CLASSIFICATIONS OF RECURSIVE FUNCTIONS
BY MEANS OF HIERARCHIES\(^{(1)}\)

BY

SOLOMON FEFERMAN

1. Introduction. The motivations for attempting to find a satisfactory classification of recursive functions by ordinals are rather well known; cf., for example [6, pp. 67–68]. Among other things, such a classification should give insight into how the nonconstructively defined class of arbitrary recursive functions can be successively approximated by classes of functions whose members can be constructively recognized to be everywhere defined and computable. It should also provide a framework for the (partial) characterization of the strength of various formalized theories, through the classification of the provably recursive functions of those theories. Finally, it might be hoped that such a classification would provide a new tool for obtaining results of purely mathematical interest about recursive functions.

It has been pointed out by Myhill [11] and independently by Routledge [13] that the most obvious attempt to define such a classification, namely in terms of recursions over previously constructed recursive well-orderings of the natural numbers, already gives all recursive functions by suitable choice of primitive recursive well-orderings of order type \(\omega\). This is quite naturally considered a “breakdown,” since none of the ends desired from such a classification are at all realized.

Another approach to the classification problem has been suggested by Kleene in [6]. This harks back to the idea that from any constructively generated class of recursive functions we are able to obtain new functions by diagonalization or, more generally, by enumeration. Transfinite iteration of this procedure leads to a hierarchy of recursive functions, most conveniently described with respect to some class of notations for recursive well-orderings. However, in order that such a classification not be trivialized at level \(\omega\), the set \(O\) of notations used should be restricted to those built up only by means of primitive recursive fundamental sequences [6, pp. 72–73]. We shall follow this restriction throughout this paper.

For functions \(\phi, \psi\) on natural numbers put (for the moment) \(\phi \ll \psi\) if \(\phi\) is primitive recursive in \(\psi\), but not conversely. Kleene’s hierarchy of functions \(p_d\) (denoted by \(h_d\) in [6]) has the property

\[
(1.1) \quad c <_o d \rightarrow p_c \ll p_d.
\]

Received by the editors July 21, 1961.
Another hierarchy of recursive functions $\rho_d$ which has this property when $\phi \ll \psi$ is interpreted to mean that $\phi$ is majorized by $\psi$, i.e., that $(Em)(n)(n > m \rightarrow \phi(n) < \psi(n))$, has been suggested to the author by Hartley Rogers, Jr. The possibility of obtaining such a hierarchy is easily seen from the fact that from any effectively enumerated class of recursive functions we can construct a recursive function which majorizes all elements of that class.

In this paper we consider a quite general class of hierarchies of recursive functions associated with given relations $\ll$, of which the above-mentioned are examples. Since, generally, uniqueness results fail for such hierarchies (cf. Axt [1], Kreisel [9], and 3.8 of this paper), it is natural to put questions of completeness in two ways. First, given $\kappa \leq \omega_1$, what can be said about the set of functions $\rho_d$ for $d \in O$, $|d| < \kappa$? Second, what can be said about the set of functions $\rho_d$ for $d \in P$, where $P$ is a path (set of notations well-ordered by $<_0$, and closed under predecessor) in $O$, $|P| = \kappa$? (We understand by $|d|$ the ordinal denoted by $d$, by $|P|$ the order type of $P$ under $<_0$, and by $\omega_1$ the least ordinal not denoted by any $d \in O$.)

The answers we obtain here to these questions are (under suitable conditions governing the "rate of growth" of the functions $\rho_d$) the following:

1.2. For any recursive function $\phi$ we can find $d \in O$ with $|d| = \omega^3$ and $\phi \ll \rho_d$.

1.3. We can find paths $P \subseteq O$ such that $|P| = \omega^3$ and such that for any recursive $\phi$ there is a $d \in P$ with $\phi \ll \rho_d$. Moreover, given any ordinal $\kappa \leq \omega_1$ we can find such paths with $|P| = \kappa + \omega^3$ if $\kappa < \omega_1$, $|P| = \omega_1$ otherwise.

1.4. We can find incomplete paths $P$ through $O$, in the sense that $|P| = \omega_1$ and there exist recursive functions $\phi$ such that $\rho_d \ll \phi$ (hence $\phi$ not $\ll \rho_d$) for all $d \in P$.

The results (1.2), (1.3) answer Kleene’s question P 236 [6, p. 77] for his hierarchy. An immediate corollary to (1.2), is the nonuniqueness of that classification for all $|d| \geq \omega^2$, thus completing the answer given by Axt in [1] to the question P 238. We also answer the question P 237 in part by means of the following result, which complements a converse result by Axt in [1]. (The present result has been obtained in collaboration with W. W. Tait.)

1.5. All the functions $\rho_d$ of the Kleene sub-recursive hierarchy for which $|d| < \omega^3$ are ordinal recursive with respect to the "natural" well-ordering of the natural numbers in type $\omega^3$.

A related result which we obtain is the following.

1.6. All the functions $\rho_d$ of the majorizing hierarchy for which $|d| < \omega^3$ are primitive recursive.

These results (1.5), (1.6) reinforce an opinion, which might already be taken on the basis of (1.2), that such hierarchies do not, when used with all notations, provide a satisfactory classification of recursive functions. Again, the reason for this breakdown can be localized in the liberalty with which we have provided ourselves notations for well-orderings.
However, it turns out that these hierarchies can still be used to obtain some new information about recursive functions, thus providing something in one direction demanded from a suitable classification. This is the following (hierarchy-free) result:

(1.7) There exists a set Δ of recursive functions densely ordered by \( \ll \); hence for any denumerable ordinal \( \kappa \) there exists a sequence of recursive functions \( \phi_i \), \( i < \kappa \), such that \( i < i' \rightarrow \phi_i \ll \phi_{i'} \).

But here hierarchies are used in an unexpected way, namely through certain "nonstandard" extensions of them.

Some of the results described above and the methods used to obtain them are closely related to (and were suggested by) certain results concerning recursive progressions of theories. In particular, (1.2) is related to a completeness result for arithmetical sentences of the form \( (\exists x)(\exists y) \gamma(x, y) = 0 \), \( \gamma \) primitive recursive, in suitable progressions of theories, obtained by us in [2, Theorem 5.2]. (1.3) is related to [2, Theorem 5.14], but the proof here is simpler since there are no problems of arithmetization involved. (1.4) is closely related to the incompleteness result of our paper with Spector [3, cf., Theorems 2.5, 4.4]. Finally, the methods used to obtain (1.7) exploit certain ideas incipient in [3].

It is perhaps accidental that these metamathematical results preceded the corresponding purely function-theoretic results. However, we believe that further work on the classification problem should involve metamathematical notions in an essential way. For this problem is intertwined with the question as to how we can generate recursive well-orderings which we can, in some sense, constructively verify on the basis of previously constructed functions and orderings to be well-orderings. An important step along these lines has already been taken in the work of Kreisel [10] on the question of classifying the class of finitistically acceptable recursive functions.

2. Hierarchies of functions. All lower case italics range as variables over the set \( 0, 1, 2, \cdots \) of natural numbers. All lower case Greek letters (with minor exceptions) and certain italic capitals range as variables over the class of total functions (and, on occasion, also partial functions) of one or more arguments from the set of natural numbers into itself. We use the notation \( a(i) \) instead of the more usual \( (a)_i \); thus \( 0(i) = 0 \), and for \( a \neq 0 \) and \( p_0, \cdots, p_n \), \( \cdots \) the primes in increasing order, \( a = \prod_{i=0}^{n} p_i^{a(i)} \).

The primitive recursive predicate \( In^m(b) (m > 0) \) is taken as defined in [6, p. 70]. When it holds we say that \( b \) is an \( (n-) \) index for defining a function \( \phi \) of \( n = b(0) \) arguments from any function \( \theta \) of \( m \) arguments by adjoining instances of primitive recursive schemata to the true numerical equations for \( \theta \). We shall only need this notion for the case \( m = 1 \). The \( n \)-ary function defined in this case from a given unary function \( \theta \) by \( b \) is denoted by \( [b]_{\theta}^n \). If \( b \) is not an \( n \)-index we take \( [b]_{\theta}^n(x_1, \cdots, x_n) = 0 \). We set \( [b]_n = [b]_{\theta}^{2^n(0)} \). We shall write \( [b]_{\theta}^n \) or \( [b]_n \) when \( n = 1 \) and also, where there is no ambiguity, for other values of \( n \). Thus \( [b]([b]_{\theta}^n) \) for \( b = 0, 1, 2, \cdots \) provides an enumeration
of all functions of one argument which are primitive recursive (in \( \theta \)) [6, p. 71].

We write \( \phi \subseteq \theta \) if \( \phi = \{ b \} \), \( \phi \subseteq \theta \) if \( (Eb) \phi \subseteq \theta \), and \( \phi \sqcap \theta \) if \( \phi \subseteq \theta \) but \( \theta \nsubseteq \phi \). We use the notation \( \{ e \} \) for the partial recursive function with Gödel-number \( e \), \( \{ e \} (x) \simeq U(\mu y T_1(e, x, y)) \).

The following adaptation of the recursion theorem to primitive recursive functions, proved by Kleene in [6, p. 75], is of great usefulness. We add to it, in the second part of the statement, a corollary needed for simultaneous recursions.

**2.1. Lemma.** (i) Given any primitive recursive function \( \psi(z, x_1, \ldots, x_n) \) we can find an \( e \) such that \( \{ e \} = \lambda x_1 \cdots x_n \psi(e, x_1, \ldots, x_n) \).

(ii) Given any primitive recursive functions \( \psi_i(z_0, z_1, x_1, \ldots, x_n) \) \( (i = 0, 1) \) we can find \( e_0, e_1 \) with \( \{ e_i \} = \lambda x_1 \cdots x_n \psi_i(e_0, e_1, x_1, \ldots, x_n) \).

To prove (ii) from (i), first find primitive recursive \( \theta_0, \theta_1 \) such that for any \( y, x_1, \ldots, x_n \), \( \theta(y)(x_1, \ldots, x_n) = ([y](x_1, \ldots, x_n)) \). We then determine \( f \) by (i) so that \( \{ f \} = \lambda x_1 \cdots x_n \psi_0(\theta_0(x_1, \ldots, x_n), \ldots, \theta_1(x_1, \ldots, x_n)) \). We then take \( e_i = \theta_i(f) \). (2.1 (ii) can obviously be generalized to obtain \( e_i, i = 0, \ldots, m \).

