ON TRANSCENDENTAL NUMBERS*

BY

AUBREY J. KEMPNER

In 1851, Liouville† gave the following theorem (the proof of which is very simple):

Let \( f(z) = 0 \) be an equation of degree \( n \geq 2 \) with real integral coefficients and irreducible in the domain \( R(1) \), \( z \) a real root of this equation, and \( p/q \) any real rational number. Then a positive number \( A \) can be found, which is independent of \( n \), such that for all \( p/q \),

\[
\left| z - \frac{p}{q} \right| > \frac{1}{Aq^n}.
\]

By applying his theorem to numbers of the form \( \sum_{v=1}^{\infty} (\alpha_v/l^v) \), \( l \) a positive integer \( \geq 2 \), \( \alpha_v \) any integer whose absolute value is limited, Liouville showed that all such numbers are transcendental.

By choosing \( l = 10 \), a rule is obtained for representing in decimal-fraction form the numbers contained in a certain non-enumerable set of transcendental numbers.‡

From Liouville’s method of proof it follows that all numbers \( \sum_{v=0}^{\infty} (\alpha_v/l^{\gamma_v}) \), when only \( \gamma_v \) increases “sufficiently rapidly,” are transcendental.

E. Maillet§ proves in his book the transcendency of the members of certain sets of numbers, the simplest of which are represented by series of the type

\[
\sum_{n=0}^{\infty} (a_n + b^m n^m) \cdot x^n
\]

for all rational and even for all algebraic \( x \), and G. Faber|| uses a generalization of Liouville’s theorem and treats a more general type of series which may

by this method be shown to yield transcendental numbers, namely all series of the form

$$f(x) = \sum_{n=0}^{\infty} \frac{h_n \cdot x^n}{(p_1 \cdot p_2 \cdots p_n)^{q_1 \cdot q_2 \cdots q_n}}.$$  

where the $h_n, p_n, q_n$ are integers, $h_n$ finite (or growing infinite with $n$ in some particular fashion),

$$p_n > 1, \quad \lim_{n \to \infty} q_n = \infty;$$

and he shows that $f(x)$ is a transcendental number for all algebraic $x$. These seem to be about the only advances along this line.* Series of the type $\sum_{n=0}^{\infty} \left( \alpha_n/a^{b_n} \right)$ cannot be treated by these methods.

The object of the present paper is to prove the following

**Theorem.** Let $a$ be an integer greater than 1, $p/q$ a rational fraction, $p \geq 0$, $q > 0$; $\alpha_n$, $(n = 0, 1, 2, \cdots)$, any positive or negative integer smaller in absolute value than a fixed arbitrary number $M$, but only a finite number of the $\alpha_n$ equal to 0; then $\sum_{n=0}^{\infty} \left( \alpha_n/a^{b_n} \right) \cdot (p/q)^n$ is always a transcendental number.

We shall prove the theorem in the form just stated. However, the proof still holds, with only slight modifications, for either or both of the following extensions:

1. The exponent $2^n$ may be replaced everywhere by $b^n$, $b$ any fixed positive integer greater than 2.

2. $\alpha_n$ need not be limited; for example, the number is transcendental when $|\alpha_n| < R^n$, $R$ an arbitrary fixed number; or $\alpha_n$ may be a rational number $\delta/\epsilon$, $|\delta| < R^n$, $\epsilon < R^n$, but always with the restriction that only a finite number of the $\alpha_n$ equal to 0.

**Proof.** All letters to be used will denote real numbers and all are integers except $z$ and $c_3$. The symbol $r^{(a)}$ means $r^{(a_1)}, r^{(a_2)}, \ldots$, means $r^{(a_3)}$, etc.

Max. $(a_1, a_2, a_3, \cdots, a_r)$ denotes the largest of the positive values $a_1, a_2, a_3, \cdots, a_r$.

Let $z = \sum_{n=0}^{\infty} \left( \alpha_n/a^{b_n} \right) \cdot (p/q)^n$, with the restrictions on the $\alpha_n, a, p$, and $q$ mentioned in the theorem.

