MAHLER MEASURES
OF ELLIPTIC MODULAR SURFACES

FRANÇOIS BRUNAULT AND MICHAEL NEURURER

ABSTRACT. We develop a new method for relating Mahler measures of three-variable polynomials that define elliptic modular surfaces to \(L\)-values of modular forms. Using an idea of Deninger’s, we express the Mahler measure as a Deligne period of the surface and then apply the first author’s extension of the Rogers–Zudilin method for Kuga–Sato varieties to arrive at an \(L\)-value.

1. Introduction

Let \(P \in \mathbb{C}(X_1, \ldots, X_n)\) be a nonzero Laurent polynomial. The (logarithmic) Mahler measure \(m(P)\) of \(P\) is defined as the average of \(\log |P|\) on the \(n\)-torus \(T^n = (S^1)^n\):

\[
m(P) = \frac{1}{(2\pi i)^n} \int_{T^n} \log |P(z_1, \ldots, z_n)| \frac{dz_1}{z_1} \wedge \cdots \wedge \frac{dz_n}{z_n}.
\]

If \(n = 2\) and \(P\) defines an elliptic curve \(E\), the work of Boyd [9] and Deninger [13] shows that under certain additional conditions on \(P\), the Mahler measure \(m(P)\) should be related to the \(L\)-value of \(E\) at \(s = 2\). Boyd conjectured many remarkable relations of the form

\[
m(P) = r \Lambda(E, 2),
\]

where \(r \in \mathbb{Q}^\times\) and \(\Lambda(E, s)\) denotes the completed \(L\)-function of \(E\). While Boyd’s conjectures remain open in general, a number of special cases have been established in recent years, see, e.g., [21], [31], [11].

In a series of papers [2,3] Bertin derived similar identities between the Mahler measure of a polynomial defining an elliptic K3 surface and the \(L\)-value of the associated newform of weight 3 at \(s = 3\). She studies families of K3 surfaces defined by families of polynomials \(P_k(X, Y, Z) = X + \frac{1}{k} + Y + \frac{1}{k} + Z + \frac{1}{k} - k\) and another family \(Q_k\). One crucial ingredient in her proof is that the derivatives of \(m(P_k)\) and \(m(Q_k)\) with respect to \(k\) are periods of the corresponding K3 surfaces and hence satisfy a Picard–Fuchs equation. Using this fact, she derives an expression of \(m(P_k)\) and \(m(Q_k)\) as an Eisenstein–Kronecker series that she can then relate to \(L\)-values for special values of \(k\) such as

\[
m(P_2) = 4 \Lambda(f_8, 3),
\]
where \( f_8 \) is the unique newform in \( S_3(\Gamma_1(8)) \). A similar approach was adopted in \([4, 23]\), where several more relations between Mahler measures and \( L \)-values were derived.

In this article we develop a new method for establishing identities such as \((1)\) for three-variable polynomials that define elliptic modular surfaces. It is based on a modification of Deninger’s approach in \([13]\) that, in favorable cases, allows us to express the Mahler measure of a polynomial as a Deligne period of the corresponding variety; in the three-variable case as the integral of a Deligne 2-form \( \eta \) over a 2-cycle \( D \). Our approach relies on explicitly identifying \( \eta \) in terms of Eisenstein symbols (see \( \S 5 \)) and \( D \) in terms of modular symbols (see \( \S 4 \)), and then on applying the results of \([12]\) to evaluate the integral. The strength of our method lies in the fact that once the cycle \( D \) is identified, most other steps can be performed algorithmically.

In the following theorem we collect our results. For a congruence subgroup \( \Gamma \) the surface \( E(\Gamma) \) is the universal elliptic curve over the (open) modular curve \( Y(\Gamma) \); see \( \S 4.2 \). Each equation is preceded by \( \Gamma \), signifying that the given Laurent polynomial defines a model for \( E(\Gamma) \). While the first of our results were found by Bertin \([2]\) with a different method, the rest, to our knowledge, are new.

**Theorem 1.1.** For \( N \in \{8, 12, 16\} \), let \( f_N \) denote the unique newform in \( S_3(\Gamma_1(N)) \) with rational Fourier coefficients. We have

\[
\begin{align*}
\Gamma_1(8) : m(X + \frac{1}{X} + Y + \frac{1}{Y} + Z + \frac{1}{Z} - 2) &= 4\Lambda(f_8, 0), \\
\Gamma_1(8) : m((X - 1)^2(Y - 1)^2 - \frac{(Z - 1)^4}{Z^2}XY) &= 8\Lambda(f_8, 0), \\
\Gamma_1(4) \cap \Gamma_0(8) : m(X + \frac{1}{X} + Y + \frac{1}{Y} - 4Z - 4) &= 7\zeta(3) \pi^2 + \log(2), \\
\Gamma_1(6) : m((X + Y + 1) \left(\frac{1}{X} + \frac{1}{Y} + 1\right) - Z) &= 7\zeta(3) \pi^2, \\
\Gamma_1(6) \cap \Gamma(2) : m((X + Y + 1) \left(\frac{1}{X} + \frac{1}{Y} + 1\right) - 2\left(Z + \frac{1}{Z}\right) - 5) &= \frac{3}{2} \Lambda(f_{12}, 0) + \frac{\log(2)}{2}, \\
\Gamma(4) : m((X + 1)^2(Y + 1)^2 - 2\frac{(Z + 1)^4}{Z^3 + Z}XY) &= 4\Lambda(f_{16}, 0).
\end{align*}
\]

Note that there are no cusp forms of weight 3 for the congruence subgroups \( \Gamma_1(4) \cap \Gamma_0(8) \) and \( \Gamma_1(6) \). Accordingly, the Mahler measures we obtain are combinations of \( L \)-values of Eisenstein series at \( s = 0 \).

In the following sections we will develop our method for general congruence subgroups, accompanying the general considerations with explicit calculations for Bertin’s polynomial \( P = P_2 \). In \([2]\) we recall part of Deninger’s work, expressing the Mahler measure of a three-variable polynomial as an integral of a Deligne 2-form \( \eta \) over an explicit 2-cycle \( D \) which we call the Deninger cycle. In \([3]\) we describe a way to parametrize \( V(P) \) by giving an explicit birational map from \( E(\Gamma_1(8)) \) to \( V(P) \). This construction was communicated to us by Odile Lecacheux, and we also use it for all of the other surfaces we treat. In \( \S \S 4 \) and \( 5 \) we describe explicit cycles and motivic cohomology classes on the modular surface \( E(\Gamma) \). The Shokurov cycles are closely connected to modular symbols, and ultimately we want to express the
Deninger cycle $D$ in terms of such cycles. The cohomology classes, cup products of Eisenstein symbols, are natural elements of $\mathrm{H}^{k+2}_M(E(\Gamma)^k, \mathbb{Q}(k+2))$ first constructed by Beilinson in the case $k = 0$ and extended by Deninger and Scholl and also Gealy for general $k$. In [41] we describe how to associate to a Milnor symbol on $E(\Gamma)$ an Eisenstein symbol, which we use to express the form $\eta$ in terms of Eisenstein symbols. In [42] we recall some basic facts about Deligne–Beilinson cohomology and the Beilinson regulator map.

Several of Boyd’s conjectures were solved by expressing Mahler measures as integrals of Eisenstein symbols over modular symbols using the Rogers–Zudilin method. In the two-variable case this reduces to calculating the regulator of two Siegel units in terms of $L$-values of weight 2 modular forms (see [14]). Brunault extended this calculation to deal with regulators of higher order Eisenstein symbols. In particular, this allows one to express the integral of an Eisenstein symbol over the Shokurov cycle $gX\{g_0, g_{\infty}\}$ for any $g \in \text{SL}_2(\mathbb{Z})$ in terms of $L$-values. Hence we try to decompose the Deninger cycle into a linear combination of cycles of the form $gX\{g_0, g_{\infty}\}$. While every Shokurov cycle is homologous to such a linear combination, we encounter several difficulties, coming from the fact that the Shokurov cycles are cycles on a compactification of $E(\Gamma)$, while the Eisenstein symbols do not extend to cohomology classes on the compactification. This means that an integral of an Eisenstein symbol over a Shokurov cycle is not necessarily absolutely convergent. Furthermore, even given absolute convergence, it is not always true that the integral of an Eisenstein symbol over a coboundary vanishes, so integrals over homologous cycles might not be equal. We carefully deal with these technical difficulties in [44].

In [48] we describe in detail how our method works for Bertin’s polynomial $P_2$. In the final section, [49], we give conditions on the three-variable polynomial $P$ under which we expect that our method gives a connection between $m(P)$ and an $L$-value. We describe how to construct polynomials satisfying our conditions and derive the new formulas listed in Theorem [11].

The search for models that satisfy our conditions was performed in Magma [7], and we give more details on the algorithm in [49]. Given a model satisfying the three conditions, all other steps described above can be performed algorithmically, and we implemented them in Sage [29]. In order to check our results and find other examples, we used MATLAB [20] to numerically approximate the Mahler measures.

2. The Deninger cycle

Let $P \in \mathbb{C}[X^{\pm 1}, Y^{\pm 1}, Z^{\pm 1}]$ be given by $P(X, Y, Z) = \sum_{i=0}^{i_0} a_i(X, Y)Z^i$, with $a_i(X, Y) \neq 0$, and define $P^+(X, Y) = a_{i_0}(X, Y)$. We denote by $V(P)$ the (reduced) zero locus of $P$ in $\mathbb{G}^3_m$. Then by Jensen’s formula

$$m(P) - m(P^+) = \frac{1}{2\pi i} \int_{(T^2 \times U) \cap V(P)} \log |Z| \frac{dX}{X} \wedge \frac{dY}{Y},$$

where $T^2 = \{(X, Y) : |X| = |Y| = 1\}$ and $U = \{Z : |Z| > 1\}$.

**Definition 2.1.** The Deninger 2-cycle $D_P$ is defined by

$$D_P = (T^2 \times U) \cap V(P).$$

Note that $D_P$ carries a natural orientation arising from the natural orientation on $T^2$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
We now focus on the polynomial \( P(X, Y, Z) = X + \frac{1}{X} + Y + \frac{1}{Y} + Z + \frac{1}{Z} - 2 \), for which we give a more explicit description of the Deninger cycle \( D_P \).

**Lemma 2.1.**

\[
D_P = \{ (e^{i\phi}, e^{i\psi}, Z(\phi, \psi)) : \cos \phi + \cos \psi < 0, \\
Z(\phi, \psi) = 1 - \cos \phi - \cos \psi + \sqrt{1 - \cos \phi - \cos \psi)^2 - 1} \}.
\]

**Proof.** Let \((X, Y, Z) \in D_P\). Since \((X, Y) \in T^2\), we have

\[
P(X, Y, Z) = 2 \Re(X) + 2 \Re(Y) + Z + \frac{1}{Z} - 2.
\]

The equation \( P(X, Y, Z) = 0 \) is equivalent to

\[
Z + \frac{1}{Z} = 2(1 - \Re(X) - \Re(Y)).
\]

In particular, \( Z + \frac{1}{Z} \in \mathbb{R} \), which implies \( Z \in \mathbb{R} \cup S^1 \). Since we assume that \( |Z| > 1 \), we must have \( Z \in (-\infty, -1) \cup (1, +\infty) \). Therefore \( |Z + \frac{1}{Z}| > 2 \), which implies that \( \Re(X) + \Re(Y) < 0 \) and \( Z > 1 \). \( \square \)

The region where \( \cos \phi + \cos \psi < 0 \) is (up to translations by \( 2\pi \)) equal to the interior of the square with the corners \((0, \pi), (\pi, 2\pi), (\pi, 0), (2\pi, \pi)\), and \( Z \) varies between 1 and \( 3 + 2\sqrt{2} \).

**Lemma 2.2.** The map \((X, Y, Z) \mapsto Z\) defines a fibration of \( D_P \setminus \{ (-1, -1, 3 + 2\sqrt{2}) \} \) above the interval \((1, 3 + 2\sqrt{2})\). The fibers are homeomorphic to \( S^1 \) and are given by the implicit equation

\[
\cos \phi + \cos \psi = 1 - \frac{1}{2} \left( Z + \frac{1}{Z} \right).
\]

Note that for \( Z_0 \in (1, 3 + 2\sqrt{2}) \) we have \( Z_0 + \frac{1}{Z_0} - 2 \in (0, 4) \), and the projective closure of the curve \( P(X, Y, Z_0) = 0 \) is an elliptic curve.

### 3. The elliptic modular surface \( E_{1}(8) \)

By the work of Bertin and Lecacheux [5, §7.1] the elliptic modular surface \( E_{1}(8) \) associated with the group \( \Gamma_{1}(8) \) is a desingularization of the surface

\[
P(X, Y, Z) = X + \frac{1}{X} + Y + \frac{1}{Y} + Z + \frac{1}{Z} - 2 = 0.
\]

The modular curve \( Y_{1}(8) \) has genus 0, and the structural morphism \( E_{1}(8) \to Y_{1}(8) \) is given by \((X, Y, Z) \mapsto Z\).

We now give an explicit parametrization of the surface \( V(P) \) in terms of elliptic functions following a method of Lecacheux [19]. The birational transformation

\[
U = -XY, \quad V = -Y(XY + 1)
\]

puts \( V(P) \) into the Weierstrass form

\[
V^2 + \left( Z + \frac{1}{Z} - 2 \right) UV = U(U - 1)^2.
\]

Let \( A : Y_{1}(8) \to E_{1}(8) \) be the canonical section of order 8 on the universal elliptic curve. It has the coordinates

\[
(U_A, V_A) = (Z, Z - 1),
\]
and its multiples are given by
\[(U_{2A}, V_{2A}) = (1, 0), \quad (U_{4A}, V_{4A}) = (0, 0).\]

Let \(M = (U, V)\) be a section of \(E_1(8)\). We compute explicitly
\[
U(M + 2A) = 1 - \frac{(Z + \frac{1}{2} - 2) V}{(U - 1)^2},
\]
\[
V(M + 2A) = -\frac{(Z + \frac{1}{2} - 2)^2 V}{(U - 1)^3} + \frac{Z + \frac{1}{2} - 2}{U - 1}.
\]

In particular,
\[
U(M + 2A) - U_{2A} = -\frac{(Z - 1)^2}{Z} V \quad \frac{Z}{(U - 1)^2}.
\]

It follows that
\[
X = -\frac{U(U - 1)}{V} = \frac{(Z - 1)^2}{Z} \frac{U - U_{4A}}{(U(M + 2A) - U_{2A})(U - U_{2A})},
\]
\[
Y = \frac{V}{U - 1} = -\frac{Z}{(Z - 1)^2} \frac{(U(M + 2A) - U_{2A})(U - U_{2A})}{(U(M + 2A) - U_{2A})}.
\]

Since the fiber of \(E_1(8)(\mathbb{C})\) above \(\tau \in \mathcal{H}\) is isomorphic to \(\mathbb{C}/(\mathbb{Z} + \tau \mathbb{Z})\), there exists a parametrization of the form
\[
U = u^2 \varphi_\tau(z) + r, \quad V = u^3 \left(\frac{\varphi_\tau'(z)}{2}\right) + u^2 s \varphi_\tau(z) + t,
\]
where \(\varphi_\tau\) is the Weierstrass \(\varphi\)-function, and \(r, s, t, u\) depend only on \(\tau\). In particular, for any points \(M_1, M_2, M_3, M_4\) in the fiber of \(E_1(8)(\mathbb{C})\) above \(\tau\), we have
\[
\frac{U(M_1) - U(M_2)}{U(M_3) - U(M_4)} = \frac{\varphi_\tau(z_1) - \varphi_\tau(z_2)}{\varphi_\tau(z_3) - \varphi_\tau(z_4)},
\]
where \(M_i\) corresponds to \(z_i \in \mathbb{C}/(\mathbb{Z} + \tau \mathbb{Z})\).

Since the section \(A\) corresponds to \(z = 1/8\), we finally obtain \(X, Y, Z\) in terms of \(\varphi\):
\[
X = \frac{(\varphi_\tau(1/8) - \varphi_\tau(1/4))^2(\varphi_\tau(z) - \varphi_\tau(1/2))}{(\varphi_\tau(1/8) - \varphi_\tau(1/2))(\varphi_\tau(z + 1/4) - \varphi_\tau(1/4))(\varphi_\tau(z) - \varphi_\tau(1/4))},
\]
\[
Y = -\frac{(\varphi_\tau(1/8) - \varphi_\tau(1/2))(\varphi_\tau(z + 1/4) - \varphi_\tau(1/4))}{(\varphi_\tau(1/8) - \varphi_\tau(1/4))^2(\varphi_\tau(1/4) - \varphi_\tau(1/2))},
\]
\[
Z = \frac{\varphi_\tau(1/8) - \varphi_\tau(1/2)}{\varphi_\tau(1/4) - \varphi_\tau(1/2)}.
\]

The elliptic involution on \(E_1(8)\) is given by \((X, Y, Z) \mapsto (Y, X, Z)\), and thus \(Y(\tau, z) = X(\tau, -z)\). Note also that \(Z(\tau)\) is nonvanishing on the upper half-plane, so \(Z\) is a modular unit on \(Y_1(8)\).