Throughout the remainder of this paper \( O, <_O \), and allied notions will be restricted to the case of primitive recursive fundamental sequences. (The notations \( O_p \) or \( O^p \) are avoided for simplicity.) Much of the theory for these notions can be adapted from [8] as described in [6]. Briefly, we obtain first a transitive recursively enumerable relation \( < \) such that (when we take \( x <_O y \iff x < y \\lor x = y \))

\[
a < b \iff b = 2^a (a) \neq 0 \& a < b (a), \\
\lor b = 3 \cdot 5^b (a) \& (En)a \leq b (a) (n).
\]

Then \( O \) is the smallest set which contains 1 and which, whenever it contains \( c \), contains \( 2^c \), whenever it contains \( [d](n) \) for all \( n \), where \( (n) \{ [d](n) < [d](n+1) \} \), contains \( 3 \cdot 5^c \cdot 2 \). We put \( a < b \iff a, b \in O \& a < b \). We denote by \( C(b) \) the set of \( x < b \) and by \( C'(b) \) the set \( C(b) \cup \{ b \} \). We take \( [b] \) to be the order type of \( C(b) \) when \( b \in O \). \( \omega_i \) is the least ordinal not thus represented. Kleene has shown in [6, p. 75] that this is the same as the ordinal obtained when \( O \) is defined with respect to arbitrary recursive fundamental sequences.

We put \( 0_0 = 1, (n+1)_0 = 2^{n_0} \) a suitable definition of \( +_0 \) has been given by Kleene in [6, p. 75]. We want, more generally, the following.

**2.3. Lemma.** Given primitive recursive functions \( \psi_0, \psi_1, \psi_2 \) (of 1, 3, 3 arguments) we can construct primitive recursive functions \( \phi, \gamma \) with (for all \( a, d \))

(i) \( \phi(a, 1) = \psi_0(a) \),

(ii) \( \phi(a, 2^d) = \psi_1(a, d, \phi(a, d)) \) for \( d \neq 0 \),

(iii) \( \phi(a, 3 \cdot 5^d) = \psi_2(a, d, \gamma(a, d)) \) where \( \gamma(a, d)(n) = \phi(a, [d](n)) \) for all \( n \).
The proof is similar to that for $+_o$ in [6]. Briefly, we can find primitive recursive $\theta$ with $[\theta(z, a, d)](n) = [z](a, [d](n))$ for all $z, a, d, n$. By course-of-values recursion we obtain primitive recursive $\phi^*(z, a, d)$ satisfying $\phi^*(z, a, 1) = \psi_0(a)$, $\phi^*(z, a, 2^d) = \psi_1(a, d, \phi^*(z, a, d))$ for $d \neq 0$, $\phi^*(z, a, 3 \cdot 5^d) = \psi_2(a, d, \theta(z, a, d))$, and $\phi^*(z, a, b) = 0$ for all other $b$. We then choose $e$ by 2.1(i) so that $[e](a, d) = \phi^*(e, a, d)$, and take $\phi = [e]$ and $\gamma(a, d) = \theta(e, a, d)$.

We shall write $a \oplus b$ instead of $a +_o b$. This is a primitive recursive function of $a, b$, satisfying $a \oplus 1 = a$, $a \oplus 2^d = 2^\alpha d$ $(d \neq 0)$, and $a \oplus 3 \cdot 5^d = 3 \cdot 5^{\gamma(a, d)}$ where $\gamma$ is primitive recursive and $[\gamma(a, d)](n) = a \oplus [d](n)$. For any $a, b, n$, $(a \oplus b) \oplus n_0 = a \oplus (b \oplus n_0)$, but $\oplus$ is in general not associative.

Hierarchies of recursive functions corresponding to certain generation principles can be constructed as in [6, p. 74] by defining certain partial recursive functions $\sigma(z, a)$ such that for each $d \in O$, $\rho_2 = \lambda x \sigma(d, x)$ is a recursive function, and such that the $\rho_i$'s are related in the desired fashion for different $d$'s. Alternatively, it is possible to generate the Gödel-numbers $\rho_2$ of these functions. This is more convenient for us here, and the general possibility of doing this follows directly from 2.3, if we omit the parameter "a" there.

2.4. Corollary. Suppose $q_1$ is the Gödel number of a recursive function and that $\psi_1, \psi_2$ are primitive recursive functions such that:

(i) if $f$ is a Gödel-number of a recursive function, then so also is $\psi_1(f)$;

(ii) if for each $n$, $[e](n)$ is a Gödel-number of a recursive function then so also is $\psi_2(e)$.

Then we can find primitive recursive $\phi, \gamma$ such that $\phi(1) = q_1$, $\phi(2^d) = \psi_1(\phi(d))$ for $d \neq 0$, $\phi(3 \cdot 5^d) = \psi_2(\gamma(d))$ where for all $n$, $[\gamma(d)](n) = \phi([d](n))$. It follows from these conditions that for each $d \in O$, $\rho_2 = \lambda x \{\phi(d)(x)\}$ is a recursive function.

We apply this to the construction of two hierarchies. First we have a slight variant of the hierarchy introduced by Kleene in [6, pp. 73–74].

2.5. Lemma. We can find primitive recursive $\psi_1, \psi_2$ so that:

(i) if $f$ is a Gödel-number of a recursive function $\theta(a)$ then $\psi_1(f)$ is a Gödel-number of the function $\theta'(a) = [a(0)]^*(a(1))$;

(ii) if for each $n$, $[e](n)$ is a Gödel-number of a recursive function $\theta_n(a)$ then $\psi_2(e)$ is a Gödel-number of the recursive function $\theta(a) = \theta_{n(0)}(a(1)) = \{[e](a(0))\}(a(1))$.

We shall refer to the resulting $\rho_2$'s associated by 2.4 with these $\psi_1, \psi_2$ and a Gödel-number $q_1$ of the constant function $\lambda x(0)$ as constituting the Kleene sub-recursive hierarchy. These have the property [6, p. 73] that if $c <_0 d$ then $\rho_c \subseteq \rho_d$; this is generalized in 5.3 below. Further properties needed for the results of this paper will be established in the next section.

As a second example, we construct a class of majorizing hierarchies each of which is associated with a given recursive function $\chi(a, b)$. Suppose given a Gödel number of $\chi$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
2.6. Lemma. We can find primitive recursive functions $\psi_1, \psi_2$ so that:

(i) if $f$ is a Gödel-number of a recursive function $\theta(a)$ then $\psi_1(f)$ is a Gödel-number of the function $\theta'(a) = \chi(a, \theta(a)) + 1$;

(ii) if for each $n$, $[e](n)$ is a Gödel-number of a recursive function $\theta_n(a)$ then $\psi_2(e)$ is a Gödel-number of the recursive function

$$
\theta(a) = \max \theta_n(a) + 1 = \max \{ [e](i) \}(a) + 1.
$$

Put $\theta < \zeta$ if $(Em)(n)(m \geq n \rightarrow \theta(n) < \zeta(n))$. Consider the functions $\rho_a$ associated with the $\psi_1, \psi_2$ of 2.6 by 2.4, with $q_1$ the Gödel number of the function $\lambda x(0)$. These have the property that if $c <_0 d$ then $\rho_c <_0 \rho_d$ (cf. 5.3 below). We thus refer to these $\rho_a$'s as constituting the majorizing hierarchy associated with $\chi$. Other results in this paper will depend on taking $\chi$ to be a function which satisfies $b \leq \chi(a, b)$ for all $a, b$. Some choices of such $\chi$ would be $\chi(a, b) = b$, $\chi(a, b) = (a + 1) \cdot b$, $\chi(a, b) = (a + 2)^b$, etc.; these lead to familiar number-theoretic majorizing relationships.

These hierarchies can be modified by taking $\rho_1$ to be any given recursive function. The results of this paper will still continue to hold for such modifications. We can further take $\rho_1$ to be an arbitrary function if the notion of recursiveness is replaced by that of recursiveness relative to $\rho_1$.

3. Completeness of primitive recursively expanding hierarchies.

3.1. Definition. By a hierarchy which is p.r. (primitive recursively) expanding with respect to certain relations $\leq_e$ ($e = 0, 1, 2, \ldots$) between unary functions, we understand an assignment of unary functions $\phi_x$ to each $d \in \mathbb{O}$ for which there are primitive recursive functions $T_r, C, S, L, M$ satisfying the following conditions:

(i) for any $\phi, \theta, \xi, \zeta$, if $\phi \leq_e \theta, \theta \leq_e \xi$ then $\phi \leq_{T_r, \xi, \zeta}$;

(ii) for any $d \in \mathbb{O}$ and any $k$,

$$
\lambda x(k) \leq C(k, d) \rho_d \ominus (k+1)\rho_d
$$

(iii) for any $d \in \mathbb{O}, \rho_a \leq L(e, d) \rho_b$;

(iv) for any $d, e$, and binary $\phi$ such that $3 \cdot 5^d \in \mathbb{O}$ and $\lambda x\phi(n, x) \leq [e](n) \rho_d[n]$ for all $n$, we have

$$
3 \cdot 5^M(e, d) \in \mathbb{O}, \quad |3 \cdot 5^M(e, d)| = |3 \cdot 5^d|, \quad [d](n) <_0 3 \cdot 5^M(e, d)
$$

for all $n$, and $\lambda x\phi(x, x) \leq L(e, d) \rho_d \cdot 5^M(e, d)$.

We say that the hierarchy is strictly expanding if for all $d \in \mathbb{O}$ and all $e, \rho_e \leq \rho_d$.

3.2. Theorem. The Kleene sub-recursive hierarchy is strictly p.r. expanding with respect to the relations $\subseteq_e$.

Proof. (i) A suitable function $T_r$ has been defined by Kleene in [6, pp. 70–71].
(ii) Here we can take \( C \) to be a simple function \( C(k) \) of \( k \) only, satisfying 
\[ \lambda x(x(k)) \subseteq C(x) \theta \] for any function \( \theta \).

(iii) Here we can take \( S(d) \) to be a certain constant \( s \) where \( \theta \subseteq s \lambda x[x(x)] \forall x \theta \) for any function \( \theta \).