If $z$ is not a transcendental number, there must exist a certain equation

$$f(z) = \sum_{\mu=0}^{k} A_\mu z^\mu = 0,$$

where $k$ is a fixed positive integer and the $A_\mu$ are integers, $A_k \neq 0$. Let $N$ be a positive integer, such that $N > |A_\mu|$, $(\mu = 0, 1, \cdots, k)$. We shall

---

* E. Borel, *Leçons sur la théorie de la croissance, recueillies et rédigées par A. Denjoy*, Paris (1910), Chapter V, and Axel Thue, *Journal für Mathematik*, vol. 135 (1909), p. 284, particularly the latter, have generalized Liouville's theorem in important respects, but these generalizations have so far not had any influence on the investigation of transcendental numbers.
substitute \( z = \sum_{n=0}^{\infty} (\alpha_n/a^n) \cdot (p/q)^n \) in \( f(z) \) and shall show that \( f(z) \neq 0 \) for any given \( f(z) \).

Once chosen, all of the following numbers are to be considered constant: \( \alpha_n \) \((n = 0, 1, \cdots)\); \( a; p; q; k; A_\mu \) \((\mu = 0, 1, 2, \cdots, k)\); \( M; N \).

Since \( \sum_{n=0}^{\infty} (\alpha_n/a^n) \cdot x^n \) is a power-series, convergent for all values of \( x \), we may substitute \( z \) in \( f(z) \) and rearrange terms as we like. After substituting, we shall arrange the terms according to increasing denominators, without canceling anywhere, and collect terms with equal denominators.

The denominators are formed by taking the product of \( k \) or fewer factors of the form \( a^{2^n} \cdot q^n \), repetition admitted.

We prove first the following statement:

When at the same time \( n > k \) and \( n > n_1 \), where \( n_1 \) is a certain positive integer which will be characterized in the proof, then the three numbers

\[
\begin{align*}
\gamma_1 &= a^{2^{n-k+1}+2^{n-k}+\cdots+2^{n-1}+2^{n-2}+\cdots+2+k+1+n-k+1}, \\
\gamma_2 &= a^{2^{n-k+1}+2^{n-k}+\cdots+2^{n-1}+2^{n-k}+\cdots+2+k+n-k+1+n-k}, \\
\gamma_3 &= a^{2^n} \cdot q^n
\end{align*}
\]

satisfy the two conditions:

(1) \( \gamma_1 < \gamma_2 < \gamma_3 \),

(2) \( \gamma_1, \gamma_2, \gamma_3 \)

are three consecutive denominators of our fractions in \( \sum_{\mu=0}^{k} A_\mu a^n \).

It is clear that all denominators containing any factor \( a^{2^\nu}, \nu > n \), are larger than \( \gamma_3 \), and of all denominators containing the factor \( a^{2^n}, \gamma_3 \) is the smallest. Consequently all denominators smaller than \( \gamma_3 \) contain only factors \( a^{2^n} \cdot q^n \), \((\nu = 0, 1, \cdots, n - 1)\). Of all denominators smaller than \( \gamma_3 \) containing not more than \( k \) of these factors, \((n > k)\), it is obvious that there is none between \( \gamma_2 \) and \( \gamma_1 \) and none between \( \gamma_3 \) and \( \gamma_2 \). It remains however to be shown that \( \gamma_2 < \gamma_3 \), in spite of the higher powers of \( q \) involved in \( \gamma_2 \), that is:

\[
a^{2^{n-k+1}+2^{n-k}+\cdots+2^{n-k}+\cdots+2+k+n-k+1+n-k} < a^{2^n} \cdot q^n
\]

for all \( n \) from a certain value on. We have

\[
\frac{1}{q^{(n-1)+(n-2)+\cdots+(n-k)}} < a^{2^n} < a^{2^n} \cdot q^n
\]

which is a fortiori satisfied when

\[
q^{n^{n/2}} = (q^{\frac{1}{2}})^n < a^{2^n} = (a^{2^n})^{2^n}
\]

this is true from a certain integer \( n = n_1 \) on. Thus our statement is proved, and we shall henceforth take \( n \) greater than \( \text{Max} (k, n_1) \).
To prove that \( f(z) \neq 0 \), we shall show that \( f(z) \) may be written in the form

\[
f(z) = \frac{c_1}{\gamma_1} + \frac{c_2}{\gamma_2} + c_3,
\]
satisfying the following conditions:

(a) \( c_1, c_2 \) are integers, \( c_1 \equiv 0, c_2 \neq 0 \); \( c_3 \) a real number \( \not\equiv 0 \); \( \gamma_1, \gamma_2 \) numbers of the type defined above, so that \( \gamma_2 \) is a multiple of \( \gamma_1 \); \( \gamma_2 = l \cdot \gamma_1, l > 1 \).

(b) \( \left| \frac{c_3}{\gamma_2} \right| < \frac{1}{\gamma_1} \).

(c) \( \left| \frac{c_3}{\gamma_2} \right| < \frac{1}{\gamma_2} \).

We must admit four possible cases:

If \( c_1 = 0, c_3 = 0 \): \( f(z) \neq 0 \) because \( c_2 \neq 0 \).

If \( c_1 = 0, c_3 \neq 0 \): \( f(z) = \frac{c_2}{\gamma_2} + c_3 \neq 0 \) from (a) and (c), without using (b).

If \( c_1 \neq 0, c_3 = 0 \): \( f(z) = \frac{c_1}{\gamma_1} + \frac{c_2}{\gamma_2} \neq 0 \) from (a) and (b), without using (c).

If \( c_1 \neq 0, c_3 \neq 0 \): \( \frac{c_1}{\gamma_1} - \frac{c_2}{\gamma_2} > 0 \), therefore

\[
\left| \frac{c_1}{\gamma_1} \right| - \left| \frac{c_2}{\gamma_2} \right| \geq \frac{1}{\gamma_2} > |c_3|,
\]

and hence

\[
f(z) = \frac{c_1}{\gamma_1} + \frac{c_2}{\gamma_2} + c_3 \neq 0.
\]

Always assuming that no cancellations have been performed, either in

\[
\sum_{n=0}^{\infty} \left( \frac{\alpha_n}{z^n} \right) \cdot \left( \frac{p}{q} \right)^n \quad \text{or in} \quad \sum_{n=0}^{\infty} A_n z^n,
\]

our \( c_2/\gamma_2 \) shall consist of all terms which have exactly the denominator

\[
\gamma_2 = a^{n-1+2n-2+\cdots+2n-k} \cdot q^{(n-1)+(n-2)+\cdots+(n-k)},
\]

\( n \) being properly chosen. Evidently \( c_2/\gamma_2 \) arises entirely from the term \( A_k z^k \) of \( f(z) \), and we obtain

\[
\frac{c_2}{\gamma_2} = \frac{A_k \cdot \alpha_{n-1} \cdot \alpha_{n-2} \cdots \alpha_{n-k} \cdot p^{(n-1)+(n-2)+\cdots+(n-k)}}{a^{n-1+2n-2+\cdots+2n-k} \cdot q^{(n-1)+(n-2)+\cdots+(n-k)}} \cdot \frac{k!}{1 \cdot 1 \cdots 1},
\]

\[
\left| \frac{c_2}{\gamma_2} \right| \leq \frac{k! N \cdot M^k \cdot |p|^{(n-1)+(n-2)+\cdots+(n-k)}}{a^{n-1+2n-2+\cdots+2n-k} \cdot q^{(n-1)+(n-2)+\cdots+(n-k)}}
\]

and \( c_2 \neq 0 \), provided \( n > n_2 \), where \( n_2 \) is so large that \( \alpha_{n-k} \) and all following coefficients are different from zero.
Our \( c_1/\gamma_1 \) shall comprise all terms with denominators smaller than \( \gamma_2 \). If \( c_1 = 0 \), \( c_1/\gamma_1 \) is not needed. If \( c_1 \neq 0 \), then

\[
\gamma_1 = a^{2^{i_1}+2^{i_2}+\cdots+2^{i_k}+2^{k+1}} \cdot q^{(n-1)+(n-2)+\cdots+(n-k)+1+(n-k-1)}
\]

is common denominator of all fractions under consideration, which can therefore be added together, giving \( c_1/\gamma_1 \).