**Lemma 3.1.** The Lecacheux parametrization identifies \(E_1(8) \setminus \langle 2A \rangle\) with the open subset of \(V(P) \subset \mathbb{C}^3_m\) defined by the condition \(Z \notin \{\pm 1, 3, 2\sqrt{2}\}\). In particular, we may identify the Deninger cycle \(D_P \setminus \{-1, -1, 3, 2\sqrt{2}\}\) with a cycle on \(E_1(8)(\mathbb{C})\).
We then have an isomorphism $\mathbb{Z}/4\mathbb{Z}$.

Proof. The above construction gives a map $\phi : E_1(8) \setminus \langle 2A \rangle \to V(P) \subset \mathbb{G}_m^3$, which is easily seen to be injective. Since the cusps of $X_1(8)$ are given by the $\mathbb{Z}$-values $\{\infty, 0, \pm 1, 3 \pm 2\sqrt{2}\}$, the image of $\phi$ is contained in the open subset defined by $Z \notin \{\pm 1, 3 \pm 2\sqrt{2}\}$. Let us check surjectivity. For the excluded values of $Z$ we have $k = Z + 1/Z - 2 \in \{0, \pm 4\}$, and it suffices to check that for $k \neq 0, \pm 4$, the curve $\{X + 1/X + Y + 1/Y + k = 0\} \subset \mathbb{G}_m^2$ is an elliptic curve deprived of the subgroup generated by a point of order 4.

\[ \square \]

4. Shokurov cycles

In this section we fix an integer $N \geq 4$.

4.1. Modular curves. We recall here some basic facts on modular curves following [14, §1].

Let $Y_1(N)$ be the modular curve over $\mathbb{Q}$ classifying pairs $(E, P)$, where $E$ is an elliptic curve and $P$ is a section of exact order $N$ on $E$. We have an isomorphism $Y_1(N)(\mathbb{C}) \cong \Gamma_1(N) \backslash \mathcal{H}$.

Let $Y(N)$ be the modular curve over $\mathbb{Q}$ classifying triples $(E, e_1, e_2)$, where $E$ is an elliptic curve and $(e_1, e_2)$ is a $\mathbb{Z}/NZ$-basis of $E[N]$. The group $G = \text{GL}_2(\mathbb{Z}/NZ)$ acts from the left on $Y(N)$ by the rule $g : (E, e_1, e_2) = (E, e_1', e_2')$, with

\[
\begin{pmatrix}
    e_1' \\
    e_2'
\end{pmatrix} = g \begin{pmatrix}
    e_1 \\
    e_2
\end{pmatrix}.
\]

The canonical degeneracy map $\pi : Y(N) \to Y_1(N)$ given by $(E, e_1, e_2) \mapsto (E, e_2)$ induces an isomorphism $Y_1(N) \cong \Gamma \backslash Y(N)$ where

\[
\Gamma = \left\{ \begin{pmatrix} * & * \\ 0 & 1 \end{pmatrix} \right\} \subset \text{GL}_2(\mathbb{Z}/NZ).
\]

Following [14, 3.4], the complex points of $Y(N)$ can be described as

\[
Y(N)(\mathbb{C}) \cong \text{SL}_2(\mathbb{Z}) \backslash (\mathcal{H} \times G),
\]

and the action of $G$ is given by $g : (\tau, h) = (\tau, hg^T)$. The degeneracy map $\pi : Y(N)(\mathbb{C}) \to Y_1(N)(\mathbb{C})$ is determined by

\[
\pi \left( \tau, \begin{pmatrix} 0 & -1 \\ a & 0 \end{pmatrix} \right) = [\tau] \quad (\tau \in \mathcal{H}, a \in (\mathbb{Z}/NZ)^\times).
\]

4.2. Universal elliptic curves. Let us describe the complex points of the universal elliptic curve $E_1(N)$ over $Y_1(N)$. The semidirect product $\mathbb{Z}^2 \rtimes \text{SL}_2(\mathbb{Z})$ acts on $\mathcal{H} \times \mathbb{C}$ by the rules

\[
\begin{pmatrix} m & n \\ n & m \end{pmatrix} \cdot (\tau, z) = (\tau, z + m - n\tau),
\]

\[
\begin{pmatrix} a & b \\ c & d \end{pmatrix} \cdot (\tau, z) = \begin{pmatrix} a\tau + b & z \\ c\tau + d & c\tau + d \end{pmatrix}.
\]

We then have an isomorphism

\[
E_1(N)(\mathbb{C}) \cong (\mathbb{Z}^2 \rtimes \Gamma_1(N)) \backslash (\mathcal{H} \times \mathbb{C}),
\]

and the structural morphism $p_1 : E_1(N)(\mathbb{C}) \to Y_1(N)(\mathbb{C})$ is given by $p_1(\tau, z) = [\tau]$.

Let us now describe the complex points of the universal elliptic curve $E(N)$ over $Y(N)$ following [14, 3.4]. We have

\[
E(N)(\mathbb{C}) \cong (\mathbb{Z}^2 \rtimes \text{SL}_2(\mathbb{Z})) \backslash (\mathcal{H} \times \mathbb{C} \times G),
\]
where \( \text{SL}_2(\mathbb{Z}) \) acts by left multiplication on \( G \). The group \( G \) acts from the left on \( E(N) \) by the rule \( g \cdot (\tau, z, h) = (\tau, z, h g^T) \). The structural morphism \( p : E(N)(\mathbb{C}) \to Y(N)(\mathbb{C}) \) is the obvious one, and we have a commutative diagram

\[
\begin{array}{ccc}
E(N) & \xrightarrow{p} & Y(N) \\
\pi \downarrow & & \downarrow \pi \\
E_1(N) & \xrightarrow{\tilde{p}} & Y_1(N)
\end{array}
\]

where the map \( \tilde{p} \) is given by

\[
\tilde{p} \left( \tau, z, \begin{pmatrix} 0 & -1 \\ a & 0 \end{pmatrix} \right) = [\tau, z] \quad (\tau \in \mathcal{H}, z \in \mathbb{C}, a \in (\mathbb{Z}/\mathbb{N}\mathbb{Z})^\times).
\]

Note that the square (4) is cartesian: the universal elliptic curve \( E(N) \) can be identified with the base change of \( E_1(N) \) to \( Y(N) \).

4.3. Shokurov cycles. In this subsection, we define the Shokurov cycles on \( E_1(N)(\mathbb{C}) \) and \( E(N)(\mathbb{C}) \). These cycles were first studied by Shokurov [25] and are at the foundation of the theory of modular symbols.

Let \( \mathbb{Z}[X,Y]_1 \) be the space of homogeneous polynomials in \( X \) and \( Y \) of degree 1. Let \( \sigma \) denote the matrix \( \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \).

**Definition 4.1.** Let \( P = mX + nY \in \mathbb{Z}[X,Y]_1 \) and \( \alpha, \beta \in \mathcal{H} \cup \mathbb{P}^1(\mathbb{Q}) \). We define the 2-cycle \( P\{\alpha, \beta\}_1 \) on \( E_1(N)(\mathbb{C}) \) by

\[
P\{\alpha, \beta\}_1 = \{[\tau, t(m\tau + n)]: \tau \in \{\alpha, \beta\}, t \in [0, 1]\},
\]

where \( \{\alpha, \beta\} \) denotes the geodesic from \( \alpha \) to \( \beta \) in \( \mathcal{H} \).

We define the 2-cycle \( P\{\alpha, \beta\} \) on \( E(N)(\mathbb{C}) \) by

\[
P\{\alpha, \beta\} = \{[\tau, t(m\tau + n), \sigma]: \tau \in \{\alpha, \beta\}, t \in [0, 1]\}.
\]

The relation between Shokurov cycles on \( E(N) \) and \( E_1(N) \) is given by the following lemma.

**Lemma 4.1.** Let \( \tilde{\pi} : E(N)(\mathbb{C}) \to E_1(N)(\mathbb{C}) \) denote the canonical map. For every \( P \in \mathbb{Z}[X,Y]_1 \) and every \( \alpha, \beta \in \mathcal{H} \cup \mathbb{P}^1(\mathbb{Q}) \), we have

\[
\tilde{\pi}_*(P\{\alpha, \beta\}) = P\{\alpha, \beta\}_1.
\]

**Proof.** This follows from (6). \( \square \)

The group \( \text{SL}_2(\mathbb{Z}) \) acts from the left on \( \mathbb{Z}[X,Y]_1 \) by \( \begin{pmatrix} a & b \\ c & d \end{pmatrix} P(X,Y) = P(dx - by, -cX + aY) \) and on \( \mathbb{P}^1(\mathbb{Q}) \) by Möbius transformations.

**Lemma 4.2.** For all \( \gamma \in \text{SL}_2(\mathbb{Z}) \) with reduction \( \bar{\gamma} \in \text{SL}_2(\mathbb{Z}/\mathbb{N}\mathbb{Z}) \), and for all cycles \( P\{\alpha, \beta\} \) on \( E(N)(\mathbb{C}) \), we have

\[
\bar{\gamma}_*(P\{\alpha, \beta\}) = \gamma P\{\gamma\alpha, \gamma\beta\}.
\]

**Proof.** Write \( \gamma = \begin{pmatrix} a & b \\ c & d \end{pmatrix} \). By definition, we have

\[
\bar{\gamma}_*(P\{\alpha, \beta\}) = \{[\tau, tP(\tau, 1), \sigma\bar{\gamma}^T]: \tau \in \{\alpha, \beta\}, t \in [0, 1]\}.
\]

Since \( \sigma\bar{\gamma}^T = \gamma^{-1}\sigma \), we get

\[
\bar{\gamma}_*(P\{\alpha, \beta\}) = \left\{ \left[ \gamma\tau, \frac{tP(\tau, 1)}{ct + d}, \sigma \right]: \tau \in \{\alpha, \beta\}, t \in [0, 1] \right\}.
\]
On the other hand, we have
\[ γP[γα, γβ] = \{ [γτ, t \cdot (γP)(γτ, 1), σ] : τ ∈ \{α, β\}, t ∈ [0, 1] \}, \]
and a simple computation shows that \((γP)(γτ, 1) = P(τ, 1)/(cτ + d)\).

**Lemma 4.3.** For any closed 2-form \(η\) on \(E(N)(C)\) and any \(τ_1, τ_2 \in H\), we have
\[
\int_{(mX+nY)(τ_1, τ_2)} η = m \left( \int_{X(τ_1, τ_2)} η \right) + n \left( \int_{Y(τ_1, τ_2)} η \right) \quad (m, n \in Z).
\]

**Proof.** For \(P \in Z[X, Y]_1\) consider the natural fibration \(p_p : P\{τ_1, τ_2\} → \{τ_1, τ_2\}\). For a given \(τ\) on the geodesic \(\{τ_1, τ_2\}\), the fiber of \(p_{mX+nY}\) over \(τ\) is homologous to \(m \cdot [p_X^{-1}(τ)] + n \cdot [p_Y^{-1}(τ)]\). Integrating over the fibers, this implies that
\[
\int_{p_{mX+nY}} η = m \int_{p_X} η + n \int_{p_Y} η.
\]
The lemma follows. \(\square\)

5. Eisenstein symbols

The goal of this section is to express the Milnor symbol \(\{X, Y, Z\}\) in terms of Eisenstein symbols on the universal elliptic curve \(E_1(8)\).

5.1. Siegel units. In this subsection we express \(Z\) in terms of Siegel units.

Let \(N \geq 3\) be an integer. For any \((a, b) \in (Z/NZ)^2\), \((a, b) \neq (0, 0)\), the Siegel unit \(g_{a,b} : H → \mathbb{C}^\times\) is defined by the following infinite product (see [16, §1]):
\[
g_{a,b}(τ) = q^{h/2B_2(\tilde{a}/N)} \prod_{n \geq 0} (1 - q^{n + \tilde{a}/N} ζ_N^n) \prod_{n \geq 1} (1 - q^{n - \tilde{a}/N} ζ_N^{-n}),
\]
where \(q^a = e^{2πiα}, ζ_N = e^{2πi/N}, B_2(X) = X^2 - X + \frac{1}{6}\) is the second Bernoulli polynomial, and \(\tilde{a} \in Z\) is the unique representative of \(a\) satisfying \(0 ≤ \tilde{a} < N\). Note that \(g_{-a,-b} = g_{a,b}\) when \(a \neq 0\), and \(g_{0,0} = 1\).

Under the action of \(SL_2(Z)\) on \(H\), the Siegel units transform by \(γ^*g_{a,b} = ζ^jg_{(a,b)γ}\) for some root of unity \(ζ\) [16, 1.6, 1.7]. This root of unity is given by the following proposition.

**Proposition 5.1.** Let \(a, b \in Z/NZ\), \((a, b) \neq (0, 0)\), and let \(γ \in SL_2(Z)\).

1. If \(γ = \left( \begin{array}{cc} 1 & k \ \\ 0 & \pm 1 \end{array} \right)\) for \(k \in Z\), then
\[
γ^*g_{a,b}(τ) = g_{a,b}(τ \pm k) = e^{±πi k B_2(\tilde{a}/N)} g_{a,±k+a+b}(τ).
\]

2. Assume that \(γ = (\tilde{a} \ t \ f \ d)\), with \(d > 0\). Denote \((a', b') = (a, b)γ\). The root of unity \((γ^*g_{a,b})/g_{a',b'}\) is determined by
\[
\arg \left( \frac{γ^*g_{a,b}}{g_{a',b'}} \right) ≡ π \frac{c}{d} B_2 \left( \frac{\tilde{a}}{N} \right) + \frac{f}{d} B_2 \left( \frac{\tilde{b'}}{N} \right) + δ(\tilde{a}) P_1 \left( \frac{b}{N} \right) - δ(\tilde{b'}) P_1 \left( \frac{b'}{N} \right) - 2\sum_{k=1}^{d} \left( \frac{1}{d} (k - \frac{\tilde{a}}{N}) \right) P_1 \left( \frac{c}{d} (k - \frac{\tilde{b}}{N}) - \frac{b}{N} \right) \mod 2π,
\]
where \(P_1(x) = B_1(\{x\}) = \{x\} - \frac{1}{2} \) if \(x \notin Z\), and \(P_1(0) = 0\) otherwise.
The first statement follows from the infinite product expansion of \( g_{a,b} \). The second follows from an explicit calculation of the limit of \( \arg g_{a,b}(c/d + it) \) when \( t \to 0 \). It is carried out in detail in \( [26, \text{proof of Thm. 13, pp. 135–143}] \). Following Siegel’s calculation, we find

\[
\lim_{t \to 0} \frac{\arg g_{a,b}(c/d + it)}{\pi} = \frac{c}{d} B_2 \left( \frac{\tilde{a}}{N} \right) + \delta(\tilde{a}) P_1 \left( \frac{b}{N} \right) - 2 \sum_{k=1}^{d} P_1 \left( \frac{1}{d}(k - \tilde{a}) \right) P_1 \left( \frac{c}{d}(k - \tilde{a}) - \frac{b}{N} \right) \mod 2\pi.
\]

Since \( (\gamma^* g_{a,b}) / g_{a',b'} \) is constant,

\[
g_{a,b}(c/d + it) = g_{a,b}(\gamma \gamma^{-1}(c/d + it)) g_{a',b'}(\gamma^{-1}(c/d + it)) \equiv (\gamma^* g_{a,b}) g_{a',b'} \left( \frac{i}{d^2} - \frac{f}{d} \right),
\]

so

\[
\lim_{t \to 0} \arg g_{a,b}(c/d + it) = \arg (\gamma^* g_{a,b}) + \lim_{t \to 0} \arg g_{a',b'} \left( \frac{i}{d^2} - \frac{f}{d} \right) \mod 2\pi \equiv \arg (\gamma^* g_{a,b}) + \arg (1 - \delta(\tilde{a}') \zeta_N^b - \pi \frac{f}{d} B_2 \frac{\tilde{a}'}{N}) \mod 2\pi.
\]

The second term equals \( \delta(\tilde{a}') \pi P_1 (b'/N) \).