(iv) In this case we can find \( M \) as a function \( M(d) \) of \( d \) only and \( L \) as a function \( L(e) \) of \( e \) only. \( M \) is chosen to satisfy 
\[ M(d)(n) = 2^{d(n)} = [d](n) \oplus 1 \theta, \] for all \( n \), and a preliminary (primitive recursive) \( L_1 \) is chosen to satisfy 
\[ L_1(e)(n, a) = 2^n \cdot 3^{a(n)} \cdot 4 \] for all \( n, a \). To see how \( L \) should be defined, suppose we had \( d, e, \phi \) satisfying the hypothesis of 3.1 (iv) with respect to the relations \( \subseteq \). Let \( \phi_\alpha = \lambda x \phi(x, x) \) for all \( n \). Then for each \( n, a \),
\[ \phi_\alpha(a) = [\alpha(n)] \phi_1(n)(a) = \rho_2(\alpha)(n) \cdot 3^n = \rho_2 \cdot 3^{n+\alpha}(2^n \cdot 3^{\lambda e(n)} \cdot 4) \] for all \( n, a \). Choose primitive recursive \( L(e) \) to satisfy 
\[ L(e)(n, a) = \theta(L_1(e)(a, a)) \] for all \( a, e, \theta \). We see by the preceding argument that for such \( L \), \( \lambda x \phi(x, x) \subseteq L(e) \rho_2 \cdot 3^{n+\alpha} \). That the expansion is strict is shown by Kleene in [6, p. 73].

3.3. **Theorem.** Let \( \chi(a, b) \) be recursive and \( b \leq \chi(a, b) \) for all \( a, b \). Then the majorizing hierarchy associated with \( \chi \) is strictly p.r. expanding with respect to the relations \( \subseteq \), when these are all taken to be the same relation \( \leq \), where \( \phi < \theta \mapsto (n) (\phi(n) < \theta(n)) \).

**Proof.** The condition (i) is obviously fulfilled.

(ii) Using \( \rho_2(\alpha) = \psi(a, \rho_e(\alpha)) + 1 \geq \rho_2(\alpha) + 1 \) for any \( e \in O \), and any \( a \), we easily prove by induction on \( k \) that \( i \leq \rho_{de+\alpha}(a) \) for any \( d \in O, a \) and \( i \). The first inequality also establishes (iii).

(iv) Here we can take \( M(e, d) = d \). For suppose \( \lambda x \phi(x, x) \leq \rho_d(n) \) for all \( n \). Then for any \( a \),
\[ \phi(a, a) < \rho_d(a) = \max_{0 \leq i \leq a} \rho_d(i) \] That the expansion is strict is obvious by the inequality used to prove (ii).

We assume throughout the remainder of this section that we are dealing with any one hierarchy of functions \( \rho \) (not necessarily recursive) p.r. expanding (not necessarily strictly) with respect to certain relations \( \leq \). We assume that \( Tr, C, S, L, M \) are some fixed primitive recursive functions satisfying 3.1 (i)–(iv) with these \( \rho \), \( \leq \).

The details of the proof of the completeness results which we shall give in
this section would not be essentially simplified by restricting attention to the
sub-recursive hierarchy, and would be simplified little more in the case of
majorizing hierarchies. On the other hand, the theorems hold even for further
(slight) generalizations of 3.1. For example, we could weaken 3.1 (ii) so that
$k+1$ is replaced by some primitive recursive $D(k, d)$.

3.4. Lemma. There is a primitive recursive function $N(d, e, i)$ such that for
any $d \leq 0$ and any $\phi$, if $\phi \leq e$ (as then $\phi \leq N(d, e, i) \rho \rho \rho \rho$, $\rho \rho \rho \rho$.

Proof. Take $N(d, e, 0) = e$, $N(d, e, i+1) = Tr(N(d, e, i), S(d \oplus i_0))$, for
any $d, e, i$.

Consider now any recursive function $\phi(a) = U(\mu y T_1(q, a, y))$, and let for
each $n \phi_n$ be the constant function $\lambda x \phi(n)$. By 3.1 (ii), each $\phi_n \leq_r \rho_n$
certain $f, h$, namely $f = C(\phi(n), 1)$ and $h = 1 \oplus (\phi(n) + 1)0 = (\phi(n) + 1)0$. However, in
general these $f, h$ are not chosen as primitive recursive functions of $n$. Our
main argument towards completeness, which now follows, shows that, never-
theless, certain other $f, h$ can be chosen primitive recursively to satisfy
$\phi_n \leq_r \rho_n$. This, when combined with the limit condition 3.1 (iv), will allow
us to obtain a similar result for $\phi$ itself.

3.5. Theorem. There are primitive recursive functions $f = F(q, b, n),
h = H(q, b, n)$ such that whenever $(\forall y) T_1(q, n, y), \phi = \lambda x U(\mu y T_1(q, x, y)),$
$\phi_n = \lambda x \phi(n)$ and $b \leq 0$, then

(i) $h \leq O, b < o h, |h| = |b| + \omega \cdot m$ for some $m > 0$, and

(ii) $\phi_n \leq_r \rho_n$.

Proof. We shall construct certain primitive recursive functions of $q, b, n, k$
and $i$. Considering $q, b, n$ as parameters, we concentrate on the definition of
these as functions of $k, i$. Using the primitive recursive functions $Sb^n$ of
[6, p. 75], we have $[Sb^n(z, y)](x) = [z](y, x)$ for any $x, y, z$. We shall write
$P_n$ for $Sb^n(z, y)$. (This notation will be used only in this proof.) We consider
three primitive recursive predicates of $k$ (and, implicitly, also of $q, n$):

\[
\begin{align*}
\text{Sec}^{(0)}(k) & \iff (\forall y) y < k T_1(q, n, y), \\
\text{Sec}^{(1)}(k) & \iff T_1(q, n, k) \& (\forall y) y < k T_1(q, n, y), \\
\text{Sec}^{(2)}(k) & \iff (\forall y) y < k T_1(q, n, y).
\end{align*}
\]

(Adapting the terminology of [8], we might say of these three cases, success-
vively, that $k$ is past secured, $k$ is just secured, and $k$ is unsecured.) Using
2.1(ii), we now find $d, e$, satisfying the following two conditions for all $k, i$:

\[
\begin{align*}
[d](k, i) = \begin{cases} 
0 & \text{if Sec}^{(0)}(k), \\
\mu \mu (U(k) + 1)0 \ominus i_0 & \text{if Sec}^{(1)}(k), \\
3 \cdot 5^{M(1k+1.4k+1)} \ominus i_0 & \text{if Sec}^{(2)}(k).
\end{cases}
\end{align*}
\]
1962] CLASSIFICATIONS OF RECURSIVE FUNCTIONS 109

\[
[e](k, i) = \begin{cases} 
0 & \text{if } \text{Sec}^{(0)}(k), \\
N(b \oplus (U(k) + 1)0, C(U(k), b), i) & \text{if } \text{Sec}^{(1)}(k), \\
N(3 \cdot 5^M(e+1,d+i), L(e_{k+1}, d_{k+1}), i) & \text{if } \text{Sec}^{(2)}(k).
\end{cases}
\]

Now suppose \((Ey)T_1(q, n, y)\) and \(b \in O\). Define \(\phi\) and \(\phi_n\) as in the statement of the theorem. Let \(k_0 = \mu y T_1(q, n, y)\). We shall prove by induction on \(j\) that

(4) If \(j \leq k_0, k = k_0 - j,\) and \(i\) is arbitrary, then

(a) \(|[d](k, i)| = |b| + \omega \cdot j + \begin{cases} U(k_0) + 1 + i & \text{if } j = 0, \\
i & \text{if } j \neq 0, \end{cases}\)

and (b) \(\phi_n \leq [e](0, 0) \rho([d](k, i)) \)

For \(j = 0\), we have \(k = k_0\), so \(\text{Sec}^{(1)}(k)\). 4(a) is clearly true in this case. By 3.1(ii), \(\phi_n = \lambda x U(k_0) \leq C(U(k), b) \rho_0 \oplus U(k_0 + 1)\), hence \(\phi_n \leq [e](0, 0) \rho([d](k, 0))\) by (2), (3) and 3.4.

Suppose (4) true for \(j\); we shall now show it true for \(j + 1\). Suppose \(j + 1 \leq k_0\) and let \(k = k_0 - (j + 1)\). We shall thus use (4)(a), (b) applied to \(j, k + 1\). We have from these \(3 \cdot 5^M_{k+1} \in O, b < 0, 3 \cdot 5^M_{k+1} = |b| + \omega \cdot (j + 1)\), and \(\phi_n \leq [e](0) \rho([d](k+1))\) for all \(i\). Let \(\psi(i, x) = \phi_n(x) = \phi(n)\) for all \(i, x\). Hence also \(\lambda x \psi(i, x) \leq [e] \rho([d](k+1))\) for all \(i\). But then by 3.1(iv),

\[
3 \cdot 5^M(e_{k+1}, d_{k+1}) \in O, \quad 3 \cdot 5^M(e_{k+1}, d_{k+1}) = |3 \cdot 5^M_{k+1}|, \quad [d_{k+1}(i)] < 0 3 \cdot 5^M(e_{k+1}, d_{k+1}) \quad \text{for all } i,
\]

and

\[
\lambda x \psi(x, x) \leq L(e_{k+1}, d_{k+1}) \rho_{3 \cdot 5^M(e_{k+1}, d_{k+1})}.
\]

Since in this case \(k < k_0\), and hence \(\text{Sec}^{(2)}(k)\), and since also \(\phi_n = \lambda x \psi(x, x)\), we see by (2), (3) and 3.4 that (4) is also true for the case \(j + 1, k\).

As we remarked at the beginning of the proof, \(q, b, n\) were taken as parameters in the definition of \([d](k, i), [e](k, i)\). Hence \(f = [e](0, 0)\), \(h = [d](0, 0)\) determine \(f\) and \(h\) as primitive recursive functions of \(q, b, n\). When the hypotheses of our theorem concerning \(q, b, n, \phi\) are met, we have \(T_1(q, n, k_0)\), hence \(k_0\) is the Gödel number of a deduction from the system of equations with number \(q\), and thus \(k_0 \neq 0\). Taking \(j = k_0\) in (4) thus gives us the desired result.

3.6. Theorem. There are primitive recursive functions \(e = E(q, b)\) and \(d = D(q, b)\) such that whenever \((x)(Ey)T_1(q, x, y)\), \(\phi = \lambda x U(\mu y T_1(q, x, y))\), and \(b \in O\), then \(d \in O, b < 0 d, \quad |d| = |b| + \omega^2\) and \(\phi \leq e \rho_d\).