To prove \( |c_2|/\gamma_2 < 1/\gamma_1 \), we show that, from a certain \( n = n_3 \) on,

\[
\frac{k! \cdot N \cdot M^k \cdot |p|^{(n-1)+(n-2)+\cdots+(n-k)}}{a^{2^{i_1}+2^{i_2}+\cdots+2^{i_k}+2^{k+1}} \cdot q^{(n-1)+(n-2)+\cdots+(n-k)+1+(n-k-1)}} < \frac{1}{a^{2^{i_1}+2^{i_2}+\cdots+2^{i_k}+2^{k+1}} \cdot q^{(n-1)+(n-2)+\cdots+(n-k)+1+(n-k-1)}}
\]

We assume \( n > \text{Max}(k, n_1, n_2) \). Our inequality reduces to

\[
\frac{k! \cdot N \cdot M^k \cdot |p|^{(n-1)+(n-2)+\cdots+(n-k)}}{q} < a^{2^{i_1}+1},
\]

which is a fortiori satisfied if

\[
C_1 \cdot |p|^{n/2} < a^{2^{i_1}+1},
\]

where

\[
C_1 = \frac{k! \cdot N \cdot M^k}{q}
\]

is independent of \( n \);

\[
C_1 \cdot |p|^n < (a^{2^{i_1}+1})^2,
\]

which is true from a certain \( n_3 \) on. We assume \( n > \text{Max}(k, n_1, n_2, n_3) \). This proves (b).

Our \( c_3 \) shall consist of all terms with denominators greater than \( \gamma_2 \), that is, of all terms of \( f(z) \) not accounted for by \( c_1/\gamma_1 + c_2/\gamma_2 \). Hence \( c_3 \) is built up of fractions of the form

\[
\frac{A_\mu \cdot \alpha_{\tau_1} \cdot \alpha_{\tau_2} \cdots \alpha_{\tau_\rho} \cdot p^{\tau_1+\tau_2+\cdots+\tau_\rho}}{a^{2^{\tau_1}+2^{\tau_2}+\cdots+2^{\tau_\rho}} \cdot q^{2^{\tau_1}+\tau_2+\cdots+\tau_\rho}},
\]

where \( \rho \leq k \), and \( \tau_1, \tau_2, \ldots, \tau_\rho \) are numbers of the sequence \( 0, 1, 2, \ldots \) not necessarily different from each other.

These denominators are all of the form \( a^{\nu_1} \cdot q^{\nu_2} \), where the exponents of \( a \) are formed by taking the sum of \( k \) or less numbers of the infinite sequence \( 2^n \), \( (\nu = 0, 1, 2, \ldots) \), repetition permitted, with the restriction that at least one of the \( k \) or fewer numbers \( 2^n \) shall be greater than or equal to \( 2^n \), where \( n > \text{Max}(k, n_1, n_2, n_3) \). There are, as is easily seen, less than \((n + 2)^k\) exponents that can be so formed from the first \( n + 1 \) numbers \( 2^0, 2^1, \ldots, 2^n \), counting exponents separately even when they differ only in the order of their
summands $2^{r_1}, 2^{r_2}, \cdots, 2^{r_p}$. In the same way it is seen that there are less than $(n + 3)^k$ exponents formed by taking only numbers of the set $2^0, 2^1, \cdots, 2^{n+1}$; less than $(n + l + 2)^k$ by taking only numbers of the set $2^0, 2^1, \cdots, 2^{n+1}$ for $l = 1, 2, 3, \cdots$. The denominators $a^{q^k}$ all contain also factors $q^k$. Hence there are certainly less than $(n + 2)^k$ fractions with denominators smaller than $a^m$, less than $(n + 3)^k$ fractions with denominators $d$, where $a^m \leq d < a^{m+1}$, because there are altogether less than $(n + 3)^k$ fractions with denominators less than or equal to $a^{m+1}$, and less than $(n + l + 2)^k$ fractions with denominators $d$, where $a^{m+1} \leq d < a^{m+2}$. I increase (or at least do not decrease) the absolute value of all fractions by replacing $q^k$ by 1.