Using Proposition 5.1, we can evaluate any quotient of Siegel units at any cusp.

**Proposition 5.2.** Let \( F = \prod_{i=1}^{k} g_{a_i,b_i} \), with \( c_i \in \mathbb{Z} \), be a quotient of Siegel units. Let \( \gamma' = (\tilde{a}' \tilde{f}) \in \text{SL}_2(\mathbb{Z}) \), and set \((a_i',b_i') = (a_i,b_i)\gamma'\). The quantity \( \text{ord}_{c/d} F := \frac{1}{2} \sum_{i=1}^{k} c_i B_2(\tilde{a}_i'/N) \) does not depend on a choice of \( \gamma \). If \( \text{ord}_{c/d} F \) is positive, then \( F(c/d) = \lim_{t \to 0} F(c/d + it) = 0 \), and if \( \text{ord}_{c/d} F \) is negative, the absolute value of \( F(c/d + it) \) diverges to \( \infty \). If \( \text{ord}_{c/d} F = 0 \), then

\[
F(c/d) := \lim_{t \to 0} F(c/d + it) = \prod_{i=1}^{k} \left( \gamma^* g_{a_i,b_i} \right)^{c_i} (1 - \delta(\tilde{a}_i') \zeta_N^{b_i'})^{c_i}.
\]

**Proof.** Writing \( g_{a_i,b_i} = (\gamma^* g_{a_i,b_i}) / g_{a_i',b_i'} \cdot (g_{a_i',b_i'} \circ \gamma^{-1}) \) as in the proof of Proposition 5.1, we get

\[
\lim_{t \to 0} F(c/d + it) = \prod_{i=1}^{k} \left( \gamma^* g_{a_i,b_i} \right)^{c_i} \lim_{t \to 0} \prod_{i=1}^{k} g_{a_i',b_i'}^{c_i} \left( \frac{i}{d^2} - \frac{f}{d} \right).
\]

The last limit equals

\[
\lim_{t \to \infty} \prod_{i=1}^{k} g_{a_i',b_i'}^{c_i} \left( \frac{it - f}{d} \right) = \left( \prod_{i=1}^{k} (1 - \delta(\tilde{a}_i') \zeta_N^{b_i'})^{c_i} \right) \lim_{t \to \infty} e^{2\pi \left( -t - \left( \frac{i}{d} \right) \text{ord}_{c/d} F \right)}.
\]

The proposition follows.

\footnote{To compare Siegel’s notation with ours, set \( u = \tilde{a}/N, v = -\tilde{b}/N \). Then \( \phi(u, v, z) = -ie^{-\pi (u-1)^2} g_{a,b} \).}
We denote by $O(Y(N))^\times$ the group of modular units on the modular curve $Y(N)$. After tensoring with $\mathbb{Q}$, the Siegel units are modular units of level $\Gamma(N)$, so they can be viewed as elements of $O(Y(N))^\times \otimes \mathbb{Q}$. Inside this $\mathbb{Q}$-vector space the Siegel units satisfy the transformation law $\gamma^* g_{a,b} = g_{(a,b)\gamma}$ for any $\gamma \in \text{GL}_2(\mathbb{Z}/N\mathbb{Z})$.

Note that the Siegel units $g_{0,b}$ with $b \in \mathbb{Z}/N\mathbb{Z}$, $b \neq 0$ are invariants under the group $\{(0,1)\}$ and therefore descend to modular units on $Y_1(N)$.

**Proposition 5.3.** We have the following identity:

$$Z(\tau) = (3 + 2\sqrt{2}) \prod_{n \geq 1} \frac{(1 - q^n \zeta_8^3)^2 (1 - q^n \zeta_8^{-3})^2}{(1 - q^n \zeta_8)^2 (1 - q^n \zeta_8^{-1})^2} = -i \left( \frac{g_{0,3}}{g_{0,1}} \right)^2. \quad (7)$$

**Proof.** Note that

$$Z(\tau) = \frac{\psi(\tau)(1/8) - \psi(\tau)(1/2)}{\psi(\tau)(1/4) - \psi(\tau)(1/2)}$$

is a Weierstrass unit in the terminology of Kubert and Lang [17, Chap. 2, §6], and Weierstrass units can be expressed in terms of Siegel units [10, Prop. 2.2]. To get the explicit expression, we write $Z$ in terms of the Weierstrass $\sigma$-function, using the fact that for $z_1, z_2 \in \mathbb{C}$ we have [27, Corollary 5.6(a)]

$$\sigma_\tau(z_1) - \sigma_\tau(z_2) = -\frac{\sigma_\tau(z_1 + z_2)\sigma_\tau(z_1 - z_2)}{\sigma_\tau(z_1)^2\sigma_\tau(z_2)^2}. $$

We get

$$Z(\tau) = \frac{\sigma(1/4)\sigma(3/8)\sigma(5/8)}{\sigma(3/4)\sigma(1/8)^2}. $$

We then use the product expansion for $\sigma_\tau(z)$ [27, Theorem 6.4] and the identity $3 + 2\sqrt{2} = -i(1 - \zeta_8^3/2(1 - \zeta_8)^2$ to confirm (7).}$\square$

5.2. **The Eisenstein symbol.** Let $X(N)$ be the compactification of $Y(N)$, and let $X(N)^\infty$ be the scheme of cusps of $X(N)$. We have a bijection

$$\left\{ \begin{pmatrix} \pm & \ast \\ 0 & 1 \end{pmatrix} \right\} \backslash \text{GL}_2(\mathbb{Z}/N\mathbb{Z}) \xrightarrow{\cong} X(N)^\infty \quad [g] \mapsto g^T \cdot \infty. \quad (7)$$

The vector space

$$V_N^\pm = \left\{ f : \text{GL}_2(\mathbb{Z}/N\mathbb{Z}) \rightarrow \mathbb{Q} : f \left( \begin{pmatrix} \ast & \ast \\ 0 & 1 \end{pmatrix} \right) = f(g) = \pm f(-g), g \in \text{GL}_2(\mathbb{Z}/N\mathbb{Z}) \right\}$$

is noncanonically isomorphic to the $\mathbb{Q}$-vector space with basis $X(N)^\infty$.

Let $k \geq 0$ be an integer, and let $E(N)^k$ be the $k$-fold fiber product of $E(N)$ over $Y(N)$. We denote motivic cohomology by $H_\mathcal{M}$. Beilinson [1] constructed a residue map

$$\text{Res}^k_\mathcal{M} : H^{k+1}_\mathcal{M}(E(N)^k, \mathbb{Q}(k+1)) \rightarrow V_N^{(-1)^k}$$

generalizing the divisor map $H^1_\mathcal{M}(Y(N), \mathbb{Q}(1)) \rightarrow V_N^+$ in the case $k = 0$. In the case $k \geq 1$ Beilinson also constructed a canonical right inverse of $\text{Res}^k_\mathcal{M}$, the *Eisenstein map*

$$E^k_\mathcal{M} : V_N^{(-1)^k} \rightarrow H^{k+1}_\mathcal{M}(E(N)^k, \mathbb{Q}(k+1)).$$
Definition 5.1. For any integer \( k \geq 0 \), the horospherical map
\[
\lambda^k : \mathbb{Q}((\mathbb{Z}/N\mathbb{Z})^2) \to V_N^{(-1)^k}
\]
is defined by
\[
\lambda^k(\phi)(g) = \sum_{x_1, x_2 \in \mathbb{Z}/N\mathbb{Z}} \phi\left(g^{-1}\left(\frac{x_1}{x_2}\right)\right) B_{k+2}\left(\left\{\frac{x_2}{N}\right\}\right) \quad (g \in \text{GL}_2(\mathbb{Z}/N\mathbb{Z})),
\]
where \( B_{k+2} \) is the \((k+2)\)th Bernoulli polynomial, and \( \{t\} = t - \lfloor t \rfloor \) is the fractional part of \( t \).

Definition 5.2. For any integer \( k \geq 1 \) and any \( u \in (\mathbb{Z}/N\mathbb{Z})^2 \), the Eisenstein symbol
\[
\text{Eis}^k(u) \in H_{k+1}^0(E(N)^k, \mathbb{Q}(k+1))
\]
is defined by \( \text{Eis}^k(u) = E^k_M \circ \lambda^k(\phi_u) \), where \( \phi_u = [u] \) is the characteristic function of \( \{u\} \).

Note that \( \text{Eis}^k(-u) = (-1)^k \text{Eis}^k(u) \) for any \( u \in (\mathbb{Z}/N\mathbb{Z})^2 \).

In the case \( k = 0 \) the image of the divisor map \( \text{Res}_{E_M}^0 \) is the space \((V_N^+)^0\) of degree 0 divisors on \( X(N)_{\infty} \) by the Manin–Drinfeld theorem. It can be shown that the Siegel units provide a canonical right inverse \( E^0_M : (V_N^+)^0 \to H^1(Y(N), \mathbb{Q}(1)) \) of \( \text{Res}_{E_M}^0 \). More precisely, the horospherical map \( \lambda^0 \) induces a map \( \mathbb{Q}((\mathbb{Z}/N\mathbb{Z})^2 \setminus \{0\}) \to (V_N^+)^0 \), and we have
\[
E^0_M \circ \lambda^0(\phi_u) = g_u \otimes \frac{2}{N} \quad (u \in (\mathbb{Z}/N\mathbb{Z})^2, u \neq (0, 0)).
\]
In analogy with Definition 5.2 we put \( \text{Eis}^0(u) = g_u \otimes (2/N) \) for any \( u \in (\mathbb{Z}/N\mathbb{Z})^2 \), \( u \neq (0, 0) \). Proposition 5.3 can thus be rewritten as follows.

Proposition 5.4. Let \( \pi : Y(8) \to Y_1(8) \) be the canonical projection map. Then
\[
\pi^*(Z) = 8(8\text{Eis}^0(0, 3) \setminus \text{Eis}^0(0, 1))
\]

5.3. Definition of the Eisenstein symbol in the case \( k = 1 \). Let us now recall the construction of the Eisenstein map in the case \( k = 1 \) following Deninger and Scholl [15]. The group \((\mathbb{Z}/N\mathbb{Z})^2 \equiv E(N)[N] \) acts by translation on \( E(N) \), and the group \( \{\pm 1\} \) acts on \( E(N) \) by means of the elliptic involution \( \iota : E(N) \to E(N) \). We thus get an action of \( H := (\mathbb{Z}/N\mathbb{Z})^2 \times \{\pm 1\} \) on \( E(N) \). Let \( \varepsilon : H \to \{\pm 1\} \) be the canonical projection.

Definition 5.3. For any \( \mathbb{Q}[H] \)-module \( M \) we denote by \( M^\varepsilon \) the \( \varepsilon \)-eigenspace of \( M \), and we denote by \( \Pi_\varepsilon : M \to M^\varepsilon \) the projector defined by
\[
\Pi_\varepsilon(m) = \frac{1}{|H|} \sum_{h \in H} \varepsilon(h) h \cdot m \quad (m \in M).
\]
Let \( U_N = E(N) - E(N)[N] \) be the complement of the \( N \)-torsion subgroup of \( E(N) \). It is stable by \( H \). The following theorem is due to Beilinson [1] Thm. 3.1.1.

Theorem 5.5.

1. The group \((\mathbb{Z}/N\mathbb{Z})^2 \) acts trivially on \( H^2_M(E(N), \mathbb{Q}(2)) \). In particular,
\[
H^2_M(E(N), \mathbb{Q}(2))^\varepsilon = H^2_M(E(N), \mathbb{Q}(2))^\sim,
\]
where \( (\cdot)^\sim \) denotes the subspace of anti-invariants under the elliptic involution.
Proof. Lemma 5.6. The map
\[ H^2_M(E(N), \mathbb{Q}(2)) \cong H^2_M(U_N, \mathbb{Q}(2)). \]

Consider now the map given by the cup-product
\[ \alpha : \mathcal{O}(U_N)^\times \otimes \mathcal{O}(U_N)^\times \to H^2_M(U_N, \mathbb{Q}(2)), \]
\[ g_0 \otimes g_1 \mapsto \{ t^*g_0, g_1 \}. \]

By Lemma 4.8 we have an exact sequence
\[ 0 \to \mathcal{O}(Y(N))^\times \otimes \mathbb{Q} \to \mathcal{O}(U_N)^\times \otimes \mathbb{Q} \xrightarrow{\text{div}} \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0 \to 0 \]
where div is the divisor map, and \( \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0 \) is the space of degree 0 divisors on \( (\mathbb{Z}/N\mathbb{Z})^2 \). Let \( \mu \) denote the product in the group algebra \( \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2] \). We have a diagram
\[ \mathcal{O}(U_N)^\times \otimes \mathcal{O}(U_N)^\times \otimes \mathbb{Q} \xrightarrow{\alpha} H^2_M(U_N, \mathbb{Q}(2)) \]
\[ \xrightarrow{\text{div} \otimes \text{div}} \]
\[ \bigotimes^2 \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0 \xrightarrow{\mu} \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0. \]

Lemma 5.6. The map \( \Pi \circ \alpha \) factors through the surjective map \( \text{div} \otimes \text{div} \).

Proof. It suffices to show that for any modular unit \( u \in \mathcal{O}(Y(N))^\times \) and any \( g \in \mathcal{O}(U_N)^\times \), we have \( \Pi_\epsilon(\{ u, g \}) = 0 \). Let us first average \( \{ u, g \} \) over the translations. We get
\[ \frac{1}{N^2} \sum_{a \in (\mathbb{Z}/N\mathbb{Z})^2} t^*_a \{ u, g \} = \frac{1}{N^2} \sum_{a \in (\mathbb{Z}/N\mathbb{Z})^2} \{ u, g \} = \frac{1}{N^2} \{ u, h \}, \]
with \( h = \prod_{a \in (\mathbb{Z}/N\mathbb{Z})^2} t^*_a g \). The function \( h \) has a trivial divisor, so it must come from the base. Now averaging over the group \( \{ \pm 1 \} \), we get \( \{ u, h \} - t^* \{ u, h \} = \{ u, h \} - \{ u, h \} = 0. \)

For any \( a \in (\mathbb{Z}/N\mathbb{Z})^2 \) let \( t_a : U_N \to U_N \) be the corresponding translation. We endow \( \mathcal{O}(U_N)^\times \otimes \mathcal{O}(U_N)^\times \) with the action of \( \text{H} \) defined by \( a \cdot (g_0 \otimes g_1) = (t^*_a g_0) \otimes (t^*_a g_1) \) for any \( a \in (\mathbb{Z}/N\mathbb{Z})^2 \), and \( -1 \cdot (g_0 \otimes g_1) = -(g_1 \otimes g_0) \). We also endow \( \bigotimes^2 \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0 \) with the action of \( \text{H} \) defined by \( a \cdot (d_0 \otimes d_1) = ([a]d_0) \otimes ([a]d_1) \) and \( -1 \cdot (d_0 \otimes d_1) = -(d_1 \otimes d_0) \). Finally, we endow \( \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0 \) with the trivial action of \( (\mathbb{Z}/N\mathbb{Z})^2 \) and the action of \( -1 \) given by \( -\text{id} \). In this way diagram \( \mathfrak{S} \) becomes \( \text{H} \) equivariant.

Lemma 5.7. The map \( \mu \) induces an isomorphism
\[ \left( \bigotimes^2 \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0 \right)^\varepsilon \cong \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0. \]

Proof. Let \( I = \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2]_0 \) denote the augmentation ideal of \( \mathbb{Q}[(\mathbb{Z}/N\mathbb{Z})^2] \). Note that with our definition \( I^\prime = I \), so we have a map \( \mu : (I \otimes I)^\varepsilon \to I \). We shall now construct an inverse of \( \mu \). Consider the divisor \( d_0 = N^2[0] - \sum_{u \in (\mathbb{Z}/N\mathbb{Z})^2} [u] \in I, \)
and define \( \theta : I \to (I \otimes I)^\varepsilon \) by \( \theta(d) = \Pi_\varepsilon(d \otimes d_0) \). A simple computation shows that \( \mu \circ \theta(d) = dd_0 = N^2 d. \)
Now let \( x = \sum_i d_i \otimes d_i^\prime \in (I \otimes I)^\varepsilon. \) We have
\[ \theta \circ \mu(x) = \sum_i \theta(d_i d_i^\prime) = \sum_i \Pi_\varepsilon((d_i d_i^\prime) \otimes d_0). \]
We claim that for any divisors \( d, d', d'' \) on \((\mathbb{Z}/N\mathbb{Z})^2\), we have
\[
\Pi_\varepsilon((dd'') \otimes d') = \Pi_\varepsilon(d \otimes (d'd'')),
\]
where we have extended the action of \( H \) to \( \mathbf{Q}((\mathbb{Z}/N\mathbb{Z})^2) \) in the natural way.
Indeed, formula (9) is trilinear with respect to \( d, d', d'' \), and it suffices to check it in the case \( d = [u], d' = [u'], \) and \( d'' = [u''] \), where it is obvious. It follows that
\[
\theta \circ \mu(x) = \sum_i \Pi_\varepsilon(d_i \otimes (d_i'd_i)) = N^2 \sum_i \Pi_\varepsilon(d_i \otimes d_i') = N^2 x.
\]
This shows that \((1/N^2)\theta\) is an inverse of \( \mu \).