Proof. Let \(F, H\) be chosen to satisfy the conditions of 3.5. Define primitive recursive \(H_1\) by \(H_1(q, b, 0) = b, H_1(q, b, n + 1) = H(q, H_1(q, b, n), n)\). Treating
q, b as parameters, choose h with \( [h] = \lambda x H_1(q, b, x, x) \). Also choose f with 
\( [f] = \lambda x F(q, H_1(q, b, x), x) \). Thus h, f are primitive recursively chosen as functions of q, b. Let \( d = 3 \cdot 5^m \) and \( e = L(f, h) \). To see that these satisfy the required conditions, suppose \( (x)(E y) T_1(q, x, y) \) and that \( e \in \omega \) for some \( m > 0 \); furthermore, \( b \in (h)(0) \) and \( (h)(0) = b + \omega \cdot m \) for some \( m \). Thus \( 3 \cdot 5^m \in \omega \), \( b \in (h)(0) \) and \( 3 \cdot 5^m = b + \omega^2 \). Also by 3.5, \( \phi_n = \lambda x \psi(n, x) \leq \lambda (\omega(n)) \rho_{(h, n)} \) for each \( n \). Put \( \psi(n, x) = \phi(n) \) for all \( n, x \). Then also \( \lambda x \psi(x, x) \leq \lambda (\omega(n)) \rho_{(h, n)} \).

By a path \( P \) within \( \omega \) we understand a subset of \( \omega \) simply (and hence well-) ordered by \( < \), and containing with any \( d \) all predecessors of \( d \). \( |P| \) denotes the order type of this path.

3.7. Theorem. Suppose \( \kappa \) is any ordinal with \( \kappa \leq \omega \). Then there exist \( (N_0) \) paths \( P_\kappa \) within \( \omega \) such that \( |P_\kappa| = \kappa + \omega \) for \( \kappa < \omega \), \( |P_\omega| = \omega \), such that for any recursive function \( \phi \) there exists a \( d \in P_\kappa \) and an \( e \) with \( \phi \leq \rho_d \cdot P_\kappa \) can be chosen to be arithmetically definable (in fact, in a 4-quantifier form) for \( \kappa < \omega \), and recursive in \( \omega \) for \( \kappa = \omega \).

Proof. Let \( n_0, \ldots, n_n, \ldots \) be an enumeration of all \( n \) such that \( (x)(E y) T_1(q, x, y) \); specifically each \( n \) is the least \( n > n_{n-1} \) (\( n = 0 \)) such that \( (x)(E y) T_1(q, x, y) \). The predicate \( Q(n, a) \) which holds if and only if \( a = n \) is arithmetically definable in the four alternating quantifier forms beginning with the existential quantifier.

To prove the theorem, consider first the case \( \kappa < \omega \). Choose \( b \in \omega \), \( |b| = \kappa \). Let \( D, E \) be the primitive recursive functions of 3.6. Define \( d_0 = b, d_{n+1} = D(q_n, d_n) \), and define \( e_n = E(q_n, d_n) \). Thus \( d_n < d_{n+1} \) and \( d_{n+1} = d_n + \omega^2 \). The path \( P_\kappa \) can be chosen in this case to be the set of \( x < d_n \). Using the evaluation of the predicate \( Q(n, a) \) it is seen that \( P_\kappa \) can also be defined in the same form. There is no generality lost by taking \( \kappa \geq \omega \). By choosing \( N_0 \) b's with \( |b| = \kappa \), we obtain \( N_0 \) distinct \( P_\kappa \)’s.

The proof for the case \( \kappa = \omega \) is obtained by a slight modification. Let \( b_0, \ldots, b_n, \ldots \) be an enumeration of \( \omega \); the predicate \( B(n, a) \) which holds when \( a = b_n \) is recursive in \( \omega \). Define \( d_0 = b_0, d_{n+1} = D(q_n, d_n \oplus b_n) \), and define \( e_n = E(q_n, d_n \oplus b_n) \). Thus \( d_n \leq d_{n+1} \) and \( d_{n+1} = d_n + \omega^2 \). The path \( P_\omega \) is again defined as the set of \( x < d_n \). Since \( |b_n| \leq |d_n| \) for all \( n \), \( |P_\omega| = \omega \). Without loss of generality we can take \( |b_0| = \omega \); by altering the enumeration of \( \omega \) for different choices of \( b_0 \) we obtain \( N_0 \) distinct \( P_\omega \)’s.

Uniqueness in hierarchies \( \rho_d \) with respect to relations \( \leq \) is can be said to hold at level \( \kappa < \omega \) if for all \( d, d' \in \omega \) with \( |d| = |d'| = \kappa \) there exist \( e, f \) with \( \rho_d \leq \rho_e, \rho_d \leq \rho_f \). The following nonuniqueness result is obtained directly from 3.6 (cf. also [1; 9]).
3.8. Corollary. Suppose the given hierarchy is strictly p.r. expanding and that for any \( c, d \in O \), \( c \leq_0 d \rightarrow (Ee) \rho_e \leq_0 \rho_d \). Then for any \( d \in O \), \( |d| \geq \omega^2 \), there exists \( d' \in O \) with \( |d'| = |d| \) and \( (e) \{ \rho_e \leq_0 \rho_d \} \).

Proof. Let \( |d| = \omega^2 + \kappa \), and let \( b \in O \), \( |b| = \kappa \). By 3.6 we can find \( h \in O \), \( |h| = \omega^2 \), and \( f_1 \) such that \( \rho_{g_1} \equiv_0 f_1 \). Let \( d' = h \oplus b \); thus \( h \leq_0 d' \) and \( |d'| = |d| \).

By hypothesis there is \( f_2 \) with \( \rho_{f_2} \equiv_0 \rho_{d'} \), hence by 3.1(i) there is \( f \) with \( \rho_{f_2} \equiv_0 \rho_{d'} \).

If for any \( e \), \( \rho_{d'} \equiv_0 \rho_e \), we would have \( \rho_{d'} \equiv_0 \rho_e \) for certain \( e \), contradicting the strictness of the expansion.

As we remarked in \( \S 2 \), the condition \( c \leq_0 d \rightarrow (Ee) \rho_e \leq_0 \rho_d \) is met by the Kleene sub-recursive hierarchy with respect to the relations \( \leq_0 \). As shown in [1, pp. 87–91] that uniqueness holds in this hierarchy for \( |d| < \omega^2 \) and fails at \( |d| = \omega^2 \).

To apply 3.8 to the majorizing hierarchies, we consider the relation \( \phi \equiv_0 \theta \rightarrow (Em)(n)(n \geq m \rightarrow \phi(n) \equiv \theta(n)) \) instead of the relation \( \phi \equiv_0 \theta \) of complete majorizing used to prove 3.6. This still has the property of strictness, \( \rho_{d'} \equiv_0 \rho_d \) and, as pointed out in \( \S 2 \), it satisfies \( c \leq_0 d \rightarrow \rho_c \equiv_0 \rho_d \). If for any \( e \), \( \rho_e \equiv_0 \rho_d \), we would have \( \rho_{d'} \equiv_0 \rho_e \) for certain \( e \), contradicting the strictness of the expansion.

4. Classification of certain hierarchies below \( \omega^2 \). In the first part of this section we give a classification, in terms of the notion of ordinal recursion, of the functions \( \rho_e \) in the Kleene sub-recursive hierarchy for \( |d| < \omega^2 \). This part of our work has been carried out in collaboration with W. W. Tait.

Consider a primitive recursive well-ordering \( \prec \) of the natural numbers in which 0 is the first element. Put

\[
(4.1) \quad x \prec a = \begin{cases} x & \text{if } x \prec a, \\ 0 & \text{otherwise}. \end{cases}
\]

A function \( \phi(x) \) is said to be defined by nested \( \prec \)-recursion from \( \xi_1, \ldots, \xi_m \) if it satisfies

\[
(4.2) \quad \phi(0) = k, \\
\phi(a + 1) = \gamma(a),
\]

where \( \gamma(a) \) is built up by composition from the functions \( \xi_1, \ldots, \xi_m \) and the function \( \phi \), but where every application of \( \phi \) has the form \( \phi(s \prec (a + 1)) \). This is said to be an ordinary, or unnested, recursion if \( \gamma(a) \) has the form \( \tau(a, \phi(s \prec (a + 1))) \), where \( \tau, \sigma \) are built up from \( \xi_1, \ldots, \xi_m \) alone. Generalization of this notion to functions of several variables is fairly direct. (The notion of nesting corresponds to Péter's "eingeschachtelte" recursions of [12, §10].) A function is said to be definable by ordinary \( \prec \)-recursion (by nested \( \prec \)-recursion) if it is the end term of a sequence of functions each of
which is obtained from preceding functions in the sequence either by one of the usual schemas for primitive recursion or by the schema (4.2), in one or more variables, for ordinary $\vartriangleleft$-recursion (for nested $\vartriangleleft$-recursion).

We deal here only with "standard" or "natural" well-orderings $\vartriangleleft$, which notion is well understood at the very least for ordinals $\leq \varepsilon_0$. We might specifically take for these the orderings defined in [4, p. 361], or consider orderings satisfying certain minimal conditions, as in [15, 1.2]. The classification of (part of) the class of recursive functions by such orderings does not collapse at low ordinals, in contrast to [11; 13]. If $\alpha$ is the order type of $\vartriangleleft$, we shall speak of (ordinary or nested) $\alpha$-recursion. The $\omega^\alpha$-recursions thus correspond to the "k-fache" recursions of [12, §§11–12]; the nested $\omega^\alpha$-recursions correspond to what Axt calls $k$-recursive functions in [1, p. 93]. The main fact that we shall use for such standard $\alpha$-recursions is the following proved by Tait in [15, Theorem 2], for $\alpha \geq \omega$: if a function $\phi$ is definable by nested $\alpha$-recursion then it is also definable by ordinary $\omega^\alpha$-recursion. (He has also shown in [15] that, when $\omega \cdot \alpha = \alpha$, the converse is also true.)

4.3. Theorem. The functions $\rho_d$ of the Kleene sub-recursive hierarchy are all nested $\omega^\alpha$-recursive, hence all ordinary $\omega^\alpha$-recursive for $d \in \Omega$, $|d| < \omega^2$.

