \). Thus, \( (fe^{ih})|_{\partial \mathbb{D}} \) can be uniformly approximated by constant functions on open arcs containing \( 1 \). The same is true for each point \( e^{it_k} \). This implies immediately that \( fe^{ih} \in A_S \).

\[\text{§5. Proofs of Theorems 1.12 and 1.14}\]

5.1. Proof of Theorem 1.12 We recall that \( A_S \) is the uniform closure of the algebra generated by all possible \( A_F \) with finite \( F \subset S \). Therefore, the maximal ideal space \( \text{M}(A_S) \) of \( A_S \) is the inverse limit of the maximal ideal spaces \( \text{M}(A_F) \) of \( A_F \). In particular, if we prove that \( \mathbb{D} \) is dense in each \( \text{M}(A_F) \), then, by the definition of the inverse limit, this will imply that \( \mathbb{D} \) is dense in \( \text{M}(A_S) \), as required. Thus, it suffices to prove the theorem for \( A_F \) with \( F = \{z_1, \ldots, z_n\} \subset \partial \mathbb{D} \).

Theorem 5.1. \( \mathbb{D} \) is dense in \( \text{M}(A_F) \).

Proof. Let \( \mathcal{I}_k \subset A_F \) be the closed ideal consisting of all functions that are continuous and equal to \( 0 \) at \( z_k \). Let \( A_k \) denote the quotient Banach algebra \( A_F/\mathcal{I}_k \) equipped with the quotient norm. We recall that \( \text{M}_{z_k} \) is the maximal ideal space of the algebra \( A_{z_k} \), which is the uniform closure of the algebra of functions continuous on \( \mathbb{D} \) and almost periodic in circular neighborhoods of \( z_k \). Also, by Lemma 4.4 (b), there is a natural continuous projection \( p_{z_k} : \text{M}_{z_k} \to \mathbb{D} \), and \( p_{z_k}^{-1}(z_k) \) is homeomorphic to \( \text{M}(AP_{\mathbb{D}}(\Sigma)) \). Moreover, by Lemma 4.4 (c), each \( f \in A_F \) extends to a function continuous on \( \text{M}_{z_k} \) and holomorphic on \( p_{z_k}^{-1}(z_k) \). Hence, there is a continuous map \( H_k : \text{M}_{z_k} \to \text{M}(A_F) \) whose
image coincides with the closure of $\mathbb{D}$. Moreover, in accordance with the decomposition obtained in the proof of Lemma 1.8 see (4.6), $H_k$ maps $p_{z_k}^{-1}(z_k)$ homeomorphically onto its image.

**Lemma 5.2.** Let $\phi_k : A_F \to AP_0(\Sigma)$ be the composition of the homomorphism of extension of functions in $A_F$ to $\mathcal{M}_{z_k}$ and the homomorphism of restriction of functions on $\mathcal{M}_{z_k}$ to $p_{z_k}^{-1}(z_k)$. Then $\ker \phi_k = \mathcal{I}_k$ and $A_k$ is isomorphic to $AP_0(\Sigma)$.

**Proof.** Clearly, $\mathcal{I}_k \subset \ker \phi_k$. We check the reverse inclusion. Let $f \in \ker \phi_k$. The proof of Lemma 1.8 see (4.4), shows that there are continuous linear operators $T_k : AP_0(\Sigma) \to A(z_k) \subset A_F$ such that $\phi_k \circ T_k = \text{id}$. Moreover, $T_0 := I - \sum_{k=1}^{\infty} T_k \circ \phi_k$, where $I$ is the identity map, maps $A_F$ onto $A_0$. In particular, we have $T_k(\phi_k(f)) = 0$. Thus, $f = -T_0(f) + \sum_{g \in \mathbb{D}} T_k(\phi_k(f))$. Since $\phi_k(f) = 0$, this implies that $f$ is continuous and equal to 0 at $z_k$. Now from the formula $\phi_k \circ T_k = \text{id}$, it follows that $A_k$ is isomorphic to $AP_0(\Sigma)$. □

Let $i : A_0 \hookrightarrow A_F$ be the natural inclusion. Its dual determines a continuous surjective map $a_F : \mathcal{M}(A_F) \to \hat{\mathbb{D}}$. Taking the dual map to $\phi_k$, we see that each $\mathcal{M}(AP_0(\Sigma))$ is embedded in $\mathcal{M}(A_F)$, its image coincides with $H_k(p_{z_k}^{-1}(z_k))$, and $a_F$ maps $H_k(p_{z_k}^{-1}(z_k))$ to $z_k$.

Let $\xi \in \mathcal{M}(A_F)$, and let $m := \ker \xi \subset A_F$ be the corresponding maximal ideal. First, assume that there exists $k$ such that $\mathcal{I}_k \subset m$. Then $m_k = \phi_k(m)$ is a maximal ideal of $A_k$. Let $\xi_k \in \mathcal{M}(AP_0(\Sigma))$ denote the character corresponding to $m_k$. Then $\xi = \phi^*(\xi_k) \in H_k(p_{z_k}^{-1}(z_k))$. Now, by the definition of $H_k$, the point $\xi$ belongs to the closure of $\mathbb{D}$ in $\mathcal{M}(A_F)$. We continue with the following lemma.