By considering the \( \varepsilon \)-eigenspaces in the diagram (8) and using Lemmas 5.6 and 5.7, we get a unique map \( \mathcal{E}_M^1 : \mathbf{Q}((\mathbb{Z}/N\mathbb{Z})^2)^0 \to H^2_M(E(N), \mathbf{Q}(2))^- \) making the following diagram commute:
\[
\begin{array}{ccc}
\mathcal{O}(U_N)^\times \otimes \mathcal{O}(U_N)^\times \otimes \mathbf{Q} & \xrightarrow{\Pi_{\varepsilon, \text{op}}} & H^2_M(E(N), \mathbf{Q}(2))^- \\
\downarrow \text{div} \otimes \text{div} & & \\
\mathbf{Q}((\mathbb{Z}/N\mathbb{Z})^2)^0 & \xrightarrow{\frac{1}{N^2} \mu} & \mathbf{Q}((\mathbb{Z}/N\mathbb{Z})^2)^0.
\end{array}
\]

Note that we choose the bottom map to be \((1/N^2) \cdot \mu\) so that \( \mathcal{E}_M^1 \) coincides with the map \( \mathcal{E}_M^1 \) from [24]. To pass from \( \mathcal{E}_M^1 \) to the Eisenstein map \( \mathcal{E}_M^1 \), we use the horospherical map \( \lambda^1 \).

**Theorem 5.8** ([1],[24]).

1. The horospherical map \( \lambda^1 : \mathbf{Q}((\mathbb{Z}/N\mathbb{Z})^2)^0 \to V_N^- \) is surjective.
2. The map \( \mathcal{E}_M^1 \) factors through \( \lambda^1 \).
3. We have
\[
\text{Res}_M \circ \mathcal{E}_M^1 = \pm N^3 \frac{1}{3} \lambda^1.
\]

**Remark.** Part (1) is proved in [24, 7.5], and part (2) follows from [24, Theorem 7.4]. Note that there is a typo in [24, 2.6]: the formula at the top of p. 310 should read \( B_k(\zeta) := N^{-k-1} B_{k,N}(\zeta) \). Consequently, the constant in [24, Proposition 3.2] should be \( N/3 \) instead of \( 1/(3N) \), the constant in [24, Corollary 3.3] should be \( N^3/3 \) instead of \( N/3 \), and the constant \( C_{P,N}^n \) at the end of [24, §4] should be \( C_{P,N}^n = \pm N^{2n+1} (n+1)/(n+2)! \).

By Theorem 5.8(2), there is a commutative diagram
\[
\begin{array}{ccc}
\mathbf{Q}((\mathbb{Z}/N\mathbb{Z})^2)^0 & \xrightarrow{\mathcal{E}_M^1} & H^2_M(E(N), \mathbf{Q}(2))^- \\
\downarrow \lambda^1 & & \\
V_N^- & \xrightarrow{\mathcal{E}_M^1} & \\
& \text{(since the map is a right inverse of Res}_M^n \text{)}
\end{array}
\]
and by Theorem 5.8(3), the map \( E_M^1 := \pm (3/N^3) \cdot \mathcal{E}_M^1 \) is a right inverse of \( \text{Res}_M^n \).

Using Definition 5.2, we get the following expression of \( \mathcal{E}_M^1 \) in terms of the Eisenstein symbol.

**Corollary 5.9.** We have
\[
\mathcal{E}_M^1([u] - [0]) = \pm N^3 \frac{1}{3} \cdot \text{Eis}^1(u) \quad (u \in (\mathbb{Z}/N\mathbb{Z})^2).
\]
5.4. Expressing \( \{X, Y\} \) in terms of Eisenstein symbols.

**Lemma 5.10.** The Milnor symbol \( \{X, Y\} \) defines an element of \( H^2_{BM}(E_1(8), \mathbb{Q}(2))^- \).

**Proof.** Let \( t_{2A} \) denote the translation by \( 2A \) on \( E_1(8) \). By \([5, \text{proof of Corollary } 7.1]\) we have \( t_{2A}^*(X) = Y \) and \( t_{2A}^*(Y) = 1/X \), so \( t_{2A} \{X, Y\} = \{Y, 1/X\} = \{X, Y\} \). We check that the tame symbols of \( \{X, Y\} \) at the sections 0 and \( A \) are equal to 1. It follows that \( \{X, Y\} \) extends to an element of \( H^2_{BM}(E_1(8), \mathbb{Q}(2))^- \). Since \( \nu^* \{X, Y\} = \{Y, X\} = -\{X, Y\} \), we have \( \{X, Y\} \in H^2_{BM}(E_1(8), \mathbb{Q}(2))^- \). \( \square \)

We denote by \( \tilde{\pi} \) the canonical projection map \( E(8) \to E_1(8) \).

**Lemma 5.11.** We have
\[
\text{div}(\tilde{\pi}^*X) = -(0, 0) - (0, 2) + (0, 4) + (0, 6), \\
\text{div}(\tilde{\pi}^*Y) = -(0, 0) + (0, 2) + (0, 4) - (0, 6).
\]

**Proof.** By \([5, \S 7.4]\) the horizontal divisors of \( X \) and \( Y \) on \( E_1(8) \) are given by
\[
\text{div}(X) = -(0) - (2A) + (4A) + (6A), \\
\text{div}(Y) = -(0) + (2A) + (4A) - (6A).
\]

Note that the universal elliptic curve \( E(8) \) over \( Y(8) \) is canonically isomorphic to the base change \( E_1(8) \times_{Y(8)} Y(8) \). The base change of the section \( kA : Y_1(8) \to E_1(8) \) is the section \( (0, k) : Y(8) \to E(8) \), and the pullback of the divisor \( |kA| \) by \( \tilde{\pi} \) is simply the divisor \( [(0, k)] \). The lemma follows. \( \square \)

**Proposition 5.12.** We have \( \tilde{\pi}^* \{X, Y\} = \pm(64/3) \cdot \text{Eis}^1(0, 2) \).

**Proof.** By Theorem \( 5.5(1) \) and Lemma \( 5.10 \) the element \( \tilde{\pi}^* \{X, Y\} \) lies in the \( \varepsilon \)-eigenspace. Thus
\[
\tilde{\pi}^* \{X, Y\} = \Pi_\varepsilon(\tilde{\pi}^* \{X, Y\}) = \Pi_\varepsilon(\tilde{\pi}^* \{X, Y\} \otimes \tilde{\pi}^* \{\tilde{\pi}^* \{X, Y\}\}) = \Pi_\varepsilon(\tilde{\pi}^* \{\tilde{\pi}^* \{X, Y\}\} \otimes \tilde{\pi}^* \{\tilde{\pi}^* \{X, Y\}\})).
\]

The divisor of \( \tilde{\pi}^*Y \) is given by Lemma \( 5.11 \) and an explicit computation shows that
\[
\mu(\text{div}(\tilde{\pi}^*Y) \otimes \text{div}(\tilde{\pi}^*X)) = 4(0, 2) - 4(0, 0).
\]

Using diagram \( 10 \), we see that \( \tilde{\pi}^* \{X, Y\} = (1/64) \cdot \text{Eis}^1(4(0, 2) + 4(0, 6)) \). Using Corollary \( 5.9 \) we get \( \tilde{\pi}^* \{X, Y\} = \pm(32/3) \cdot (\text{Eis}^1(0, 2) - \text{Eis}^1(0, 6)) \). Since \( \text{Eis}^1(0, 6) = -\text{Eis}^1(0, 2) \), the proposition follows. \( \square \)

6. Deligne–Beilinson cohomology

In this section we briefly recall some facts on Deligne–Beilinson cohomology following Deninger \([13, \S 1]\). This provides a convenient setting for the various differential forms that appear in the next sections.

Let \( X \) be a smooth variety over \( \mathbb{C} \). For any \( i \geq 1 \) the Deligne–Beilinson cohomology group \( H^i_D(X, \mathbb{R}(i)) \) is defined by
\[
H^i_D(X, \mathbb{R}(i)) = \{ \phi \in A^{-1}(X, \mathbb{R}(i-1))|d\phi = \pi_{i-1}(\omega), \omega \in F^i(X)\}/dA^{i-2}(X, \mathbb{R}(i-1)),
\]
where \( A^i(X, \mathbb{R}(j)) \) are the smooth \( i \)-forms on \( X \) with values in \( \mathbb{R}(j) = (2\pi i)^j \mathbb{R} \), \( F^i(X) \) is the space of holomorphic \( i \)-forms on \( X \) with at most logarithmic singularities at infinity, and \( \pi_{i}(\alpha) = \frac{1}{i}(\alpha + (-1)^{i}\overline{\alpha}) \).

Note that the map \( \phi \mapsto \omega \) induces a well-defined linear map \( H^i_D(X, \mathbb{R}(i)) \to F^i(X) \).
As an example, for any invertible function $f$ in $O(X)$, the function log$|f|$ defines an element of $H^1_D(X,\mathbb{R}(1))$, and the associated holomorphic 1-form is dlog$|f|$.

There is a cup product on the Deligne–Beilinson cohomology groups

$$\cup : H^*_D(X,\mathbb{R}(i)) \times H^*_D(X,\mathbb{R}(j)) \to H^{i+j}_D(X,\mathbb{R}(i+j))$$

that is defined as follows. For $\alpha = i, j$ consider a class $[\phi_\alpha] \in H^*_D(X,\mathbb{R}(\alpha))$ represented by $\phi_\alpha \in A^{\alpha-1}(X,\mathbb{R}(\alpha-1))$ with $d(\phi_\alpha) = \pi_{\alpha-1}(\omega_\alpha)$ for $\omega_\alpha \in F^\alpha(X)$. Then the cup product

$$\phi_i \cup \phi_j = \phi_i \wedge \pi_j \omega_j + (-1)^i \pi_i \omega_i \wedge \phi_j$$

is in $A^{i+j-1}(X,\mathbb{R}(i+j-1))$ and satisfies

$$d(\phi_i \cup \phi_j) = \pi_{i+j-1}(\omega_i \wedge \omega_j).$$

The cup product of the classes $[\phi_i]$ and $[\phi_j]$ is given by

$$[\phi_i] \cup [\phi_j] = [\phi_i \cup \phi_j] \in H^{i+j}_D(X,\mathbb{R}(i+j)).$$

Let us now turn to the Beilinson regulator. Beilinson defined a $\mathbb{Q}$-linear map

$$\text{reg} : H^*_M(X,\mathbb{Q}(i)) \to H^*_D(X,\mathbb{R}(i)),$$

where $H^*_M(\cdot,\mathbb{Q}(i))$ denotes motivic cohomology. In the simplest case $i = 1$ we have $H^*_M(X,\mathbb{Q}(1)) \cong O(X)^\times \otimes \mathbb{Q}$, and the image of an invertible function $f \in O(X)^\times$ under the Beilinson regulator is simply the class of log$|f|$. Since the Beilinson regulator map is compatible with taking cup products, this determines the regulator of an arbitrary Milnor symbol $\{f_1, \ldots, f_n\} = f_1 \cup \cdots \cup f_n$ in $H^*_M(X,\mathbb{Q}(i))$.

### 7. Integrating Eisenstein Symbols over Shokurov Cycles

In this section we study integrals of Eisenstein symbols over Shokurov cycles. Since Eisenstein symbols have logarithmic singularities at the cusps, the integral over a Shokurov cycle does not always converge. One way to circumvent this problem is to regularize the integrals as in [12]. Here we give a criterion for when the integrals are absolutely convergent. This criterion will always be satisfied in our applications.

We first discuss realizations of Eisenstein symbols. Consider the Eisenstein symbol $\text{Eis}^n(u)$, where $n \geq 0$ and $u \in (\mathbb{Z}/N\mathbb{Z})^2$. In the case $n \geq 1$ Deninger defined in [14] §3 a canonical representative $\text{Eis}^n_D(u)$ of the Beilinson regulator of $\text{Eis}^n(u)$. It is a $\mathbb{R}(n)$-valued $n$-form on $E(N)^n(\mathbb{C})$ satisfying $d\text{Eis}^n_D(u) = \pi_n(\text{Eis}^n_{\text{hol}}(u))$ where $\text{Eis}^n_{\text{hol}}(u)$ is a holomorphic Eisenstein series of weight $n+2$ for the group $\Gamma(N)$. Note that $\text{Eis}^n_D(u)$ is a real analytic Eisenstein series [12] Prop. 5.4.

We extend the definition of $\text{Eis}^n_D(u)$ and $\text{Eis}^n_{\text{hol}}(u)$ to the case $n = 0$ by setting $\text{Eis}^0_D(u) = (2/N) \log|g_u|$ and $\text{Eis}^0_{\text{hol}}(u) = (2/N) \log|g_u|$ for every $u \neq (0,0)$. We can check that these definitions are consistent with [12] by applying the logarithm to the $q$-product expression for Siegel units. In particular, this argument shows that the Fourier expansions of $\text{Eis}^0_D(u)$ and $\text{Eis}^0_{\text{hol}}(u)$ are indeed given by the formulas in [12] §8. (Note that in the case $n = 0$, the series appearing in [12] Prop. 5.4 does not converge absolutely, and making sense of it requires Hecke summation.)

We now give the transformation property of Eisenstein symbols with respect to the group $\text{GL}_2(\mathbb{Z}/N\mathbb{Z})$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Lemma 7.1. For any \( g \in \text{GL}_2(\mathbb{Z}/\mathbb{N}\mathbb{Z}) \) we have
\[
g^*\text{Eis}_D^{n}(u) = \text{Eis}_D^{n}(ug),
\]
\[
g^*\text{Eis}_{\text{hol}}^{n}(u) = \text{Eis}_{\text{hol}}^{n}(ug).
\]

Proof. In the case \( n \geq 1 \), this is a direct consequence of Deninger’s definition, while in the case \( n = 0 \) this follows from the transformation property of Siegel units given in §5.1.

Definition 7.1. Let \( p : E(N) \to Y(N) \) be the projection map. Let \( u, v \in (\mathbb{Z}/\mathbb{N}\mathbb{Z})^2 \), with \( u \neq (0,0) \). We define the Deninger–Scholl element \( \text{Eis}_{\text{D}}^{0,1}(u,v) := (p^*\text{Eis}_{\text{D}}^0(u)) \cup \text{Eis}_1(v) \in H_3^3(E(N), \mathbb{Q}(3)) \).

In [12, §6] we defined a canonical differential 2-form \( \text{Eis}_{\text{D}}^{0,1}(u,v) \) on \( E(N)(\mathbb{C}) \) representing the regulator of \( \text{Eis}_{\text{D}}^{0,1}(u,v) \). We split \( \text{Eis}_{\text{D}}^{0,1}(u,v) \) into a sum \( \eta_{u,v}^1 + \eta_{u,v}^2 \), where
\[
\eta_{u,v}^1 = p^*\text{Eis}_D^0(u) \cdot \pi_2(\text{Eis}_{\text{hol}}^1(v)),
\]
\[
\eta_{u,v}^2 = -p^*\pi_1(\text{Eis}_{\text{hol}}^0(u)) \wedge \text{Eis}_D^1(v).
\]

It is convenient to extend the definition of Eisenstein symbols linearly as follows. For \( \phi \in \mathbb{C}[(\mathbb{Z}/\mathbb{N}\mathbb{Z})^2 \times (\mathbb{Z}/\mathbb{N}\mathbb{Z})^2] \) such that \( \phi((0,0), v) = 0 \) for all \( v \in (\mathbb{Z}/\mathbb{N}\mathbb{Z})^2 \), we define
\[
\text{Eis}_{\text{D}}^{0,1}(\phi) = \sum_{u,v} \phi(u,v)\text{Eis}_{\text{D}}^{0,1}(u,v).
\]

We define \( \eta_{\phi}^1 \) and \( \eta_{\phi}^2 \) analogously.