Proof. It is more convenient here to return to Kleene's definition of his hierarchy in [6] as consisting of functions $h_d(b, a)$ satisfying

\begin{align*}
  h_1(b, a) &= 0, \\
  h_d(b, a) &= [b]^{h_{d-1}(a)}(a) \quad \text{for } d \neq 0, \\
  h_{\omega^\alpha}(b, a) &= h_{[d]}(b_{(0)}(0, a)).
\end{align*}

By the uniqueness result of Axt [1], it is sufficient to classify the functions $h_d$ corresponding to the "natural" notations $|d| < \omega^2$, all others at these levels being primitive recursive in these particular functions. Thus to each $m, k$ we associate $d_{m,k}$ with $|d_{m,k}| = \omega \cdot m + k$, $d_{m,k} <_0 d_{m_1,k_1}$ if and only if $|d_{m,k}| < |d_{m_1,k_1}|$.

We shall now define a sequence of functions $H_m(k, b, a)$ such that $h_{d_{m,k}}(b, a) = H_m(k, b, a)$ for all $m, k$.

\begin{align*}
  (i) & \quad H_0(0, b, a) = 0, \\
  (ii) & \quad H_0(k + 1, b, a) = [b]^{H_0(k,b,a)}(a), \\
  (i) & \quad H_{m+1}(0, b, a) = H_m(b_{(1)}, b_{(0)}, a), \\
  (ii) & \quad H_{m+1}(k + 1, b, a) = [b]^{H_{m+1}(k,b,a)}(a).
\end{align*}

We next analyze the form of (2)(ii), (3)(ii). In general, the definition of $\phi(b, a) = [b]^{\theta}(a)$ from given binary $\theta$ can be put in the form

\begin{align*}
  \phi(0, a) &= \theta(a_{(0)}, a_{(1)}), \\
  \phi(b + 1, a) &= \chi\left(b, a, \phi\left(\tau_0(b), \tau_1\left(a, b, \prod_{i \leq b} \phi_i^{(i,a)}, \phi(b + 1, [a/2])\right)\right)\right),
\end{align*}
where \( \tau_0(b) < b + 1 \), and \( \tau_1 \) is a function of \( b \) only when \( a = 0 \). This can be obtained from [6, p. 74]. Here \( \chi, \tau_0, \tau_1 \) are certain primitive recursive functions. Assigning the ordinal \( \omega \cdot b + a \) to \( (b, a) \) shows that this is a definition of \( [b]^{\tau}(a) \) by nested \( \omega^2 \)-recursion from \( \theta \). Assigning the ordinal \( \omega^2 \cdot k + \omega \cdot b + a \) to \( (k, b, a) \) in (2), and replacing the equation (2)(ii) by two equations obtained from (4) by substituting \( \lambda y x H_0(k, y, x) \) for \( \theta \) and \( \lambda y x H_0(k + 1, y, x) \) for \( \phi \) shows that \( H_0 \) is nested \( \omega^3 \)-recursive. Similarly, \( H_{m+1} \) is nested \( \omega^3 \)-recursive in \( H_m \).

Hence induction and Tait's result shows that each \( H_m \) is ordinary \( \omega^\infty \)-recursive. It follows that the same is true of each function \( d_{m,k} = \lambda y x H_m(k, y, x) \).

Axt has shown in [1, p. 99] that the converse to 4.3 is true, i.e., that every nested \( \omega^2 \)-recursive function is primitive recursive in one of the \( \rho_d \) for \( |d| < \omega^2 \), and in fact more generally for nested \( \omega^{k+1} \)-recursions and \( |d| < \omega^k \). It is clear how 4.3 can be extended to the classification of \( \rho_d \) for "natural" \( d \) with \( |d| < \omega^k \). These various results constitute a partial answer to Kleene's problem P 237 in [6, p. 77].

4.4. Theorem. The functions \( \rho_d \) of the majorizing hierarchy associated with a function \( \chi(a, b) \) are all primitive recursive in \( \chi \) for \( d \in O, |d| < \omega^2 \).

Proof. For any \( d \in O, |d| < \omega^2 \), there are only finitely many limit notations \( 3 \cdot 5^e \leq d \). It suffices then to consider any sequence \( 3 \cdot 5^e, \ldots, 3 \cdot 5^{e_n}, \ldots \) (not necessarily primitive recursive) with \( 3 \cdot 5^{e_n} = \omega \cdot n \) and \( 3 \cdot 5^{e_n} < 3 \cdot 5^{e_{n+1}} \) and to show that for any \( d < 3 \cdot 5^{e_n} \) for some \( n \), we have \( \rho_d \) primitive recursive in \( \chi \). We regard this sequence as fixed throughout the following.

Define the following primitive recursive functions \( M, E \) (no relation to functions used in §3) by course-of-values recursion.

\[
M(2d) = M(d), \quad M(a) = a \quad \text{otherwise};
\]

\[
E(2d) = E(d) + 1, \quad E(a) = 0 \quad \text{otherwise}.
\]

Thus if \( d \in O, |d| < \omega^2 \), \( M(d) \) is the maximum limit notation \( 3 \cdot 5^e \) which is \( \leq d \), or 1 if there is no such. Further \( d = M(d) \oplus (E(d))_0 \), so \( E(d) \) measures the excess of \( d \) over this notation. We shall also need an iteration of the function \( \chi(a, b) + 1 \),

\[
\chi^*(0, a, b) = b, \quad \chi^*(n + 1, a, b) = \chi(a, \chi^*(n, a, b)) + 1.
\]

\( \chi^* \) is primitive recursive in \( \chi \).

Let \( L_n = \{d : d < 3 \cdot 5^{e_n}\} \). We shall prove by induction on \( n \) that

3. There exists a function \( \phi_n \), primitive recursive in \( \chi \), such that for every \( d \in L_n \) and every \( a \),

\[
\rho_d(a) = \phi_n\left(a, d, \prod_{i \leq a} p_i^{[e_i(i)]}, \ldots, \prod_{i \leq a} p_i^{[e_{a-1}(i)]}\right).
\]

The defining conditions for the majorizing hierarchy are \( \rho_1(a) = 0 \),

\[
\rho_2d(a) = \chi(a, \rho_d(a)) + 1, \quad \rho_{2 \cdot 4^e}(a) = \max_{0 \leq i \leq a} \rho_{d_{i,j}}(a) + 1.
\]
Using (1) and (2) we have for any $d \in O$, $|d| < \omega^2$,

(4) \[ \rho_d(a) = \chi^*(E(d), a, \rho_M(d)(a)). \]

Thus for the case $n = 1$, we can take $\phi_1(a, d) = \chi^*(E(d), a, 0)$. Suppose now that (3) is true for $n$, and let us prove it for $n + 1$. If $d \in L_{n+1}$, we have $d \in L_n \iff M(d) \neq 3 \cdot 5^n$. We can define the desired function $\phi_{n+1}$ by separating the cases $d \in L_n$, $d \in L_{n+1} - L_n$. Set

(5) \[ \psi_n(a, x_1, \ldots, x_{n-1}, y) = \max_{0 \leq i \leq n} \phi_n(a, y_{(i)}, x_1, \ldots, x_{n-1}) + 1. \]

Then we define

(6) \[ \phi_{n+1}(a, d, x_1, \ldots, x_n) = \begin{cases} 
\phi_n(a, d, x_1, \ldots, x_{n-1}) & \text{if } M(d) \neq 3 \cdot 5^n, \\
\chi^*(E(d), a, \psi_n(a, x_1, \ldots, x_{n-1}, x_1)) & \text{if } M(d) = 3 \cdot 5^n.
\end{cases} \]

Then by induction hypothesis $\phi_n$ and hence $\psi_n$ and $\phi_{n+1}$ are primitive recursive in $\chi$. To see that (3) continues to hold true for $n + 1$, we need only consider the case $M(d) = 3 \cdot 5^n$. By (4), it is sufficient to see that

(7) \[ \rho_{3 \cdot 5^n}(a) = \psi_n\left(a, \prod_{i \leq a} \rho_i^{[c_1](i)}, \ldots, \prod_{i \leq a} \rho_i^{[c_{n-1}](i)}\right). \]

But the right side here is just

\[ \max_{0 \leq i \leq a} \phi_n\left(a, [c_n](j), \prod_{i \leq a} \rho_i^{[c_1](i)}, \ldots, \prod_{i \leq a} \rho_i^{[c_{n-1}](i)}\right) + 1, \]

which, since each $[c_n](j) <_O 3 \cdot 5^n$, i.e., $[c_n](j) \in L_n$, is by (3) for $n$ the same as $\max_{0 \leq i \leq a} \rho_{[c_n](j)}(a) + 1$.

Thus (7) is proved and the induction is complete. Now for any particular $d \in O$, $|d| < \omega^2$, (3) gives the value of $\rho_d(a)$ as a function, primitive recursive in $\chi$, of $a$, $d$ and the values of the primitive recursive functions $[c_1], \ldots, [c_{n-1}]$ obtained from all limit notations which are $\leq_O d$. This proves the theorem.

5. Nonstandard extensions of hierarchies. In this section we use the nonstandard extension $O^*$ of $O$, defined in [3] (restricted here to primitive recursive fundamental sequences) to obtain an incompleteness result for hierarchies and to give some information on the structure of the set of recursive functions with respect to certain partial orderings.

We shall briefly describe some of the notions and results of [3] as adapted to the present situation. We put a set $A \in \Pi$ if it can be defined in the form $n \in A \iff (\alpha)(Ex)R(n, \alpha(x))$ with primitive recursive $R$, $A \in \Sigma \iff \overline{A} \in \Pi$, and $A \in H.A. \iff A \in \Pi \cap \Sigma$ (H.A. = hyperarithmetical). We put $d \in M$ if $C'(d)$ is
simply ordered by $\prec$, $1 \in C'(d)$ contains with each $x$ also each $y \prec x$, and if for all $x \in C'(d)$, either $x = 1$, $x = 2^{x(0)}$ where $x(0) \neq 0$, or $x = 3 \cdot 5^{x(w)}$ where $[x(0)](y) < [x(0)](y+1)$ for all $y$. We put $d \in O^*$ if $d \in M$ and for all $A \in H.A.$, $A \cap C'(d) \neq \Lambda$ implies $A \cap C'(d)$ has a least element under $\prec$. It is shown in [3, §3], that $O \subseteq O^*$, $O^* \subseteq \Sigma$. On the other hand, $O \subseteq \Pi - \Sigma$. In fact for any $A \in \Pi$ we can find primitive recursive $\xi$ such that $(x) [x \in A \leftrightarrow \xi(x) \in \Omega]$, the proof of this can be directly adapted from Kleene’s proof of the corresponding theorem for the usual definition of $O$ in [8]. Hence we also have here the result of [3, 3.6] that for any $a \in O$ we can find $d \in O^* - O$ such that $a \prec d$. The argument of [3, 3.7] also served to show that for any such $d$, $P = O \cap C'(d)$ is a path through $O$ with $P \subseteq \Pi$. The only thing to check in that proof for the present $O$ is that for each $c \in O$, $\{x: x \in O \& |x| < |c| \} \subseteq H.A.$ This is true for the full $O$ by Spector [14, p. 158]. However, the present $O$ is in 1-1 correspondence with the intersection of an arithmetically defined set (similar to $M$ above) with the full $O$, and this correspondence is easily used to carry the result over. Hence we obtain directly the existence, as in [3, 4.4] of $\omega$ paths $P$ through $O$ such that $P \subseteq \Pi$. Moreover, it is useful to note, just as in [3, 3.8], that for any such $P$ there is a $d \in O^* - O$ with $P = O \cap C'(d)$.