**Lemma 5.3.** Assume that a maximal ideal $m$ of $A_F$ contains none of $\mathcal{I}_k$. Then $m$ does not contain $\bigcap_{1 \leq k \leq n} \mathcal{I}_k$.

**Proof.** Suppose, to the contrary, that $\bigcap_{1 \leq k \leq n} \mathcal{I}_k \subset m$. Let $x_k \in \mathcal{I}_k$, $1 \leq k \leq n$, be such that $x_k \notin m$. Since $\mathcal{I}_k$ are ideals, $x_1 \cdots x_n \in \bigcap_{1 \leq k \leq n} \mathcal{I}_k$. Thus, $x_1 \cdots x_n \in m$. Since $m$ is a prime ideal, there is some $k$ such that $x_k \in m$, a contradiction. □

This lemma shows that for the proof of the theorem it remains to consider the case where $m \notin \bigcap_{1 \leq k \leq n} \mathcal{I}_k$. Observe that $\bigcap_{1 \leq k \leq n} \mathcal{I}_k$ consists of all functions in $A_0$ that vanish on $F$. Thus, there is $f \in \bigcap_{1 \leq k \leq n} \mathcal{I}_k$ such that $f(\xi) \neq 0$. This implies that $a_F(\xi) \notin F$. For every $g \in A_F$, consider the function $g f$. By definition, $g f \in A_0$. Thus, we have $g(a_F(\xi)) f(a_F(\xi)) = (g f)(a_F(\xi)) = (g f)(\xi) = g(\xi) f(\xi) = g(\xi) f(a_F(\xi))$. Equivalently, $g(\xi) = g(a_F(\xi))$ for all $g \in A_F$.

This implies that $a_F^{-1}(a_F(\xi)) = \{\xi\}$. Therefore, $a_F : \mathcal{M}(A_F) \setminus a_F^{-1}(F) \to \overline{\mathbb{D}} \setminus F$ is a homeomorphism. In particular, $\xi$ belongs to the closure of $\mathbb{D}$.

The proof of Theorem 1.12 is complete. □

**5.2. Proof of Theorem 1.14.** Statements (1) and (3) of the theorem follow easily from similar statements for $a_F$ with a finite subset $F \subset S$, proved in Subsection 5.1, and the properties of the inverse limit. To prove (3), we start with the case of a finite subset $F \subset S$.

Since $A_0 \subset A_F$ and the modulus of each function in $A_0$ attains its maximum on $\partial \mathbb{D}$, we have $K_F \subset a_F^{-1}(\partial \mathbb{D})$. Theorem 1.8 shows that $A_F \hookrightarrow \text{SAP}(F)$. Also, the extensions of functions in $A_F$ to $\mathcal{M}(\text{SAP}(F))$ separate points there. Therefore, $\mathcal{M}(\text{SAP}(F))$ embeds in $\mathcal{M}(A_F)$. Identifying $\mathcal{M}(\text{SAP}(F))$ with its image under this embedding, we have
\(\mathcal{M}(\text{SAP}(F)) \subset a_F^{-1}(\partial D)\). Since \(a_F^{-1}(\partial D) \setminus a_F^{-1}(F) \to \partial D \setminus F\) is a homeomorphism and each \(z \in \partial D\) is a peak point for \(A_0\), the set \(K_F\) contains the closure of \(D \setminus F\), which, by definition, coincides with \(\mathcal{M}(\text{SAP}(F))\). Assume that there exists \(\xi \in K_F \setminus \mathcal{M}(\text{SAP}(F))\). Then \(a_F(\xi) := z^* \in F\). Next, identifying \(a_S^{-1}(z^*)\) with \(\mathcal{M}(\text{AP}_\Theta(\Sigma))\), from our assumption we deduce that \(\xi \in i_\eta(\Sigma_0)\) for some \(\eta \in b\mathbb{Z}\); see §2. Here \(\Sigma_0\) is the interior of \(\Sigma\). Then, since \(i_\eta(\Sigma_0)\) is dense in \(\mathcal{M}(\text{AP}_\Theta(\Sigma))\), each function \(f \in A_F\) with \(\max_D |f| = |f(\xi)|\) is constant on \(a_S^{-1}(z^*)\) by the maximum modulus principle. Thus, such an \(f\) attains the maximum of the modulus also on \(\mathcal{M}(\text{SAP}(F))\). This contradicts the minimality of \(K_F\).

Furthermore, \(\mathcal{M}(\text{SAP}(S))\) is the inverse limit of compact sets \(\mathcal{M}(\text{SAP}(F))\) for all finite \(F \subset S\). As before, we naturally identify \(\mathcal{M}(\text{SAP}(S))\) with a subset of \(\mathcal{M}(A_S)\). Then, since \(A_S\) is the uniform closure of the algebra generated by all possible \(A_F\) with finite \(F \subset S\), we have \(K_S \subseteq \mathcal{M}(\text{SAP}(S))\) by the definition of the inverse limit. But in fact the set \(K_S\) coincides with \(\mathcal{M}(\text{SAP}(S))\), because otherwise its projection to some of \(\mathcal{M}(A_F)\) is a boundary of \(A_F\) and a proper subset of \(\mathcal{M}(\text{SAP}(F))\), a contradiction.