The following lemma is an immediate consequence of Lemma 7.1.

Lemma 7.2. For any \( g \in \text{GL}_2(\mathbb{Z}/\mathbb{N}\mathbb{Z}) \)
\[
g^*\text{Eis}_{\text{D}}^{0,1}(u,v) = \text{Eis}_{\text{D}}^{0,1}(ug, vg),
\]
\[
g^*\text{Eis}_{\text{hol}}^{0,1}(u,v) = \text{Eis}_{\text{hol}}^{0,1}(ug, vg).
\]

Introducing a right \( \text{GL}_2(\mathbb{Z}/\mathbb{N}\mathbb{Z}) \)-action on \( \mathbb{C}[(\mathbb{Z}/\mathbb{N}\mathbb{Z})^2 \times (\mathbb{Z}/\mathbb{N}\mathbb{Z})^2] \) by setting \( \phi(g(u,v)) = \phi(ug^{-1}, vg^{-1}) \), Lemma 7.2 can be rephrased as \( g^*\text{Eis}_{\text{D}}^{0,1}(\phi) = \text{Eis}_{\text{D}}^{0,1}(\phi|g) \).

Proposition 7.3.

1. For all integers \( m, n \in \mathbb{Z} \) the integral \( \int_{(mX+nY)(0,\infty)} \eta_{u,v}^2 \) converges absolutely.
2. If \( \phi \in \mathbb{C}[(\mathbb{Z}/\mathbb{N}\mathbb{Z})^2 \times (\mathbb{Z}/\mathbb{N}\mathbb{Z})^2] \) satisfies
\[
\sum_{u,v \in (\mathbb{Z}/\mathbb{N}\mathbb{Z})^2} \phi(u,v)B_2(\{u_1/N\})B_3(\{v_1/N\}) = 0
\]
and
\[
\sum_{u,v \in (\mathbb{Z}/\mathbb{N}\mathbb{Z})^2} \phi(u,v) \log |1 - \zeta_N^{u_1}|B_3(\{v_1/N\}) = 0,
\]
then \( \int_X^{(0,\infty)} \eta_{\phi}^1 \) converges absolutely.
3. If \( \phi|\sigma \) satisfies conditions 13 and 14, then \( \int_Y^{(0,\infty)} \eta_{\phi}^1 \) converges absolutely.
Proof. We start with item (2). The strategy is to first compute the integral of $	ext{Eis}_D^{0,1}(u, v)$ along the fibers of the fibration $p_Q : Q\{0, \infty\} \to \{0, \infty\}$. Using [12, Prop. 8.1], we get

\begin{equation}
\int_{p_Q} \eta^1_{u,v} = \text{Eis}_D^0(u) \cdot - \frac{6\pi^2}{N} \left( F_{v}^{(3)}(\tau) d\tau + \overline{F_{v}^{(3)}(\tau)} d\tau \right),
\end{equation}

so we need to show that the integral

\begin{equation}
\int_0^\infty \left| \sum_{u,v \in (\mathbb{Z}/N\mathbb{Z})^2} \phi(u,v) \text{Eis}_D^0(u) \cdot \left( F_{v}^{(3)}(iy) + \overline{F_{v}^{(3)}(iy)} \right) \right| dy
\end{equation}

converges. The Fourier expansion of $\text{Eis}_D^0(u)$ can be deduced from [11, Lemma 16]

\[ \text{Eis}_D^0(u) = \frac{2}{N} \log |g_u| = \frac{2}{N} \Re \left( \pi i B_2 \left( \frac{a}{N} \right) \tau + \delta_0(a) \log(1 - \zeta^b_N) + \sum_{n \geq 1} c_n q^{n/N} \right). \]

In particular, $\text{Eis}_D^0(u)$ grows at most polynomially for $y \to \infty$. The Fourier expansion of $F_{v}^{(3)}(\tau)$ is given in [12, Lemme 3.3]. It has the constant term $-\text{B}_2((-\omega_(\mathbb{Z}/N\mathbb{Z})))$, so the conditions on $\phi$ are equivalent to the assumption that the integrand in (16) decays exponentially for $y \to \infty$. Using [12, Lemme 3.3], we can also determine the Fourier expansion of $W_N F_{v}^{(3)}(\tau) = -iN^{3/2}\tau^{-3} F_{v}^{(3)}(-1/(N\tau))$. It has the constant term $-iN^{3/2}(v_2/N, -2)$, which implies that $F_{v}^{(3)}(iy) + F_{v}^{(3)}(iy)$ decays exponentially for $y \to 0$. The rest of the integrand can in fact be bounded for $y \to 0$, so this concludes the proof in which (16) is absolutely convergent. The third statement in the proposition follows from Lemmas 4.2 and 7.2.

To show the absolute convergence of $\int_{Q\{0, \infty\}} \eta^2_{u,v}$, we calculate

\begin{equation}
\int_{p_Q} \eta^2_{u,v} = -\pi_1(\text{Eis}_D^{0,1}(u)) \cdot \frac{3}{2\pi i N} iy \left( F_{\sigma_v}^{0,1}(\tau)(m\tau + n) + F_{\sigma_v}^{1,0}(\tau)(m\tau + n) \right),
\end{equation}

where

\[ \pi_1 \text{Eis}_D^{0,1}(u) = - \frac{2i\pi}{N} (F_{-u}^{(2)}(\tau) d\tau + \overline{F_{-u}^{(2)}(\tau)} d\tau). \]

Restricted to $\{0, \infty\}$, the differential form $\pi_1 \text{Eis}_D^{0,1}(u)$ becomes $ \frac{2i\pi}{N} (F_{-u}^{(2)}(iy) - F_{-u}^{(2)}(iy)) dy$, and similar calculations as used before show that $F_{-u}^{(2)}(iy) - F_{-u}^{(2)}(iy)$ decays exponentially for $y \to \infty$ and $y \to 0$. \qed

Even if absolute convergence is given, some further care is needed when integrating Eisenstein symbols: contrary to what [11, Remark 2] and [12, Remarque 1.2(iii)] suggest, it is not true in general that if $\omega$ is a closed differential 2-form on $E(N)(\mathbb{C})$ and $\alpha, \beta, \gamma$ are cusps, then $\int_{P(\alpha,\beta)} \omega + \int_{P(\beta,\gamma)} \omega = \int_{P(\alpha,\gamma)} \omega$. The reason for this is that $\omega$ may have nontrivial residues at the cusps. This leads to the following definition.

**Definition 7.2.** Let $n \geq 1$ be an integer, and let $\omega$ be a closed differential $n$-form on $E(N)^{n-1}(\mathbb{C})$. We say that $\omega$ has trivial residues at the cusps if for every $g \in \text{GL}_2(\mathbb{Z}/N\mathbb{Z})$, every $Q \in \mathbb{Z}[X,Y]_{n-1}$, and every $\alpha \in \mathbb{R}$, we have

\[ \int_{Q(iy,\alpha+iy)} g^* \omega \xrightarrow{y \to \infty} 0. \]
Example 7.1. In the case \( n = 1 \), let \( u, v \) be modular units on \( Y(N)(\mathbb{C}) \) such that the Milnor symbol \( \{u, v\} \) has trivial tame symbols at all cusps. Then the 1-form \( \eta(u, v) = \log |u|d\arg(v) - \log |v|d\arg(u) \) has trivial residues at the cusps.

Remark. In general, let us consider the differential form \( \omega = \text{Eis}_D^{k_1,k_2}(u,v) \) from [12] §6. The property of \( \omega \) having trivial residues at the cusps is probably related to the motivic element \( \text{Eis}^{k_1,k_2}(u,v) \) extending to Deligne’s smooth compactification of \( E(N)^{k_1+k_2} \), but we will not need this property in this article.

Proposition 7.4. Let \( u = (a,b) \in (\mathbb{Z}/N\mathbb{Z})^2, u \neq (0,0) \), and \( v = (c,d) \in (\mathbb{Z}/N\mathbb{Z})^2 \).

We have

\[
\lim_{y \to \infty} \int_{X \{iy, \alpha + iy\}} \text{Eis}_D^{0,1}(u,v) = -\frac{4\pi^2}{N^2} \delta_0(a) \log |1 - \zeta_N^b| B_3(\{c/N\}) \alpha^2 + \frac{3\pi i}{N^2} B_2(\{a/N\}) \delta_0(c) \left( \tilde{\zeta}(d/N, 2) - \tilde{\zeta}(d/N, 2) \right) \alpha,
\]

\[
\lim_{y \to \infty} \int_{X \{iy, \alpha + iy\}} \text{Eis}_D^{0,1}(u,v) = -\frac{8\pi^2}{N^2} \delta_0(a) \log |1 - \zeta_N^b| B_3(\{c/N\}) \alpha.
\]

Proof. Again we first compute the integral of \( \text{Eis}_D^{0,1}(u,v) \) along the fibers of the fibration \( p_{Q, \alpha} : Q\{iy, \alpha + iy\} \to \{iy, \alpha + iy\} \). We start from equation (15) with \( p_X \) replaced with \( p_{X, \alpha} \) and integrate from \( \tau = iy \) to \( \tau = \alpha + iy \). Since every term involving \( q_{n/N} = \exp(2\pi i \tau/N) \) with \( n \geq 1 \) will vanish when taking the limit as \( y \to \infty \), this gives

\[
\int_{X \{iy, \alpha + iy\}} \eta_{u,v} = \frac{8\pi^2}{N^2} B_2(\{c/N\}) \left( -\pi B_2(\{a/N\})y + \delta_0(a) \log |1 - \zeta_N^b| \alpha^2 + o_{y \to \infty}(1) \right).
\]

The integral of \( \eta_{u,v} \) can be computed similarly, using the Fourier expansions [12 Lemma 3.3, Prop. 8.1] and [12 Prop. 8.4]. We get

\[
\int_{X \{iy, \alpha + iy\}} \eta_{u,v} = \frac{3}{2N^2} B_2(\{c/N\}) \left( -\frac{8\pi^3}{3} B_3(\{c/N\}) \alpha^2 + 2\pi i \delta_0(c) \left( \tilde{\zeta}(d/N, 2) - \tilde{\zeta}(d/N, 2) \right) \alpha \right) + o_{y \to \infty}(1).
\]

Adding (20) and (21), the terms in \( y \) cancel out, giving (18). The identity (19) follows from a similar computation. \( \square \)

Corollary 7.5. Let \( b, b', d \in \mathbb{Z}/N\mathbb{Z} \) such that \( d \) is a multiple of both \( b \) and \( b' \). Suppose furthermore that \( b \equiv \pm b' \mod \gcd(d,N) \). Then the form

\[
\text{Eis}_D^{0,1}((0,b),(0,d)) - \text{Eis}_D^{0,1}((0,b'),(0,d))
\]

has trivial residues at the cusps.

Proof. Let \( \left( \frac{u}{w}, \frac{v}{w} \right) \in \text{GL}_2(\mathbb{Z}/N\mathbb{Z}) \). We need to show that the two limits calculated in Proposition 7.4 vanish for the form \( \text{Eis}_D^{0,1}((bw,bz),(dw,dz)) - \text{Eis}_D^{0,1}((b'w,b'z),(dw,dz)) \). If either \( bw \) or \( b'w \) is zero, then \( dw \) is zero since \( d \) is a multiple of \( b \) and \( b' \). This implies that the limit (19) vanishes and only the second term of (18) remains.
If this term is nonzero, then we must have $dw = 0$, so $\frac{N}{gcd(d,N)}|w$. By our assumptions this implies that $bw = \pm b'|w \mod N$, so $B_2(\{bw/N\}) = B_2(\{b'w/N\})$ and the contributions of $\text{Eis}_{D}^{0,1}((bw,bz),(dw,dz))$ and $\text{Eis}_{D}^{0,1}((b'w,b'z),(dw,dz))$ to (18) cancel each other out. □

8. Calculation

We first express the Mahler measure of $P = X + \frac{1}{X} + Y + \frac{1}{Y} + Z + \frac{1}{Z} - 2$ as the integral of a closed differential form on $E_1(8)(\mathbb{C})$.

By Lemma 13.1 we may identify the Deninger cycle $D'_p = D_p \setminus \{(-1, -1, 3 + 2\sqrt{2})\}$ with a cycle on $E_1(8)(\mathbb{C})$.

Note that for every $b \in \mathbb{Z}/N\mathbb{Z}$, $b \neq 0$, and every $d \in \mathbb{Z}/N\mathbb{Z}$, the 2-form $\text{Eis}_{D}^{0,1}((0, b), (0, d))$ descends to a form on $E_1(N)(\mathbb{C})$.

Lemma 8.1. We have

$m(P) = \pm \frac{1}{(2\pi i)^2} \int_{D'_p} \eta_1,$

where $\eta_1$ is the closed 2-form on $E_1(8)(\mathbb{C})$ defined by

$\eta_1 = \frac{2\pi}{3} \left( \text{Eis}_{D}^{0,1}((0, 3), (0, 2)) - \text{Eis}_{D}^{0,1}((0, 1), (0, 2)) \right).$

Proof. Since $P^* = 1$, Jensen’s formula (2) gives

$m(P) = \frac{1}{(2\pi i)^2} \int_{D'_p} \log|Z| \frac{dX}{X} \wedge \frac{dY}{Y}.$

Since $m(P)$ is real, we may write

$m(P) = \frac{1}{(2\pi i)^2} \int_{D'_p} \log|Z| \pi_2 \left( \frac{dX}{X} \wedge \frac{dY}{Y} \right).$

Let $\Omega^2(E_1(8)(\mathbb{C}))$ be the space of holomorphic 2-forms on $E_1(8)(\mathbb{C})$. There is a well-defined map

$H^2_D(E_1(8)(\mathbb{C}), \mathbb{R}(2)) \rightarrow \Omega^2(E_1(8)(\mathbb{C}))$

sending the class of a 1-form $\phi$ to the unique holomorphic form $\omega$ such that $d\phi = \pi_1(\omega)$. By Proposition 11.12 we have $\{X, Y\} = \pm (64/3)\text{Eis}_1(0, 2)$ in $H^2_D(E_1(8), \mathbb{Q}(2))$. Taking regulators and applying the above map, we see that

$\frac{dX}{X} \wedge \frac{dY}{Y} = \pm \frac{64}{3} \text{Eis}_1^1(0, 2).$

Since $Z$ takes positive real values on $D$, the form $\pi_1(dZ/Z) = i \text{darg}(Z)$ vanishes on $D'_p$. We thus have

$m(P) = \frac{1}{(2\pi i)^2} \int_{D'_p} \log|Z| \pi_2 \left( \pm \frac{64}{3} \text{Eis}_1^1(0, 2) \right) - \pi_1 \left( \frac{dZ}{Z} \right) \wedge \pm \frac{64}{3} \text{Eis}_1^1(0, 2).$

It remains to express $\log|Z|$ and $dZ/Z$ in terms of Eisenstein symbols using Propositions 5.3 and 5.4. Letting $p_1 : E_1(8) \rightarrow Y_1(8)$, we have

$\log|Z| = p_1^* \left( 8(\text{Eis}_D^0(0, 3) - \text{Eis}_D^0(0, 1)) \right),$

$\frac{dZ}{Z} = p_1^* \left( 8(\text{Eis}_1^0(0, 3) - \text{Eis}_1^0(0, 1)) \right).$

The result now follows from the definition of $\text{Eis}_{D}^{0,1}$ (see (11) and (12)). □
We now express the Mahler measure of $P$ as an integral over a suitable Shokurov cycle.

**Lemma 8.2.** The map $\tau \mapsto Z(\tau)$ induces a diffeomorphism from $\{1/2, \infty\}$ to $(1, 3 + 2\sqrt{2})$.

**Proof.** By Proposition 5.3 we have $Z(1/2 + it) \in \mathbb{R}$ for every $t > 0$. By Propositions 5.1 and 5.2 we can evaluate $Z$ at any cusp. We find that $Z(i\infty) = 3 + 2\sqrt{2}$ and $Z(1/2) = \lim_{\tau \to \infty} (g_{6,3}(it)/g_{2,1}(it))^2 = 1$. A more detailed analysis will show that $Z$ is monotonically increasing on the path $t \mapsto 1/2 + it$.