In any strictly expanding hierarchy (3.1) we have a relation $\phi \preceq \psi$ defined by $(\phi(e)) \preceq \phi \preceq \psi$; this has the property $\rho(e) \preceq \rho(e)$ and $\rho(e) \preceq \rho(d)$ for each $d \in O$. We need rather less of the conditions on a hierarchy of 3.1 for the developments of this section, but a little more on the relation $\preceq$. Throughout the remainder of this section, we assume $\phi_1$ is any fixed Gödel-number of a recursive function and that $\psi_1, \psi_2$ are any fixed primitive recursive functions satisfying the conditions 2.4(i), (ii). We take $\phi, \psi$ to be primitive recursive functions satisfying the conclusion of 2.4 and $\rho(d) = \lambda x [\phi(d)](x)$ for any $d$.

5.1. Definition. A relation $\ll$ between functions is said to conform with $\psi_1, \psi_2$ if $\ll$ is transitive and irrelextive and if

(i) whenever $f$ is the Gödel-number of a recursive function then $\{f\} \ll \{\psi_1(f)\}$,
(ii) whenever $[e(n)]$ is the Gödel-number of a recursive function for each $n$ and $[e]([e(n)]) \ll [e]([e(n+1)])$ then $\{[e]([n])\} \ll \{[\psi_2(e)]\}$, and
(iii) the relation $[e] \ll [f]$ is a hyperarithmetical relation between $e, f$.

We note, for applications, the following easily derived result.

5.2. Lemma. (i) The relation $\subseteq$ conforms with any functions $\psi_1, \psi_2$ satisfying 2.5(i), (ii).
(ii) The relation $\prec$ (of majorizing) conforms with any functions $\psi_1, \psi_2$ satisfying 2.6(i), (ii) with respect to any given recursive $\chi$.

We now assume throughout the following that $\ll$ is any relation which conforms with the general $\psi_1, \psi_2$ we are considering here.

Just as is shown in [3, 5.2] we see that $O^*$ is the intersection of all $X \subseteq H.A.$ satisfying the following closure conditions:

(i) $1 \in X;$
(ii) if \( c \in X \) then \( 2^c \in X \);
(iii) if \( \{ d \} (n) \in X \) & \( \{ d \} (n) < \{ d \} (n+1) \) then \( 3 \cdot 5^d \in X \).

This characterization of \( O^* \) permits us to make inductive proofs, in the usual style, that various hyperarithmetical properties hold for all \( d \in O^* \). In this way, we easily obtain the following from 2.4 and 5.1.

5.3. Lemma. (i) For any \( d \in O^* \), \( \rho_d \) is a recursive function.
(ii) For any \( c, d \in O^* \), \( c < d \) \( \iff \) \( \rho_c \lesssim \rho_d \).

Here 5.3(ii) generalizes the statements of §2 that, for the sub-recursive hierarchy \( c <_o d \rightarrow \rho_c \subseteq \rho_d \), and for the majorizing hierarchy \( c <_o d \rightarrow \rho_c < \rho_d \). These results now lead us directly to the following incompleteness theorem for certain paths in hierarchies (cf. [3, 2.5], for a corresponding incompleteness theorem for progressions of theories).

5.4. Theorem. For any path \( P \) through \( O \), \( P \in \Pi \), we can find a recursive function \( \theta \) such that \( \rho_c \not< \theta \), and hence \( \theta \not< \rho_c \), for all \( c \in P \).

Proof. As we noted earlier, \( P = O \cap C'(d) \) for a certain \( d \in O^* - O \). We take \( \theta = \rho_d \) and apply 5.3 and the transitivity and irreflexivity of \( \ll \).

We shall now devote the remainder of the paper to a proof of an essentially new result, namely that there is a subset of \( O^* \) densely ordered by \( \prec \). This, via 5.3(ii), thus gives us some information regarding the structure of \( \ll \) on the set of recursive functions. We first need an extension of ordinal notation arithmetic to \( O^* \). The reason for this will be seen in connection with 5.16–5.18 below.

We wish to introduce operations corresponding to addition, multiplication, and exponentiation of ordinals. We already have a \( \oplus \) operation and, for uniformity, repeat the definition of this in 5.5(i) next. In order to apply a certain general result below (5.14) insuring the proper growth of these functions, we modify slightly the usual definitions of the other operations at the initial values.

5.5. Definition. \( \oplus, \circ, \text{ and } \circ \), and \( \nu_1, \nu_2, \nu_3 \) are chosen by 2.3 to be binary primitive recursive functions satisfying the following conditions for all \( a, d \):

(i) \( a \oplus 1 = a, \ a \oplus 2^d = 2^{\circ a^d}(d \neq 0), \ a \oplus 3 \cdot 5^d = 3 \cdot 5^d(a, d) \) where

\[
\{ v_1(a, d)(n) = a \oplus [d](n) \};
\]

(ii) \( a \circ 1 = a, \ a \circ 2^d = (a \circ d) \oplus a \ (d \neq 0), \ a \circ 3 \cdot 5^d = 3 \cdot 5^d(a, d) \) where

\[
\{ v_2(a, d)(n) = a \circ [d](n) \};
\]

(iii) \( a^{\circ 1} = a, \ a^{\circ 2^d} = (a^{\circ d}) \circ a \ (d \neq 0), \ a^{\circ 3 \cdot 5^d} = 3 \cdot 5^d(a, d) \) where

\[
\{ v_3(a, d)(n) = a^{\circ [d](n)} \}.
\]

More generally:

5.6. Definition. Let \( \theta(a, b) \) be any primitive recursive function. Choose primitive recursive \( \sigma(a, d), \nu(a, d) \) by 2.3 satisfying:

(i) \( \sigma(a, 1) = a; \)
(ii) \(\sigma(a, 2^d) = 3 \cdot 5^d \) for \( d \neq 0 \);

(iii) \(\sigma(a, 3 \cdot 5^d) = 3 \cdot 5^d(a, d)\) where \( (n) \{ [\nu(a, d)](n) = \sigma(a, [d](n)) \} \).

We shall refer to \(\sigma\) as being the function determined by notation recursion from \(\nu\) via \(\nu_1\).

Thus we see that, for suitable \(\nu_1, \nu_2, \nu_3\), if we set \(\sigma_0(a, b) = 2^a, \sigma_1(a, b) = a \oplus b, \sigma_2(a, b) = a \circ b, \sigma_3(a, b) = a^b\), then each \(\sigma_{i+1}\) is determined by notation recursion from \(\sigma_i\), via \(\nu_{i+1}\).

It is seen that \(a \circ b, a^b\) correspond respectively to the operations \(a(1 + b)\) and \(a \cdot (1 + a)^b\) on ordinals; these are strictly increasing functions of \(b\) for \(a \geq 1\).

We wish to show that \(O^*\) is closed under the operations \(\oplus, \circ, ^\circ\) (for \(a > 1\)), and that these have various properties on \(O^*\). We might expect an inductive proof on \(O^*\) of these properties. However, closure of \(O^*\) under such operations is not a hyperarithmetic property. It is necessary therefore to generally prove something stronger.

### 5.7. Definition

Let \(X\) be any set, \(\theta(a, b)\) any function. We write \(\text{Cl}(X)\) if the following conditions (i)-(v) hold:

(i) \(1 \in X\);

(ii) \(d \in X \rightarrow 2^d \in X\);

(iii) \( (n) \{ [d](n) \in X \land [d](n) < [d](n + 1) \} \rightarrow 3 \cdot 5^d \in X \);

(iv) \(d \in X \land c < d \rightarrow c \in X\);

(v) \(d \in X \rightarrow 1 \leq d\).

If, in addition, the following conditions (vi), (vii) or (vi), (viii) hold, we write \(\text{Cl}^*(X)\) or \(\text{Cl}^*_1(X)\), respectively:

(vi) \(a, b \in X \land 1 < a \rightarrow \theta(a, b) \in X\);

(vii) \(a, c \in X \land 1 < a \land b < c \rightarrow \theta(a, b) < \theta(a, c)\);

(viii) \(a, b \in X \land 1 < a \land 1 < b \rightarrow a < \theta(a, b)\).

As we remarked earlier, it has been proved in [3] that \(O^*\) is the intersection of all sets \(X \in H.A.\) satisfying (i)-(iii). Since the set \(M\) is arithmetical, each \(X \cap M \in H.A.,\), and it is easily seen that \(\text{Cl}(X \cap M)\). Hence we have

\[
(5.8) \quad O^* = \cap X[\text{Cl}(X) \land X \in H.A.].
\]

The following is easily obtained from 5.7.

### 5.9. Lemma

Let \(\Gamma\) be any collection of sets, \(\theta(a, b)\) any function. If for each \(X \in \Gamma\) we have \(\text{Cl}(X)\) then \(\text{Cl}(\cap X \in \Gamma)\). The same holds true for each of "\(\text{Cl}^*\), "\(\text{Cl}^*_1\)" instead of "\(\text{Cl}\)."