Those numerators belonging to denominators $d$, $a^m \leq d < a^{m+1}$, have all of their $\tau_1, \tau_2, \cdots, \tau_p$ not larger than $n$, those belonging to denominators $d$, $a^{m+1} \leq d < a^{m+2}$, have all of their $\tau \leq n + 1$, and those fractions with denominators $d$, $a^{m+2} \leq d < a^{m+3}$, have all $\tau \leq n + l$.

Altogether we find for $c_3$:

$$|c_3| < N \cdot M^k \cdot \left[ \frac{(n + 2)^k \cdot |p|^{kn}}{a^m} + \frac{(n + 3)^k \cdot |p|^{(n+1)k}}{a^{m+1}} + \cdots \right] + \frac{(n + l + 2)^k \cdot |p|^{(n+1)k}}{a^{m+2}} + \cdots].$$

The convergence of this expression is obvious. Besides taking $n$ greater than Max. $(k, n_1, n_2, n_3)$ we now take $n$ so large that the sum in brackets is smaller than

$$2(n + 2)^k \cdot |p|^{kn}.$$

This is certainly true when the ratio of two consecutive terms is always smaller than $\frac{1}{2}$, and happens, for example, when $n > \log_2 (k \cdot \log_2 |4p|)$, as is easily verified. Let $n_4$ be an integer satisfying this relation, and take $n$ greater than Max. $(k, n_1, n_2, n_3, n_4)$. Substituting, we have

$$|c_3| < \frac{2N \cdot M^k \cdot (n + 2)^k \cdot |p|^{kn}}{a^m},$$

and we shall show that the expression on the right is, for sufficiently large values of $n$, less than

$$\frac{1}{a^{m+1} + a^{m-1} + \cdots + a^{m-k}},$$

thus establishing the inequality $|c_3| < 1/\gamma_2$ and proving our theorem.

Our inequality for $n$ reduces to

$$2N \cdot M^k \cdot (n + 2)^k \cdot |p|^{kn} \cdot q^{(n-1)+(n-2)+\cdots+(n-k)} < a^{m-k},$$
which is a fortiori satisfied when

\[ C_2 \cdot (n + 2)^k \cdot |p^k|^n \cdot (q^k)^n < (a^{2^n})^n, \]

where \( C_2 = 2N \cdot M^k \) is independent of \( n \).

By making \( n \) sufficiently large we can satisfy the following three inequalities simultaneously:

\[ C_2 \cdot (n + 2)^k < |p^k|^n, \quad |p^{2k}|^n < (q^k)^n, \quad q^n < (a^{2^n})^n, \]

which, combined, prove our inequality for all \( n \) greater than a certain integer \( n_6 \).

By taking \( n \) greater than \( \text{Max.}(k, n_1, n_2, n_3, n_4, n_5, n_6) \) we meet all restrictions which have been successively imposed on \( n \) during the proof.

The condition that only a finite number of coefficients shall be zero (in order to ensure \( c_2 \neq 0 \)), I have not been able to remove.

By taking \( p/q = 1 \), we see that all numbers \( \sum_{n=0}^{\infty} \left( \frac{\alpha_n}{a^{2^n}} \right) \), \( \alpha_n \) an integer, \( |\alpha_n| \) limited, and from a certain point on \( |\alpha_n| \equiv 1 \) are transcendental.

As another special case we mention the function, \( \sum_{n=0}^{\infty} x^{2^n} \), introduced by Fredholm* to demonstrate the existence of analytical functions possessing certain peculiar properties on their natural boundaries. It follows from our theorem that this function has transcendental values for an infinite set of real rational values of the argument having the origin as a limiting point.

Urbana, Illinois