Note that $Z$ is an Hauptmodul for $\Gamma_1(8)$ and is defined over $\mathbb{R}$ so that $Z$ identifies the real points $Y_1(8)(\mathbb{R})$ with an open subset of $\mathbb{R}$. It therefore suffices to show that the canonical map $\{1/2, \infty\} \to Y_1(8)(\mathbb{R})$ is injective. This follows from the work of Snowden on real components of modular curves [28]. We use [28, Lemma 3.3.4] for the modular curve $\Gamma_1(8) \backslash \mathcal{H}$ endowed with the complex conjugation $c(\tau) = -\tau$. The matrix $\gamma = \begin{pmatrix} 1 & -1 \\ 0 & 1 \end{pmatrix} \in \Gamma_1(8)$ is admissible and $C_\gamma$ is the only element of $\Gamma_1(8)$ leaving $C_\gamma$ invariant is the identity. We may thus take $\mathcal{F} = \{1/2, \infty\}$ in [28, Lemma 3.3.4], giving the desired result. \qed

By Lemmas 2.2 and 8.2, the Deninger cycle $D'_p$ is endowed with a fibration $q : D'_p \to \{1/2, \infty\}$. Note that for every $\tau \in \{1/2, \infty\}$, the fiber $q^{-1}(\tau)$ can be identified with a closed 1-cycle on the elliptic curve $E_\tau \cong \mathbb{C}/(\mathbb{Z} + \tau \mathbb{Z})$. Since $\tau \in \{1/2, \infty\}$, the elliptic curve $E_\tau$ is defined over $\mathbb{R}$.

**Lemma 8.3.** For every $\tau \in \{1/2, \infty\}$ the class of $q^{-1}(\tau)$ generates $H_1(E_\tau, \mathbb{Z})^+$.

**Proof.** The complex conjugation $c(X, Y, Z) = (\overline{X}, \overline{Y}, \overline{Z})$ on $E_1(8)(\mathbb{C})$ leaves $D'_p$ stable and preserves its orientation. Since $c$ fixes pointwise the cycle $\{1/2, \infty\}$ on $Y_1(8)(\mathbb{C})$, we deduce that $c$ leaves $q^{-1}(\tau)$ stable and preserves its orientation. Thus the class of $q^{-1}(\tau)$ belongs to $H_1(E_\tau, \mathbb{Z})^+$.

Let $\gamma^+_\tau : [0, 1] \to E_\tau$ denote the canonical generator of $H_1(E_\tau, \mathbb{Z})^+$, defined by $\gamma^+_\tau(t) = [t]$. Since the fiber $q^{-1}(\tau)$ varies continuously with $\tau$, we must have $[q^{-1}(\tau)] = m[\gamma^+_\tau]$ for some integer $m$ not depending on $\tau$.

In order to determine $m$, we introduce for every $\tau \in \{1/2, \infty\}$ the holomorphic form $\omega_\tau$ on $E_\tau$ defined by

$$\omega_\tau = \frac{dU}{2V + (Z(\tau) + \frac{1}{Z(\tau)} - 2)U}.$$  

Using the function **ellpointod** of Pari/GP or integrating $\omega_\tau$ numerically, we check that for $\tau_0 = 1/2 + i$, we have

$$\int_{q^{-1}(\tau_0)} \omega_{\tau_0} \approx \int_{\gamma^+_{\tau_0}} \omega_{\tau_0}.$$  

Since we know a priori that $m$ is an integer, we deduce that $m = 1$. \qed

In view of Lemma 8.3, we are naturally led to search for a Shokurov cycle on $E_1(8)(\mathbb{C})$ sharing the same properties with $D'_p$. By definition, the Shokurov cycle $Y \{1/2, \infty\}_1$ does the job: it is endowed with a fibration over $\{1/2, \infty\}$, and its fiber over $\tau$ is equal to $\gamma^+_\tau$.  

Proposition 8.4. We have

$$\int_{D'_p} \eta_1 = \int_{Y \{1/2, \infty \}} \eta_1.$$  

Proof. By integrating over the fibers of \( q : D'_p \to \{1/2, \infty \}, \) we get

$$\int_{D'_p} \eta_1 = \int_{1/2}^{\infty} \int_q \eta_1.$$  

Similarly, using the fibration \( p_Y : Y \{1/2, \infty \} \to \{1/2, \infty \}, \) we have

$$\int_{Y \{1/2, \infty \}} \eta_1 = \int_{1/2}^{\infty} \int_{p_Y} \eta_1.$$  

By Lemma 8.3 the fibers \( q^{-1}(\tau) \) and \( p_Y^{-1}(\tau) \) are homologous, hence \( \int_q \eta_1 = \int_{p_Y} \eta_1. \)

Pulling back \( \eta_1 \) to \( E(8)(\mathbb{C}) \), we define

$$\eta = \tilde{\pi}^* \eta_1 = \frac{9}{3} \left( \text{Eis}^0_{D}((0, 3), (0, 2)) - \text{Eis}^0_{D}((0, 1), (0, 2)) \right).$$

Using Lemma 4.1 we get

$$m(P) = \pm \frac{1}{(2\pi i)^2} \int_{Y \{1/2, \infty \}} \eta.$$  

In order to proceed further, we decompose the modular symbol \( Y \{1/2, \infty \} \) as a sum of Manin symbols of the form \( g_* (X \{0, \infty \}) \), with \( g \in \text{GL}_2(\mathbb{Z}/8\mathbb{Z}) \). We have

\[
Y \left\{ \frac{1}{2}, \infty \right\} = Y \left\{ \frac{1}{2}, 0 \right\} + Y \{0, \infty \} \\
= \begin{pmatrix} 0 & -1 \\ 1 & -2 \end{pmatrix} \cdot (X - 2Y) \{0, \infty \} - \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \cdot X \{0, \infty \} \\
= \begin{pmatrix} 0 & -1 \\ 1 & -2 \end{pmatrix} \cdot X \{0, \infty \} + 2 \begin{pmatrix} -1 & 0 \\ -2 & -1 \end{pmatrix} \cdot X \{0, \infty \} - \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix} \cdot X \{0, \infty \}.
\]

At this point we face two problems. Firstly, the integrals of \( \eta \) over the Shokurov cycles \( Y \{1/2, 0 \} \) and \( Y \{0, \infty \} \) do not converge absolutely. Secondly, we must prove that the integral of \( \eta \) over a sum of modular symbols is equal to the sum of the integrals of \( \eta \) over these modular symbols (whenever these integrals are convergent).

In order to overcome these issues, we consider the hyperbolic ideal triangle with vertices 0, 1/2, and \( \infty \), and we truncate it by cutting along horocycles centered at these cusps. We get the hexagon shown below.
Since $\eta$ is closed, Stokes’s theorem on the domain $AA'BB'CC''$ implies that
$$\left(\int_{Y(A,A')} + \int_{Y(A',B)} + \int_{Y(B',B')} + \int_{Y(B',C')} + \int_{Y(C,C')} + \int_{Y(C',A)}\right) \eta = 0.$$ 

By Corollary 7.5, the 2-form $\eta$ has trivial residues at the cusps. It follows that when $A, A', B, B', C, C'$ approach the cusps, we have
$$\lim \int_{Y(A',B)} \eta = \lim \int_{Y(B',C')} \eta = \lim \int_{Y(C',A)} \eta = 0,$$
so
$$\int_{Y(1/2,\infty)} \eta = \lim \left( \int_{Y(B',C')} \eta + \int_{Y(B',B)} \eta \right).$$

We now apply suitable matrices of $\text{SL}_2(\mathbb{Z})$ in order to reduce to integrals over the domain $X\{0,\infty\}$ as in (23). Using Lemmas 4.2 and 4.3, we get
$$\int_{Y(1/2,\infty)} \eta = \lim_{y \to \infty} \int_{X\{i/y, iy\}} \eta',$$
with
$$\eta' = \begin{pmatrix} 0 & -1 \\ 1 & -2 \end{pmatrix}^* \eta + 2 \begin{pmatrix} -1 & 0 \\ -2 & -1 \end{pmatrix}^* \eta - \begin{pmatrix} 0 & -1 \\ 1 & 0 \end{pmatrix}^* \eta.$$

Note that we used the fact that
$$\int_{Y(i/y,iy)} \omega = -\int_{\sigma(X\{i/y,iy\})} \omega = -\int_{X\{i/y,iy\}} \sigma^* \omega$$
for a closed 2-form $\omega$ on $E(8)(\mathbb{C})$. 
Using Corollary 7.2 we have
\[ \eta' = \frac{2^9}{3} \text{Eis}^{0,1}_D(\phi), \]
with
\[ \phi = [(3, 2), (2, 4)] - [(1, 6), (2, 4)] + 2[(2, 5), (4, 6)] - 2[(6, 7), (4, 6)] - [(3, 0), (2, 0)] + [(1, 0), (2, 0)]. \]

By Proposition 7.3 the integral of \( \text{Eis}^{0,1}_D(\phi) \) over \( X \{ 0, \infty \} \) converges absolutely.

We finally may apply the main result of [12]. More precisely, we use [12, Thm. 1.1] for the terms \([a, b], (c, d)\], with \( d \neq 0 \), and we use [12, Thm. 9.5] for the term \(-[(3, 0), (2, 0)] + [(1, 0), (2, 0)]\). We restate the two theorems in our situation. Recall the Eisenstein series
\[ G_{a,b}^{(k)} = a_0(G_{a,b}^{(k)}) + \sum_{m,n \geq 1} m^{k-1} q^{mn} + (-1)^k \sum_{m,n \geq 1} m^{k-1} q^{mn}. \]

The constant term \( a_0(G_{a,b}^{(k)}) \) is given in [12, Def. 3.5]. They are modular forms of weight \( k \) with respect to \( \Gamma_1(N^2) \), except in the case \( k = 2 \) and \( a = 0 \). However, in this case, for any \( b' \in \mathbb{Z}/N\mathbb{Z} \), the function \( G_{0,b}^{(2)} - G_{0,b'}^{(2)} \) is a modular form with respect to \( \Gamma_1(N^2) \).

**Theorem 8.5** (Theorem 1.1 of [12] for \( k_1 = 0 \) and \( k_2 = 1 \)). Let \( N \geq 3 \) and \( u = (a, b), v = (c, d) \in (\mathbb{Z}/N\mathbb{Z})^2 \), with \( u \neq (0, 0) \). If \( d \neq 0 \), then
\[
\int_{X \{ 0, \infty \}}\text{Eis}^{0,1}_D(u, v) = \frac{3}{N^3} (2\pi)^2 \Lambda^*(G_{d,a}^{(2)}G_{b,c}^{(1)} - G_{d,-a}^{(2)}G_{b,c}^{(1)}),
\]
where \( \Lambda^*(\cdot, 0) \) denotes the regularized value at \( s = 0 \) [12, Def. 3.13].

In the case \( d = 0 \), Theorem 8.5 also holds provided that one replaces \( u \) by a formal linear combination \( \sum_i \lambda_i(a_i, b) \) satisfying \( \sum_i \lambda_i = 0 \), taking the appropriate linear combination of Eisenstein series on the right-hand side of (25), see [12, Thm. 9.5].

Using Theorem 8.5, we get
\[
\int_{X \{ 0, \infty \}}\text{Eis}^{0,1}_D(\phi) = \frac{3}{N^3} (2\pi)^2 \Lambda^*(F, 0),
\]
with
\[
F = G_{4,3}^{(2)}G_{2,-2}^{(2)} - G_{4,-3}^{(2)}G_{2,2}^{(2)} - G_{4,1}^{(2)}G_{6,-2}^{(1)} + G_{4,-1}^{(2)}G_{6,2}^{(1)} + 2G_{6,2}^{(2)}G_{5,-4}^{(1)} - 2G_{6,-2}^{(2)}G_{5,4}^{(1)} - 2G_{6,6}^{(2)}G_{7,-4}^{(1)} + 2G_{6,-6}G_{7,4}^{(1)} + G_D^{(2)}G_{0,1}^{(1)}G_{0,-2}^{(2)} + (G_{0,-3}^{(2)} - G_{0,-1}^{(2)})G_{0,1}^{(2)}.
\]

We know in advance that \( F(\tau/8) \) belongs to \( M_3(\Gamma_1(8)) \) by [12, Remarque 1.2(iv)], and a computation reveals that \( F(\tau/8) = -4f(\tau) \), where
\[
f(\tau) = q - 2q^2 - 2q^3 + 4q^4 + 4q^6 - 8q^8 - 5q^9 + 14q^{11} + O(q^{12})
\]
is the unique newform of weight 3 and level \( \Gamma_1(8) \). We have
\[
\Lambda_3^*(F, 0) = -4\Lambda_3(f, 0) = -4\Lambda_3(Wsf, 3).
\]

**Lemma 8.6.** We have \( Ws f = f \).
Proof. Since $S_3(\Gamma_1(8))$ is 1 dimensional, we have $W_8 f = \varepsilon f$, with $\varepsilon \in \{ \pm 1 \}$. Evaluating numerically $f$ and $W_8 f$ at $\tau = i/\sqrt{8}$, we get $\varepsilon = 1$. $\square$

It follows that
\begin{equation}
\Lambda^*(F,0) = -4\Lambda(f,3).
\end{equation}

Putting (22), (24), (26), and (27) together, we obtain
\begin{equation*}
m(P) = \pm \frac{1}{(2\pi i)^2} (2\pi)^2 \cdot -4\Lambda(f,3) = \pm 4\Lambda(f,3).
\end{equation*}

Since $m(P)$ and $\Lambda(f,3)$ are positive real numbers, we conclude that $m(P)$ is equal to $4\Lambda(f,3)$.

9. Other examples

In this section we compute several more Mahler measures of models of elliptic surfaces in terms of $L$-values. Suppose that we have an affine model of an elliptic modular surface $E = E(\Gamma)$ defined by a polynomial $P(X,Y,Z) \in \mathbb{C}[X,Y,Z]$ and an elliptic fibration given by $(X,Y,Z) \mapsto Z$. The method we developed relies on several properties of the fibration.

1. The horizontal divisors of $X$ and $Y$ are supported in the torsion sections of $E$ and the Milnor symbol $\{X,Y\}$, a priori defined on the complement of the torsion sections, extends to an element of $H^2_M(E,\mathbb{Q}(2)) = K^2_2(E)$.

2. The function $Z$ is the pullback of a modular unit on the modular curve $X(\Gamma)$.

3. The function $Z$ takes real values on the Deninger cycle $D_P = \{(X,Y,Z) \in V(P) : |X| = |Y| = 1, \ |Z| > 1\}$, and $D_P$ is fibered over an interval $(a,b) \subset \mathbb{R}$, where $a$ and $b$ are cusps of $X(\Gamma)$.

Remark. More generally, it seems that our method could also work when the parametrization $\phi : E(\Gamma) \rightarrow V(P)$ is a dominant map (not necessarily a birational isomorphism). In this case, the relevant condition would be that the Deninger cycle $D_P$ is homologous to the push-forward of a Shokurov cycle.

In order to find good candidate polynomials $P$, we proceed as follows. We look for functions $X,Y$ on the elliptic surface $E$ whose divisors are supported in the torsion subgroup of $E$. Given $X$ and $Y$, we compute the tame symbols of $\{X,Y\}$ along the torsion sections and check whether there exist modular units $u$ and $v$ such that $\{uX,vY\}$ extends to an element of $H^2_M(E,\mathbb{Q}(2)) = K^2_2(E)$. Once the functions $X,Y$ are found, we compute the minimal polynomial $P$ of $(X,Y,Z)$, and we try to adjust the modular unit $Z$ such that condition (3) is satisfied. Note however that in some cases, like the universal elliptic curve for $\Gamma_1(7)$, the search for $X,Y$ was unsuccessful.

Given the three conditions above, we can follow the method described in the previous sections and find that $m(P) - m(P^*)$ equals $\Lambda(F,0)$ for an explicit modular form $F \in \mathcal{M}_3(\Gamma)$ with rational Fourier coefficients. It is not always the case that $F$ is a cusp form, and in the examples that follow we see that $F$ can be an Eisenstein series or a combination of an Eisenstein series and a cusp form. For that reason we briefly recall a standard basis for the Eisenstein subspace of $\mathcal{M}_3(\Gamma_1(1))$, i.e., the orthogonal complement of $S_3(\Gamma_1(1))$ with respect to the Petersson inner product.
Definition 9.1. A basis for the Eisenstein subspace of $\mathcal{M}_3(\Gamma_1(N))$ is given by

$$E_3^{\phi,\psi,t}(\tau) = \delta_{N_1,1} L(\psi, -2) + 2 \sum_{m,n \geq 1} \phi(m)\psi(n)n^2q^{mn}$$

for all primitive characters $\phi, \psi$ modulo $N_1, N_2$ such that $\phi(-1)\psi(-1) = -1$ and all $t \in \mathbb{N}$ such that $N_1N_2t$ divides $N$. The completed $L$-function of $E_3^{\phi,\psi,t}$ equals

$$\Lambda(E_3^{\phi,\psi,t}, s) = 2t^{-s}N^{s/2}(2\pi)^{-s}\Gamma(s)L(\phi, s)L(\psi, s - 2).$$

9.1. Another example for $\Gamma_1(8)$. We start with another example for the group $\Gamma_1(8)$. Defining

$$x(U, V) = \frac{1}{U}, \quad y(U, V) = \frac{(Z - 1)^2U}{ZV} + 1$$

we get a birational map from the surface defined by (3), i.e., $V^2 + (Z + \frac{1}{Z} - 2)UV = U(U - 1)^2$, to the surface $V(Q)$, where

$$Q(x, y, Z) = (x - 1)^2(y - 1)^2 - \frac{(Z - 1)^4}{Z^2}xy.$$ 

Since $V(P)$ and $V(Q)$ are birational, the surface $V(Q)$ is a model for $E_1(8)$. The Deninger cycle $D_Q = \{(x, y, Z) \in V(Q) : |x| = |y| = 1, |Z| > 1\}$ associated with $Q$ is very similar to the one we studied in the previous sections. In particular, we have the same fibration as before.