### 5.10. Definition

Let \(X\) be any set, \(\sigma(a, b)\) any function. We put

\[
X/\sigma = \{ d : d \in X \land (a)(b)(c) [a \in X \land 1 < a \land c \leq d \rightarrow \sigma(a, c) \in X \land (b < c \rightarrow \sigma(a, b) < \sigma(a, c))] \}.
\]
It is seen that if \( X \in \text{H.A.} \) then \( X/\sigma \in \text{H.A.} \). Actually, we need a little more. A set \( X \in \text{H.A.} \) if and only if there exist \( e_0, e_1 \) such that for all \( \alpha \)

\[
a \in X \leftrightarrow (\alpha)(Ey)T_1^\alpha(e_0, a, y) \leftrightarrow (E\alpha)(y)T_1^\alpha(e_1, a, y).
\]

For any number \( f \), let \( L_f = \{ x : (\alpha)(Ey)T_1^\alpha(f, x, y) \} \). Put \( \varepsilon \in \text{h.a.} \) if \( L_{\varepsilon(0)} = L_\varepsilon \). For each \( \varepsilon \), put \( K_\varepsilon = L_{\varepsilon(0)} \). Thus if \( \varepsilon \in \text{h.a.} \), \( K_\varepsilon \in \text{H.A.} \); conversely, for any \( X \in \text{H.A.} \) there exists an \( \varepsilon \in \text{h.a.} \) with \( X = K_\varepsilon \).

5.11. Lemma. With each recursive function \( \sigma(a, b) \) is associated a recursive function \( \sigma^*(e) \) such that whenever \( e \in \text{h.a.} \) then \( \sigma^*(e) \in \text{h.a.} \) and \( K_{\sigma^*(e)} = K_\varepsilon/\sigma \).

The proof of this is by standard methods of analytic hierarchy theory; cf., for example, Kleene’s [5] or [7].

5.12. Lemma. Suppose \( \theta \) is primitive recursive and that \( \sigma \) is determined by notation recursion (5.9) from \( \theta \) via \( \nu \). Then for any set \( X \), \( \text{Cl}_1^\nu(X) \) implies \( \text{Cl}(X/\sigma) \).

Proof. We must check conditions 5.7(i)-(v) for \( X/\sigma \).

(i) \( 1 \in X/\sigma \) since for any \( a \in X \), \( \sigma(a, 1) = a \in X \).

(ii) Suppose \( d \in X/\sigma \). To show \( 2d \in X/a \), consider any \( a \in X \), \( 1 < a \) and any \( c \leq 2^d \). If \( c < d \) then \( \sigma(a, c) \in X \) by hypothesis. Otherwise \( c = 2^d \). (We can assume \( d \neq 0 \).) But \( \sigma(a, 2^d) = \theta(\sigma(a, d), a) \in X \), by 5.7(vi), since \( \text{Cl}^\nu(X) \) and \( \sigma(a, d) \in X \) and \( 1 < a = \sigma(a, 1) \leq \sigma(a, d) \). Note also \( \sigma(a, d) < \sigma(a, 2^d) \) by 5.7(viii) for \( X, \theta \). Thus if we have \( b < c \leq 2^d \), either \( b < c \leq d \), in which case \( \sigma(a, b) < \sigma(a, c) \) from \( d \in X/\sigma \), or \( b \leq d, c = 2^d \), in which case \( \sigma(a, b) \leq \sigma(a, d) < \sigma(a, 2^d) \), hence \( \sigma(a, b) < \sigma(a, 2^d) \).

(iii) Suppose that for each \( n \), \( [d](n) \in X/\sigma \) and \( [d](n) < [d](n+1) \). To show \( 3 \cdot 5^d \in X/\sigma \), consider any \( a \in X \), \( 1 < a \) and any \( c \leq 3 \cdot 5^d \). If \( c < 3 \cdot 5^d \) then \( c \leq [d](n) \) for some \( n \) and \( \sigma(a, c) \in X \) & \( b \) \( (b < c \rightarrow \sigma(a, b) < \sigma(a, c)) \) by \( [d](n) \in X/\sigma \). Hence we may assume \( c = 3 \cdot 5^d \). We have \( \sigma(a, \sigma(a, d)) = 3 \cdot 5^d \), where \( \nu(a, d) \) \( (n) = \sigma(a, [d](n)) \) for every \( n \). Since each \( [d](n), [d](n+1) \in X/\sigma \) it follows that \( [\nu(a, d)](n) \in X, [\nu(a, d)](n) < [\nu(a, d)](n+1) \) for all \( n \). But \( \text{Cl}(X) \), so \( \sigma(a, 3 \cdot 5^d) = 3 \cdot 5^d(a, d) \in X \). Moreover each \( \sigma(a, [d](n)) < \sigma(a, 3 \cdot 5^d) \).

Thus if \( b < 3 \cdot 5^d, b \leq [d](n) \) for some \( n \), and hence by \( [d](n) \in X/\sigma \) and transitivity of \( \sigma(a, b) \leq \sigma(a, 3 \cdot 5^d) \).

(iv) It is clear that if \( d \in \text{h.a.} \) and \( d_1 < d \) then \( d_1 \in \text{h.a.} \), since \( \text{Cl}(X) \).

(v) is obvious from \( X/\sigma \subseteq X \).

Since \( \sigma \) is not in general associative (not even in the simplest case, \( \oplus \)), we are not able to see that \( X/\sigma \) is closed under \( \sigma \). However, we shall see in 5.14 below that by forming a suitable intersection, we can pass from any \( X \in \text{H.A.} \) such that \( \text{Cl}_1^\nu(X) \) to a subset \( Y \in \text{H.A.} \) such that \( \text{Cl}^\nu(Y) \). First we need the following effectiveness condition for such an intersection.

5.13. Lemma. There is a primitive recursive function \( \iota \) such that whenever
is a recursive function with \( \{ f \} (n) \in h.a. \) for all \( n \) then \( i(f) \in h.a. \) and 
\[
K_{i(f)} = \bigcap K_{\{ f \} (n)} (n = 0, 1, 2, \ldots).
\]

The proof of this is obtained by standard methods [5] for effectively converting the two equivalent conditions for \( a \) to be in the intersection, 
\[
(x)(a) (Ey) T^{a}_{\sigma} ([\{ f \} (x)](0), a, y) \quad \text{and} \quad (x)(Ea)(y) T^{a}_{\sigma} ([\{ f \} (x)](1), a, y)
\]
to the forms \( a \in L_{e_{0}}, a \in L_{e_{1}} \) for suitable \( e_{0}, e_{1} \).

5.14. \textbf{Lemma.} Suppose \( \theta \) is primitive recursive and that \( \sigma \) is defined by notation recursion from \( \theta \) via \( \sigma \). Suppose we have a recursive function \( \tau \) such that for any \( e \), if \( e \in h.a. \) and \( Cl(K_{\sigma}) \) then \( \tau(e) \in h.a. \), \( Cl_{1}(K_{\tau(\sigma)}) \) and \( K_{\tau(\sigma)} \subseteq K_{\sigma} \). Then:

(i) we can find a recursive function \( \pi \) such that for any \( e \in h.a. \) if \( Cl(K_{\sigma}) \) then we have \( \pi(e) \in h.a. \), \( Cl_{1}(K_{\tau(\sigma)}) \) and \( K_{\tau(\sigma)} \subseteq K_{\pi} \);

(ii) \( Cl^{*}(O^{*}) \).

\textbf{Proof.} Define \( \psi(e, 0) = e, \psi(e, n+1) = \sigma^{*}(\tau(\psi(e, n))) \), where \( \sigma^{*} \) is the function of 5.11. Let \( \{ g \} (e, n) = \psi(e, n) \) all \( n \). We define \( \pi(e) = \iota(S^{1}_{0}(g, e)) \). To prove that this satisfies (i), consider any \( e \in h.a. \) such that \( Cl(K_{\sigma}) \). Let \( f = S^{1}_{0}(g, e) \), \( f_{n} = \{ f \} (n) \) for all \( n \). Then we have 
\[
K_{f_{0}} = K_{\sigma}, \quad K_{f_{n+1}} = K_{\sigma^{*}(\tau(\sigma_{n}))} = K_{\tau(\sigma_{n})}/\sigma\quad \text{for all} \ n.
\]

It is seen by induction that \( f_{n} \in h.a. \) for all \( n \); hence \( \pi(e) = \iota(f) \) is h.a. by 5.13. We prove by induction on \( n \) that \( Cl(K_{\sigma}) \). Suppose this for \( n \). Then \( Cl_{1}(K_{\tau(\sigma_{n})}) \) and hence \( Cl(K_{\sigma^{*}(\tau(\sigma_{n}))/\sigma}) \) by 5.12, thus proving it for \( n+1 \).

By 5.13, \( K_{\tau(\sigma)} = K_{\iota(f)} = \bigcap K_{f_{n}} (n = 0, 1, 2, \ldots) \), so that \( Cl(K_{\tau(\sigma)}) \) by 5.8. It remains only to check 5.6(vi), (vii) for \( K_{\tau(f)}, \sigma \). Let \( a, b, c \in K_{\tau(f)}, 1 < a \). Then for each \( n \), we have \( a, b \in K_{f_{n+1}}, \) hence \( \sigma(a, b) \in K_{f_{n+1}} \subseteq K_{f_{n}} \); thus \( \sigma(a, b) \in K_{\tau(f)} \). Already from \( a, b \in K_{f_{1}} \), we can conclude \( b < c \rightarrow \sigma(a, b) < \sigma(a, d) \). Thus \( Cl^{*}(K_{\tau(\sigma)}) \) is proved.

To prove part (ii) of our theorem, we use part (i) and 5.9 to establish the series of inclusions 
\[
O^{*} = \bigcap K_{\sigma}[e \in h.a. \& Cl(K_{\sigma})] \subseteq \bigcap K_{\tau(f)}[f \in h.a. \& Cl^{*}(K_{\tau})] \subseteq \bigcap K_{\tau(\sigma)}[e \in h.a. \& Cl(K_{\sigma})] \subseteq \bigcap K_{\sigma}[e \in h.a. \& Cl(K_{\sigma})] = O^{*},
\]
to conclude by 5.9 that \( Cl^{*}(O^{*}) \).

5.15. \textbf{Theorem.} Let \( \sigma_{1}(a, b) = a \oplus b, \sigma_{2}(a, b) = a \circ b, \sigma_{3}(a, b) = a^{ab} \). Then for \( i = 1, 2, 3, Cl^{*}(O^{*}) \).

\textbf{Proof.} \( \sigma_{1} \) is defined by notation recursion from \( \theta(a, b) = 2^{a} \) via \( \nu_{1}, \sigma_{2} \) is defined by notation recursion from \( \sigma_{1} \) via \( \nu_{2}, \) and \( \sigma_{3} \) is defined by notation recursion from \( \sigma_{2} \) via \( \nu_{3} \). Clearly for any \( X \) such that \( Cl(X) \) we have \( Cl^{*}(X) \). Hence if we take \( \tau(e) = e \), we can find by 5.14 recursive \( \pi_{1} \) such that whenever
120
SOLOMON FEFERMAN [July
e \in \text{h.a. and } \text{Cl}(K_e) \text{ then } \pi_1(e) \in \text{h.a.}, \text{Cl}^{n_1}(K_{\pi_1(e)}) \text{ and } K_{\pi_1(e)} \subseteq K_e, \text{and then also } \text{Cl}^{n_2}(O^*). \text{Noting that } \text{Cl}^{n_1}(K_{\pi_1(e)}), \text{we see that for } a, b \in K_{\pi_1(e)}, \text{if } 1 < a \text{ and } 1 < b \text{ then } a = \sigma_1(a, 1) < \sigma_1(a, b), \text{hence } \text{Cl}^{n_2}(K_{\pi_1(e)}). \text{Hence we can apply 5.14 to } \sigma_1, \pi_1, \sigma_2 \text{ instead of } \theta, \tau, \sigma, \text{to obtain } \pi_2 \text{satisfying 5.14(i) for } \sigma_2 \text{ and then 5.14(ii). Repeating this argument gives us the desired result for } \sigma_3 \text{ as well.}

For any } d \in O^* - O, C'(d) - O \text{ has no least element; for any element of } C'(d) \text{ has one of the forms } 1, 2^b \text{ where } b \in C'(d), \text{or } 3^b \text{ where } (n) \mid \{ [b](n) \in C'(d) \& [b](n) < [b](n+1) \}. \text{Hence we can find an infinite sequence } c_0, c_1, \cdots, c_n, \cdots \text{ such that}

\begin{align*}
& (i) \quad c_0, c_1, \cdots, c_n, \cdots \in O^*, \\
& (ii) \quad \text{for each } n, c_n > c_{n+1} \oplus 1_0.
\end{align*}

In other words we have a subset of order type } \omega^* \text{ (under } <) \text{ in } O. \text{Our construction of a densely ordered subset of } O^* \text{ is based on finding a subset of } O^* \text{ whose ordering is of order type } 2^\omega^*, \text{which is dense. We assume the sequence of } c_n \text{'s is fixed throughout the following.}

5.17. DEFINITION. \text{We denote by } S_\varnothing \text{ the set of all infinite sequences } \xi \text{ such that } \xi_k = 0 \text{ or } \xi_k = 1 \text{ for all } k = 0, 1, 2, \cdots, \text{and such that } \xi_k = 1 \text{ for at least one but only finitely many } k. \text{For } \xi, \eta \in S_\varnothing \text{ we put } \xi \triangleleft \eta \text{ if}

\begin{align*}
& (En)(k)(k < n \rightarrow \xi_k = \eta_k) \& \xi_n < \eta_n).
\end{align*}

For any } a \text{ and any } \xi \in S_\varnothing, \text{if } k_0 < \cdots < k_n \text{ are all the values } k \text{ such that } \xi_k = 1 \text{ we put}

\[
\sum\xi(a) = a^{\varnothing^{k_0}} \oplus (a^{\varnothing^{k_1}} \oplus (\cdots \oplus (a^{\varnothing^{k_{n-1}}} \oplus a^{\varnothing^k}) \cdots))
\]

(or simply } a^{\varnothing^{k_n}} \text{ if } n = 0). \text{Let } \sum*\xi(a) \text{ be the set of all values } \sum\xi(a) \text{ for } \xi \in S_\varnothing.

It is clear that } \triangleleft \text{ is a dense ordering of } S_\varnothing \text{ with no first or last element.}

5.18. LEMMA. \text{For any } a \in O^*, 1 < a, \text{we have } \sum*\xi(a) \subseteq O^*. \text{Moreover, for any } \xi, \eta \in S_\varnothing, \xi \triangleleft \eta \iff \sum\xi(a) < \sum\eta(a).

Proof. \text{The first part of the statement is immediate from 5.15. Consider any } \xi, \eta \in S_\varnothing \text{ with } \xi \triangleleft \eta. \text{Let } n \text{ be the least number with } \xi_n \neq \eta_n, \text{hence } \xi_n = 0, \eta_n = 1. \text{Let } k_0 < \cdots < k_{n-1} \text{ be all } k < n \text{ where } \xi_k = 1, \text{equivalently where } \eta_k = 1. \text{Let } l_0 < \cdots < l_s \text{ be all } l \geq n \text{ where } \eta_l = 1, \text{starting with } l_0 = n. \text{Let } m_0 < \cdots < m_{r-1} \text{ be all } m \geq n \text{ where } \xi_m = 1; \text{hence } m_0 > n. \text{We write } f_i = a^{\varnothing^{l_i}}. \text{We shall write all sums of the form } \sum\xi(a) \text{ without parentheses, with the understanding that association is always to the right. Hence we have}

\[
\begin{align*}
\sum\xi(a) &= f_{k_0} \oplus \cdots \oplus f_{k_{n-1}} \oplus f_{l_1} \oplus \cdots \oplus f_{l_s}, \\
\sum\eta(a) &= f_{k_0} \oplus \cdots \oplus f_{k_{n-1}} \oplus f_{m_0} \oplus \cdots \oplus f_{m_{r-1}}.
\end{align*}
\]

If } r \neq 0, 1 < a < a^{\varnothing^b} < f_{l_1} \oplus \cdots \oplus f_{l_s-1}, \text{since for } 1 < b, 1 < d, \text{we have } b < b^{\varnothing^d} \text{ and } b < b \oplus d. \text{Since also } 1 < f_{l_1} \oplus \cdots \oplus f_{l_s} \text{ by the same argument, we see by
5.15 that $\sum_0(a) < \sum_1(a)$ when $t = 0$. On the other hand, if $t \neq 0$, it suffices by this to prove

\[(2) \quad f_{m_0} \oplus \cdots \oplus f_{m_{t-1}} < f_{i_0} \oplus \cdots \oplus f_{i_t}.
\]

We first show

\[(3) \quad f_{m_0} \oplus \cdots \oplus f_{m_{t-1}} < a^0(c_{m_0} \oplus 1_0).
\]

This is proved by induction on $t$, for $t \geq 1$. For $t = 1$, this simply says $a^0 c_{m_0} < a^0 (c_{m_0} \oplus 1_0)$, which is clear. Suppose for $t - 1 \geq 1$. Then $f_{m_1} \oplus \cdots \oplus f_{m_{t-1}} < a^0 (c_{m_1} \oplus 1_0) < a^0 c_{m_0}$, since $c_{m_1} \oplus 1_0 < c_{m_0}$ by 5.16(ii). Hence $f_{m_0} \oplus \cdots \oplus f_{m_{t-1}} < f_{m_0} a^0 c_{m_0} = a^0 c_{m_0} \oplus a^0 c_{m_0} = a^0 c_{m_0} \circ 1_0 < a^0 c_{m_0} \circ a = a^0 (c_{m_0} \oplus 1_0)$. Thus (3) is proved.

Now since $i_0 \neq m_0$, we have $c_{m_0} \oplus 1_0 < c_{i_0}$ by 5.16(ii), hence $a^0 (c_{m_0} \oplus 1_0) < a^0 c_{i_0} = f_{i_0} \oplus \cdots \oplus f_{i_t}$. Thus (2) is proved, and we have now the proof that $\xi \prec \eta \rightarrow \sum_0(a) < \sum_0(a)$. Since $\prec$ is a simple ordering and $<$ is a partial ordering on $\Omega^*$, the equivalence follows immediately.

5.19. Theorem. There exists a set $\Delta$ of recursive functions densely ordered by $\ll$.

Proof. Pick any $a \in \Omega^*$, $1 < a$. By 5.18, $\sum_0(a)$ is densely ordered without first or last element. By 5.3(ii), $d_1, d_2 \in \sum_0(a)$ & $d_1 < d_2 \rightarrow \rho_{d_1} \ll \rho_{d_2}$. The theorem follows immediately from this.

This result can be obtained for special cases of the majorizing relation very simply. For example, for the function $\chi(a, b) = b$ we can take the set of functions $\theta_r$ for $r$ rational, $0 < r < 1$, where $\theta_r(n) = \lceil r \cdot n \rceil$ (greatest integer function), so that $\theta_r < \theta_s$ whenever $r < s$; similarly for the function $\chi(a, b) = (a + 1) \cdot b$ we take the functions $\theta_r(n) = \lceil r \cdot n \rceil$, so that $n \lceil r \cdot n \rceil < \lfloor s \cdot n \rfloor$ for sufficiently large $n$.

However, we have seen no way of obtaining the result directly for the case of arbitrary recursive $\chi$ with the majorizing relationship. Neither have we seen a way of obtaining 5.19 for the relation $\subset$ without an excursion through nonstandard extensions of hierarchies.

Actually, a somewhat stronger statement than 5.19 can be made, but it is one which is formulated in terms of hierarchies. Let $\| a \|$ be the order type of $C(a)$ for $a \in \Omega^*$. One can prove by induction on $b \in \Omega^*$ that (for any given $a \in \Omega^*$), $(x) [x < a \oplus b \rightarrow x < a \vee (E y) (y < b \& x = a \oplus y)]$. Thus it is seen that $\| a \oplus b \| = \| a \| + \| b \|$. Now in 5.18, we do not have that $\sum_0(a) \oplus a < \sum_0(a)$ for any $\xi \ll \eta$, because of the problem of association. However, it is seen that (by first considering $\xi$ with $\xi \ll \xi \ll \eta$), we have $\| \sum_0(a) \| + \| a \| < \| \sum_0(a) \|$. Thus any two elements $d_1, d_2$ of $\sum_0(a)$ with $d_1 < d_2$ have a distance greater then $\| a \|$ between them. In particular, if we choose $a \in \Omega^* - O$, we have $\| a \| > \omega_1$. Loosely stated, the functions $\rho_d$ associated with $d \in \Omega^*(a)$ are densely ordered by a relation $\ll$ which, when it holds between $\rho_{d_1}, \rho_{d_2}$ implies that there is a sequence of functions $\rho_c$ obtained from a path through $O$ in the subrecursive hierarchy starting with the function $\theta = \rho_{d_1}$, all of which are $\subset \rho_{d_2}$.