Lemma 9.1. The map $(x, y, Z) \mapsto Z$ defines a fibration of $D_Q \setminus \{(-1, -1, 3+2\sqrt{2})\}$ above the interval $(1, 3 + 2\sqrt{2})$.

Proof. Let $(x, y, Z) \in V(Q)$. So

$$\frac{(x - 1)^2}{x} \cdot \frac{(y - 1)^2}{y} = \left(\frac{(Z - 1)^2}{Z}\right)^2.$$

As in the proof of Lemma 2.1 we can conclude that for $x, y \in S^1$ and $|Z| > 1$ this implies $Z \in (1, 3 + 2\sqrt{2})$. □

The functions $x$ and $y$ on $E_1(8)$ have horizontal divisors

$$\operatorname{div}(x) = 2(0) - 2(4A), \quad \operatorname{div}(y) = 2(2A) - 2(6A).$$

Note that the divisors of $x$ and $y$ are disjoint. This implies that the horizontal tame symbols of $\{x, y\}$ are trivial, and thus $\{x, y\}$ defines an element of $H^2_\mathcal{M}(E_1(8), \mathbb{Q}(2))$. Since the elliptic involution maps $(x, y)$ to $(x, 1/y)$, the symbol $\{x, y\}$ belongs to $H^2_\mathcal{M}(E_1(8), \mathbb{Q}(2))^-$. Furthermore,

$$\pi^*\{x, y\} = \pm(128/3) \cdot \operatorname{Eis}^1(0, 2) = 2\pi^*\{X, Y\},$$

where $\pi$ is the projection from $E(8)$ to $E_1(8)$. Using the fact that $D_Q$, just as $D_P$, is fibered above $(1, 3 + 2\sqrt{2})$, we can follow the method from the last section and write

$$m(Q) = \pm \frac{1}{(2\pi)^2} \int_{Y\{1/2, \infty\}} 2\eta,$$

where $\eta$ is defined as in the previous section. Hence we get the following exotic relation between $m(P)$ and $m(Q)$.

Theorem 9.2. We have

$$m(Q) = 8\Lambda(f_8, 3) = 2m(P).$$
9.2. The surface $E(\Gamma_1(4) \cap \Gamma_0(8))$. According to Bertin and Lecacheux [5, 7.1], a model of the elliptic modular surface $E(\Gamma)$ associated with the group $\Gamma = \Gamma_1(4) \cap \Gamma_0(8)$ is given by $X + 1/X + Y + 1/Y = k$, and the elliptic fibration is given by $(X, Y, k) \rightarrow k$. The functions $X$ and $Y$ are supported at the torsion sections of $E(\Gamma)$, and the Milnor symbol $\{X, Y\}$ extends to $E(\Gamma)$. The function $k$ is a Hauptmodul for $\Gamma$, and the values of $k$ at the cusps are given by $\{\infty, 0, 4, -4\}$, so $k$ is a modular unit. However, condition (3) is not satisfied: the image of the Deninger cycle under $k$ is given by $[-4, -1) \cup (1, 4]$ and the endpoints $k = \pm 1$ are not cusps. We thus look for another modular unit. Putting $k = 4(t + 1)$, the cusps are given by $t \in \{\infty, -1, 0, -2\}$, so $t$ is again a modular unit, and the image of the Deninger cycle under $t$ is given by the interval $[-2, -1)$, which joins two cusps. We thus investigate the Mahler measure of the polynomial

$$R(X, Y, t) = X + \frac{1}{X} + Y + \frac{1}{Y} - 4t - 4.$$ 

In terms of the modular unit $Z$ from the $\Gamma_1(8)$ case, we have $k = -Z - 1/Z + 2$ and thus $4t = -Z - 1/Z - 2$. Using Proposition 5.2 we find the values of $t$ at the cusps of $\Gamma$, which are represented by $\tau = \infty, 0, 1/4, 1/2$: $t(\infty) = -2, t(0) = \infty, t(1/4) = 0, t(1/2) = -1$. The divisor of $t$ is thus $(1/4) - (0)$, from which we find

$$4t = i \cdot \frac{g_6^3 g_{6,4}^4}{g_{0,1}^4 g_{0,3}^4} = 24\text{Eis}^0(0, 2) + 8\text{Eis}^0(0, 4) - 16\text{Eis}^0(0, 1) - 16\text{Eis}^0(0, 3).$$

Letting $\pi$ be the canonical map $E_1(8) \rightarrow E(\Gamma)$, we have as in Proposition 5.12

$$\pi^*\{X, Y\} = \pm \frac{64}{3} \cdot \text{Eis}^1(0, 2).$$

Jensen’s formula gives

$$m(R) - \log 4 = \frac{1}{(2\pi i)^2} \int_{D_R} \log |t| \frac{dX}{X} \wedge \frac{dY}{Y}.$$ 

The map $(X, Y, t) \mapsto (X, Y)$ identifies $D_R$ with the subset of the torus $T^2$ defined by the condition $\text{Re}(X + Y) < 0$, hence

$$\int_{D_R} \frac{dX}{X} \wedge \frac{dY}{Y} = \frac{1}{2} \int_{T^2} \frac{dX}{X} \wedge \frac{dY}{Y} = \frac{1}{2}(2\pi i)^2.$$ 

It follows that

$$m(R) - \log 4 = \frac{1}{(2\pi i)^2} \int_{D_R} \log |4t| \frac{dX}{X} \wedge \frac{dY}{Y} - \frac{1}{2} \log 4.$$ 

As in 8, the Deninger cycle $D_R$ is homologous to $Y(1/2, \infty)$, and similar computations give

$$m(R) = \log 2 + \Lambda^* (4\text{Eis}^{\chi_4,1,1} - 32\text{Eis}^{\chi_4,1,2}, 0),$$

where $\chi_4$ is the nontrivial Dirichlet character of conductor 4. Using 28, we get

$$\Lambda(\text{Eis}^{\chi_4,1,1}, 0) = \Lambda(\text{Eis}^{\chi_4,1,2}, 0) = 2L(\chi_4, 0)\zeta'(-2) = -\frac{\zeta(3)}{4\pi^2}.$$ 

This gives the following theorem.

**Theorem 9.3.** We have

$$m(R) = \log 2 + \frac{7\zeta(3)}{\pi^2}.$$
9.3. The surface $E_1(6)$. In contrast to $E_1(8)$, the surface $E_1(6)$ is not a K3 surface but a rational surface. This is equivalent to the fact that $\mathcal{S}_3(\Gamma_1(6)) = \{0\}$. We will show that the Mahler measure of a suitable model of $E_1(6)$ is the $L$-value of an Eisenstein series for $\Gamma_1(6)$.

An affine model for the universal elliptic curve for $\Gamma_1(6)$ can be found in [30], Table 1, [6, §4],

$$P_6(x, y, s) = s - (x + y + 1) \left( \frac{1}{x} + \frac{1}{y} + 1 \right) = 0,$$

and the universal 6-torsion point is given by $A = (-1, 0)$. The birational transformation

$$(x, y) = \left( \frac{2Y + X(s - 1)}{2X(1 - X)}, \frac{-2Y + X(s - 1)}{2X(1 - X)} \right),$$

$$(X, Y) = \left( \frac{x + y - s + 1}{x + y}, \frac{(s - 1)(x - y)(x + y - s + 1)}{2(x + y)^2} \right)$$

puts $V(P_6)$ into the Weierstrass form

$$E_s : Y^2 = X^3 + \frac{(s - 3)^2 - 12}{4} X^2 + sX$$

and $(X(A), Y(A)) = (s, \frac{1}{2}(s^2 - s))$. The functions $x$ and $y$ have horizontal divisors

$$\text{div}(x) = (0) - (2A) - (3A) + (5A), \quad \text{div}(y) = (0) + (A) - (3A) - (4A).$$

We can follow the method in [30] to find a birational map from $E_1(6)$ to $V(P_6)$:

$$X = \frac{\varphi_\tau(z) - \varphi_\tau(1/2)}{\varphi_\tau(1/3) - \varphi_\tau(1/2)},$$

$$Y = \frac{(\varphi_\tau(z) - \varphi_\tau(1/3))^2(\varphi_\tau(z + 1/3) - \varphi_\tau(z - 1/3))}{2(\varphi_\tau(1/3) - \varphi_\tau(1/6))(\varphi_\tau(1/3) - \varphi_\tau(1/2))^2},$$

$$s = \frac{\varphi_\tau(1/6) - \varphi_\tau(1/2)}{\varphi_\tau(1/3) - \varphi_\tau(1/2)} = -\frac{6}{6} \frac{g_{0,2}(\tau)^4}{g_{0,1}(\tau)^4}.$$

The function $s$ is a Hauptmodul for $\Gamma_1(6)$. From its expression as a quotient of Siegel units, we get

$$\pi^*s = 12 \text{Eis}^0((-0, 1) + (0, 2)).$$

where $\pi$ denotes the projection map from $E(6)$ to $E_1(6)$. The values of $s$ at the cusps of $\Gamma_1(6)$ are $s(0) = \infty, s(1/2) = 1, s(1/3) = 0$, and $s(\infty) = 9$.

The elliptic involution on $V(P_6)$ maps $(X, Y)$ to $(X, -Y)$, and hence $(x, y)$ to $(y, x)$. Hence we can proceed as in Proposition 6.10 and deduce that

$$\pi^* \{x, y\} = \pm 12 \text{Eis}^1((-0, 1) + (0, 2)).$$

Lemma 9.4. The fibration $(x, y, s) \mapsto s$ restricts to a fibration of Deninger cycle

$$(x, y, s) \in V(P_6) : |x| = |y| = 1, \ |s| > 1 \setminus \{(1, 1, 9)\}$$

above $(1, 9)$.

Proof. For $(x, y, s) \in V(P_6)$ the assumption $x, y \in S^1$ implies $s = 1 + 2\text{Re}((x + 1)(\overline{y} + 1))$, so $s \in (1, 9)$ and $s = 9$ is only attained at the excluded point $(1, 1, 9)$. □

The points $s = 1$ and $s = 9$ correspond to $\tau = \frac{1}{2}$ and $\tau = \infty$. Hence as before, we can conclude that

$$m(P_6) = \pm \frac{1}{(2\pi i)^2} \int_{Y_{1/2, \infty}}^{12^2 \text{Eis}^{0,1}((-0, 1) - (0, 2))((-0, 1) + (0, 2))}. $$
The main theorem of [12] implies that \( m(P_0) = \frac{1}{32} \Lambda^*( -432E_{X^3-1} + 3456E_{X^{3,1,2}}, 0 ) \), where \( \chi_3 \) is the nontrivial Dirichlet character of conductor 3. Using (28), we arrive at the following theorem.

**Theorem 9.5.** We have

\[
m(P_0) = \frac{7\zeta(3)}{\pi^2}.
\]

**Remark.** The value \( 7\zeta(3)/(2\pi^2) \) appeared first as the Mahler measure of \( 1 + X + Y + Z \), as shown by Smyth; see [17]. It also appears in several Mahler measures of elliptic surfaces as above; see [18]. For another example consider the Hesse pencil, the universal elliptic curve for \( \Gamma(3) \). By a simple change of variables we get

\[
m(X^3 + Y^3 + 1 + ZXY) = m(1 + X + Y + Z) = 7\zeta(3)/(2\pi^2).
\]

### 9.4. The surface \( E(2, 6) \)

From the model of \( E_1(6) \) we can construct a model for \( E(2, 6) \), the universal elliptic curve for the group \( \Gamma(2, 6) = \Gamma_1(6) \cap \Gamma(2) \). We look for a base change of \( E_1(6) \) of the form \( s = f(t) \) such that \( E_{f(t)} \) acquires full 2-torsion over \( \mathbb{Q}(t) \). This condition is equivalent to the polynomial \( X^2 + (s-3)^2/4X + s \) being split over \( \mathbb{Q}(t) \), which amounts to saying that

\[
s^4 - 12s^3 + 30s^2 - 28s + 9 = \frac{(s - 9)(s - 1)^3}{16}
\]

is a square in \( \mathbb{Q}(t) \). We find that the base change \( s = f(t) = 2(t + 1/5) + 5 \) does the job.

We will determine the Mahler measure of

\[
P_{2,6}(x, y, t) = P_6(x, y, 2(t+1/5)+5) = 2 \left( t + \frac{1}{t} \right) + 5 - (x+y+1) \left( \frac{1}{x} + \frac{1}{y} + 1 \right) = 0.
\]

By construction \( E'_t = E_{f(t)} \) is a Weierstrass equation for \( E_{2,6} \). The torsion subgroup of \( E'_t \) is generated by the points \( A_1, A_2 \) of orders 2, 6, respectively, given by

\[
A_1 = \left( -\frac{2t - 1}{t^2}, 0 \right),
\]

\[
A_2 = \left( \frac{2t^2 + 5t + 2}{t}, \frac{2t^4 + 9t^3 + 14t^2 + 9t + 2}{t^2} \right).
\]

Note that \( A_2 \) is the pullback of \( A \) under the base change map \( E(2, 6) \to E_1(6) \). We choose a modular parametrization that is compatible with the one we chose for \( E_1(6) \) so that \( A_1 \) corresponds to \( z = \tau/2 \) and \( A_2 \) corresponds to \( z = 1/6 \). We find that

\[
t^2 = \frac{X(A_1 + 3A_2) - X(2A_2)}{X(A_1) - X(2A_2)} = \frac{\varphi_+(\tau/2 + 1/2) - \varphi_+(1/3)}{\varphi_+\left( \frac{\tau}{2} \right) - \varphi_+(1/3)} = \frac{g_{3,1}g_{3,0}^2}{g_{3,3}g_{3,2}^2},
\]

so in \( \mathcal{O}(Y(2, 6)) \times \otimes \mathbb{Q} \) we have

\[
t = \frac{g_{3,0}g_{3,1}}{g_{3,3}g_{3,2}} = 3Ei \left( \left( \frac{3}{0} + (3, 1) - (3, 2) \right) - (3, 3) \right).
\]

Notice that knowing \( t^2 \) and \( s \) is enough to determine \( t = 2(t^2 + 1)/(s - 5) \). In particular, we may compute numerically \( t(\tau) \) without any sign ambiguity. A set of representatives of the cusps of \( \Gamma_1(6) \cap \Gamma(2) \) is given by \( \infty, 0, 1/5, 1/4, 1/3, 2/3 \).

---

\(^2\) Added in proof: Wadim Zudilin pointed out to us that Theorem 9.5 can also be proved by elementary means: the Mahler measure of \( P_6(x, y, s) \) can be reduced to the one of Smyth using Jensen’s formula with respect to \( s \).
Under $t$ these are mapped, respectively, to 1, 0, $\infty$, $-1$, $-1/2$, $-2$. Also we have $t(1/2) = -1$.

**Lemma 9.6.** Let $D_{2,6}$ be the Deninger cycle associated with $P_{2,6}$. The map $(x,y,t) \mapsto t$ endows $D_{2,6}$ with a fibration over the interval $[-2, -1]$.

**Proof.** From the equation $P_{2,6}(x,y,t) = 0$ we deduce that $f(t) \in [0, 9]$ and thus $t + 1/t \in [-5/2, 2]$. Together with $|t| > 1$ this implies that $t$ is real and $t \in [-2, -1]$. □

This shows that $D_{2,6}$ is fibered over the modular symbol $\{1/2, 2/3\}$. Proceeding as in the previous cases, we find that $D_{2,6}$ is homologous to $Y\{1/2, 2/3\}$.

The horizontal divisors of $x, y$ viewed as rational functions on $E_i$ can be obtained from (29) by replacing $(kA)$ with its pullback $(kA_2)$:

$$\text{div}(x) = (0) - (2A_2) - (3A_2) + (5A_2), \quad \text{div}(y) = (0) + (A_2) - (3A_2) - (4A_2).$$

As in the case of $E_1(6)$, the Eisenstein symbol on $E(6)$ corresponding to $\pi^{\ast}\{x,y\}$ is

$$\pi^{\ast}\{x,y\} = \pm 12\text{Eis}^1((0,1) + (0,2)).$$

Since $P_{2,6}^2 = 2$, the difference $m(P) - \log 2$ is the integral over $Y\{1/2, 2/3\}$ of the symbol

$$\eta = \pm 36\text{Eis}^{0,1}((3,0) + (3,1) - (3,2) - (3,3), (0,1) + (0,2)).$$

Notice that $\{1/2, 2/3\} = \{g0, g\infty\}$ with $g = \left(\begin{smallmatrix} 2 \\ 3 \\ 1 \\ 2 \end{smallmatrix}\right) \in \text{SL}_2(\mathbb{Z})$. So this is also the integral over $X\{0, \infty\}$ of

$$\eta' = 3g^{\ast}\eta - 2(g\sigma)^{\ast}\eta.$$

At this point we conclude as before with the main theorem of [12],

$$m(P) - \log(2) = -\Lambda\left(\frac{1}{4}E - \frac{3}{2}f_{12}, 0\right),$$

where $f_{12} = q - 3q^3 + 2q^7 + O(q^9)$ is the unique newform in $S_3(\Gamma_1(12))$ with rational Fourier coefficients and $E = E_3^{1,\chi_3} + 7E_3^{1,\chi_3^2} - 8E_3^{1,\chi_3^4}$. It remains to find $\Lambda(E, 0)$, which, by (28), equals

$$2L(\chi_3, -2)\zeta(0) \lim_{s \to 0} \Gamma(s)(1 + 7 \cdot 2^{-s} - 8 \cdot 4^{-s}) = 2\log(2).$$

We summarize as follows.

**Theorem 9.7.** We have

$$m(P_{2,6}) = \frac{3}{2} \Lambda(f_{12}, 0) + \frac{\log(2)}{2}.$$

9.5. **The surface $E(4)$**. For the universal elliptic curve $E(4)$ attached to the group $\Gamma(4)$, we proceed slightly differently from the $\Gamma_1(8)$ case: we avoid the use of Stokes’s theorem and the consideration of residues at the cusps, using instead a distribution relation satisfied by Eisenstein symbols.

According to the Rouse–Zureick-Brown tables [22], a model of $E(4)$ over $\mathbb{Q}(i)$ is given by

$$E(4) : y^2 = x^3 + Ax + B,$$

with $A = -27t^8 - 378t^4 - 27$ and $B = 54t^{12} - 1782t^8 - 1782t^4 + 54$. Here $t$ is a generator of the function field of $Y(4)$; more precisely, we have $\mathbb{Q}(Y(4)) = \mathbb{Q}(i)(t)$.
Since the singular fibers of $E(4)$ are $t = 0, \pm 1, \pm i, \infty$, it follows that $t$ is a modular unit. In the following lemma we express $t$ as a quotient of Siegel units.

**Lemma 9.9.** We have $t = ig_1^2/g_1^2$. \hfill $\Box$

Proof. The torsion subgroup of $E(4)$ over $\mathbb{Q}(i)(t)$ is isomorphic to $\mathbb{Z}/4\mathbb{Z} \times \mathbb{Z}/4\mathbb{Z}$, generated by the two points of order 4,

$$P_1 = (3t^4 + 18it^3 - 18t^2 - 18it + 3, -54it^5 + 108t^4 - 108it^3 - 54it),$$

$$P_2 = (-15t^4 + 3, -54it^6 + 54it^2).$$

From these expressions we find that

$$t = \frac{x(P_1 + P_2) - x(2P_1 + 2P_2)}{x(2P_1 + 2P_2) - x(2P_1 + P_2)}.$$\hfill $\Box$

In particular, $t$ is a Weierstrass unit and we may express it as a quotient of Siegel units. We parametrize $E(4)$ in such a way that $P_1, P_2$ correspond to $z_1 = 1/4$, $z_2 = \tau/4$, respectively (this identification is compatible with the Weil pairing). This gives

$$t(\tau) = \frac{\varphi_\tau(\tau/4 + 1/4) - \varphi_\tau(\tau/2 + 1/2)}{\varphi_\tau(\tau/2 + 1/2) - \varphi_\tau(\tau/4 + 1/2)} = i\frac{g_1.3g_{1,2}^2}{g_1.1g_{1,0}g_{3,0}} = i\frac{g_{2,2}}{g_{3,3}}.$$\hfill $\Box$

Proceeding as in the case of $E_1(8)$, we deduce the lemma.

Since we know how to evaluate Siegel units at cusps, we get the following result.

**Lemma 9.9.** We have $t(\infty) = i$ and $t(1/2) = t(-1/2) = -i$.

Using Magma, we find two functions $X, Y$ on $E(4)$ such that $(X, Y) \in H^2_\text{M}(E(4), \mathbb{Q}(2))$. Their divisors are given by

$$\text{div}(X) = -2(2P_2) + 2(2P_1 + 2P_2), \quad \text{div}(Y) = -2(P_1) + 2(3P_1),$$

and they satisfy the relation

$$P(X, Y, t) = (X + \frac{1}{X} - 2)(Y + \frac{1}{Y} + 2) + 2\frac{(t - i)^4}{(t^3 - t)^4} = 0.$$\hfill $\Box$

Let $D \subset V(P)$ be the Deninger cycle associated with $P$ with respect to the variable $t$. By Jensen’s formula we have

$$(30) \quad m(P) - m(P^*) = \frac{1}{(2\pi i)^2} \int_D \log |t| \cdot \frac{dX}{X} \wedge \frac{dY}{Y} = \frac{1}{(2\pi i)^2} \int_D \log |t| \cdot \pi_2(\frac{dX}{X} \wedge \frac{dY}{Y}).$$

We now want to relate $D$ to a Shokurov cycle on the connected component of $E(4)(\mathbb{C})$ defined as the image of the map $(\tau, z) \mapsto (\tau, z, \sigma)$.

**Lemma 9.10.** Let $C_1$ (resp., $C_2$) be the circle with center 1 (resp., -1) passing through $i$ in the complex plane. Then $t(D)$ is the union of the two arcs $C_1 \cap \{|t| > 1\}$ and $C_2 \cap \{|t| > 1\}$.

Proof. Let $(X, Y, t) \in D$. Since $|X| = |Y| = 1$, we have $2i(t - i)^4/(t^3 - t) \in \mathbb{R}$. Writing $t = u + iv$, we find the equation

$$2u(u^2 + v^2 + 2u - 1)(u^2 + v^2 - 2u - 1)(u^2 + v^2 - 1) = 0.$$\hfill $\Box$

We have $X + 1/X - 2 \in [-4, 0]$ and $Y + 1/Y + 2 \in [0, 4]$, and thus $2i(t - i)^4/(t^3 - t) \in [0, 16]$. The equation $u = 0$ leads to $-2(v - 1)^4/(v^3 + v) \in [0, 16]$, which is impossible for $|v| > 1$. Therefore $t(D)$ is contained in the union of the two arcs.
Conversely, let \( t \in C_1 \cup C_2 \), with \( |t| > 1 \). Since \( D \) is invariant under \((X,Y,t) \mapsto (X,Y,-t)\), it suffices to treat the case \( t \in C_1 \). So let us write \( t = 1 + \sqrt{2}\mathrm{e}^{i \theta} \) with \( \theta \in (-3\pi/4, 3\pi/4) \). We find that
\[
\begin{align*}
2i\frac{(t - i)^4}{t^3 - t} &= \frac{2i(t - i)^4(t^3 - \bar{t})}{|t^3 - \bar{t}|^2} \\
&= \frac{416 + 384\sqrt{2}\cos \theta - 224\sqrt{2}\sin \theta + 128\cos(2\theta) - 224\sin(2\theta) - 32\sqrt{2}\sin(3\theta)}{52 + 48\sqrt{2}\cos \theta + 16\cos(2\theta)}.
\end{align*}
\]
An explicit computation reveals that this function takes values in \([0,16]\), hence there exist \( X,Y \in S^1 \) such that \( P(X,Y,t) = 0 \).

**Lemma 9.11.** The map \( \tau \mapsto t(\tau) \) is a diffeomorphism from the modular symbols \( \{-1/2, \infty\} \) and \( \{1/2, \infty\} \) to \( C_1 \cap \{|t| > 1\} \) and \( C_2 \cap \{|t| > 1\} \), respectively.

*Proof.* We want to show that for \( \tau \in \{1/2, \infty\} \), the point \( t(\tau) \) lies on \( C_2 \), that is, \( |t(\tau)|^2 = 2 \). Using \( t(-\tau) = -t(\tau) \), we can then conclude that \( t(\{-1/2, \infty\}) \) lies on \( C_1 \).

The functions \( t + 1 \) and \( t - 1 \) are modular units, since \( t(1) = -1 \) and \( t(3) = 1 \). Their expression in terms of Siegel units is given by
\[
t + 1 = g_0, g_1, g_2, g_3, g_4, g_5, g_6, g_7, g_8, g_9, g_{10}, g_{11}, g_{12}, g_{13}, g_{14}, g_{15}, g_{16},
\]
\[
t - 1 = -2g_0, g_1, g_2, g_3, g_4, g_5, g_6, g_7, g_8, g_9, g_{10}, g_{11}, g_{12}, g_{13}, g_{14}, g_{15}, g_{16}.
\]
From Proposition 6.1 we see that \( \left( \begin{smallmatrix} 1 & -1 \\ 0 & 1 \end{smallmatrix} \right)^* (t - 1) = -2(t + 1)^{-1} \). So for \( v \in \mathbb{R} \)
\[
t(1/2 + iv) + 1 = -(t(-1/2 + iv) - 1) = -\left( \begin{smallmatrix} 1 & -1 \\ 0 & 1 \end{smallmatrix} \right)^* (t - 1)(1/2 + iv) = \frac{2}{t(1/2 + iv) + 1},
\]
which shows that \( |t(1/2 + iv) + 1|^2 = 2 \).

It remains to prove that \( |t(1/2 + iv)| > 1 \). For \( \tau = 1/2 + iv \) we have
\[
|t(\tau)|^2 = t(\tau)\bar{t}(\bar{\tau}) = -t(\tau)t(-\bar{\tau}) = -t(\tau)t(\tau - 1) = \frac{t(\tau)(1 - t(\tau))}{1 + t(\tau)}.
\]
So \( |t(\tau)| = 1 \) implies that \( t(\tau) - t(\tau)^2 = 1 + t(\tau) \), so \( t(\tau) = \pm i \). But these values correspond to cusps, so we get a contradiction. To conclude, it suffices to show that \( |t(1/2 + iv)| > 1 \) for one particular value of \( v \), which we can check numerically.

To show that the map \( t : \{1/2, \infty\} \to C_2 \cap \{|t| > 1\} \) is a diffeomorphism, it remains to show that it is injective. Since \( t \) is a Hauptmodul for \( \Gamma(4) \backslash \mathcal{H} \), it suffices to show that the projection from \( \{1/2, \infty\} \) to \( \Gamma(4) \backslash \mathcal{H} \) is injective. In fact even \( \{1/2, \infty\} \to \Gamma_1(4) \backslash \mathcal{H} \) is injective, which can be shown with [28, Lemma 3.3.4], as in Lemma 8.2.

By the previous lemmas we see that \( D = D_1 \cup D_2 \), where \( D_1 \) (resp., \( D_2 \)) is fibered over \( \{-1/2, \infty\} \) (resp., \( \{1/2, \infty\} \)). Moreover, a numerical computation reveals that \( D_2 \) is fiberwise homologous to the Shokurov cycle \( \gamma = (2X - Y)\{1/2, \infty\} \). Let us consider the complex conjugation \( c_0 : (\tau, z, \sigma) \mapsto (-\bar{\tau}, \bar{z}, \sigma) \) on \( E(4)(\mathbb{C}) \). This involution corresponds to the map \((X,Y,t) \mapsto (\bar{X}, 1/\bar{Y}, -t)\) on \( V(P) \). It thus exchanges \( D_1 \) and \( D_2 \) and reverses the orientations. It follows that \( D \) is fiberwise homologous to \( \gamma - c_0(\gamma) \) as an oriented cycle.

Let us now turn to the integrand of (30). Using similar arguments to those in Lemma 8.1 we have
\[
m(P) - m(P^*) = \pm \frac{1}{(2\pi i)^2} \frac{256}{3} \int_D \eta,
\]
with
\[ \eta = (\text{Eis}_D^0(1, 2) - \text{Eis}_D^0(1, 0)) \cdot \pi_2(\text{Eis}_{\text{hol}}^1(2, 1)). \]

Note that the differential form \( \text{darg} t \) does not vanish on \( D \), so we cannot write the Mahler measure as an integral of a closed differential form as in Lemma 8.1. Since \( \eta \) is holomorphic with respect to \( z \) and since \( c_0^* \eta = -\eta \), we have
\[ \int_D \eta = \int_{\gamma} \eta - \int_{\text{co}(\gamma)} \eta = 2 \int_{\gamma} \eta. \]

Note that \( \gamma = (2X - Y)\{1/2, \infty\} \) is a sum of two Manin symbols, but since \( \eta \) is not closed, we cannot apply Stokes’s theorem as in §8. Instead we use the following degeneracy map from \( E(8) \) to \( E(4) \):
\[ \lambda : (\mathbb{Z}^2 \times \Gamma(8))(\mathcal{H} \times \mathbb{C}) \to (\mathbb{Z}^2 \times \Gamma(4))(\mathcal{H} \times \mathbb{C}), \]
\[ (\tau, z) \mapsto \left( \frac{\tau + 1}{2}, z \right). \]

We have \( \gamma = \lambda \ast X \{0, \infty\} \) so that
\[ \int_{\gamma} \eta = \int_{\lambda \ast X \{0, \infty\}} \eta = \int_{X \{0, \infty\}} \lambda^* \eta. \]

Using the Fourier expansion of Eisenstein symbols [12 §8], we compute
\[ \lambda^* \text{Eis}_{\mathcal{B}}^{0,4}(a, b) = 2 \sum_{a' \equiv a \pmod{4}} \text{Eis}_{\mathcal{D}}^{0,8}(a', a' + 2b), \]
\[ \lambda^* \text{Eis}_{\text{hol}}^{1,4}(a, b) = 4 \sum_{a' \equiv a \pmod{4}} \text{Eis}_{\text{hol}}^{1,8}(a', a' + 2b), \]
where \( \text{Eis}^{k, N} \) denotes the Eisenstein symbol of weight \( k \) and level \( N \). It follows that
\[ \lambda^* \eta = 8(\text{Eis}_{\mathcal{D}}^{0,8}(1, 5) + \text{Eis}_{\mathcal{D}}^{0,8}(5, 1) - \text{Eis}_{\mathcal{D}}^{0,8}(1, 1) \]
\[ - \text{Eis}_{\mathcal{D}}^{0,8}(5, 5)) \cdot \pi_2(\text{Eis}_{\text{hol}}^{1,8}(2, 4) + \text{Eis}_{\text{hol}}^{1,8}(6, 0)). \]

By Proposition 7.3(2) the integral of \( \lambda^* \eta \) is convergent. Applying the formulas [12 top of p. 1149], [12 (36)], we obtain \( m(P) - m(P^*) = \pm \Lambda(F(2\tau), 0) \), with
\[ F = 4f_{16} - 2E_3^{1,4} + 2E_3^{1,4,2}. \]

Since \( m(P^*) = \log 2 = \Lambda(2E_3^{1,4} - 2E_3^{1,4,2}, 0) \), we finally get \( m(P) = 4\Lambda(f_{16}, 0) \). The change of variables \( (X, Y, t) \to (-X, Y, -it) \) gives the last identity of Theorem 1.1.

Acknowledgments

The first author thanks Odile Lecacheux for her suggestion to give a modular proof of Bertin’s results, and for communicating her method to obtain a modular parametrization. The authors also thank Marie-José Bertin for the interesting discussions and encouragement throughout this project, and Wadim Zudilin for useful feedback on our results. The second author also thanks Bartosz Naskrecki and Chris Wüthrich for the helpful conversations about elliptic surfaces. Finally, we thank the anonymous referees for their careful reading and comments leading to an improvement of the article.
