ASYMPTOTIC BEHAVIOR OF THE SOLUTIONS
OF AN nTH ORDER NONHOMOGENEOUS
ORDINARY DIFFERENTIAL EQUATION

BY

THOMAS G. HALLAM

1. Introduction. The asymptotic behavior of the solutions of the nth order
nonhomogeneous differential equation

\[ y^{(n)} + f(t, y, y^{(1)}, \ldots, y^{(n-1)}) = h(t) \]

will be considered. Conditions will be established in order that the solutions of (1.1)
essentially behave asymptotically as those of \( y^{(n)} = h(t) \). The part of the forcing
function \( h(t) \) which is dominant for large values of \( t \) will be called the primary
part of the forcing term. The forcing functions considered here will, generally, have primary part \( t^m e^{bt} \), \( m \) and \( b \) real. Sufficient conditions on \( f \) and \( h \) in order to
guarantee the existence of solutions of (1.1) for large values of \( t \) will be tacitly
assumed.

In [1, §§3.7 and 3.11], Cesari discusses known asymptotic results for equation
(1.1) when the equation is linear and the primary part of \( h(t) \) is a constant. Recent
results on the asymptotic behavior of the solutions of a homogeneous equation
are given in [2]-[4], [6], [7].

§2 of this paper is concerned with integrable forcing terms; that is, \( \int_0^\infty h(t)dt \) is finite. The results of the remainder of the paper are developed for
\( h(t) \) of the form

\[ h(t) = H(t)t^m e^{bt} + R(t), \]

where \( \lim_{t \to \infty} H(t) = A \neq 0 \), and \( R(t) = o(t^m e^{bt}) \) as \( t \) approaches infinity. The main
results give sufficient and in some instances, also necessary conditions for the
solutions of the equation (1.1) to possess an asymptotic behavior of the type
\( y(t)/a(t) \sim k \neq 0 \), where \( a(t) \) is determined by a primitive of \( h(t) \).

The following theorem due to Viswanatham [5] as utilized by Waltman [6], [7]
is useful here.

**Theorem 1.1.** If \( y(t) \leq \rho + \int_T^t f(s, y(s))ds \), where \( f(t, y) \) is continuous and
monotonic increasing in \( y \) in the region \( R \) defined by \( |t - T| < a; |y - \rho| < b \)

---

Presented to the Society, April 9, 1965 under the title Asymptotic behavior of the solutions
of an ordinary nonlinear differential equation; received by the editors July 9, 1965.

(1) Parts of this paper are included in [3], which was directed by Professor W. R. Utz, to
whom the author express his gratitude.

177
where \( a \) and \( b \) are positive real numbers; then \( y(t) \leq z(t) \) where \( z(t) \) is the maximal solution of the differential equation \( z' = f(t, z) \) through \((T, \rho)\) for \( t \geq T \).

An inequality which will be used in the following results is given in

**Lemma 1.1.** Let \( a_i \geq 0, \ b_i \geq 0, \ r_i > 0, \) and \( r = \max_i r_i \) where \( i = 1, 2, \ldots, n. \) If \( b_i > 1 \) for some \( i, \) then

\[
\sum_{i=1}^{n} a_i b_i^{r_i} \leq \left[ \sum_{i=1}^{n} a_i \right] \left[ \sum_{i=1}^{n} b_i \right]^{r}.
\]

2. **Integrable forcing terms.** The differential equation (1.1) is considered subject to the following set of hypotheses.

\[
(f(t, y, y(1), \ldots, y^{(n-1)})) = \sum_{i=0}^{n-1} g_i(t) \left| y^{(i)} \right|^{r_i},
\]

where (2.1.1) \( r_i > 0, \ i = 0, 1, \ldots, n - 1; \)

(2.1.2) \( g_i(t) \) are continuous, \( i = 0, 1, \ldots, n - 1. \)

\[
\int_{t}^{\infty} \left| h(t) \right| \, dt < \infty.
\]

The inequality in (2.1) need hold only for large values of \( t. \)

**Theorem 2.1.** If conditions (2.1) and (2.2) above are satisfied, and \( \int_{t}^{\infty} \left( n - i - 1 \right)! g_i(t) \, dt < \infty, \ i = 0, 1, \ldots, n - 1, \) then there exist solutions \( y(t) \) of (1.1) which have the asymptotic behavior \( \frac{y^{(i)}(t)}{t^{r_i - 1}} \sim a_i \neq 0, \ i = 0, 1, \ldots, n - 1. \)

**Proof.** It will be established that the asymptotic condition is applicable to a given solution \( y(t) \) of (1.1) provided the initial conditions of the solution satisfy a certain inequality.

Integrating (1.1) \( n - k \) times, yields for \( t \geq t_0 \geq 1, \)

\[
y^{(k)}(t) = \theta_0 + \theta_1 t + \cdots + \theta_{n-k-1} t^{n-k-1}
\]

\[
+ \int_{t_0}^{t} \frac{(t-s)^{n-k-1}}{(n-k-1)!} h(s) \, ds
\]

\[
- \int_{t}^{t_0} \frac{(t-s)^{n-k-1}}{(n-k-1)!} f(s, y(s), \ldots, y^{(n-1)}(s)) \, ds.
\]

From this, the inequality

\[
\left| \frac{y^{(k)}(t)}{t^{n-k-1}} \right| \leq A_k + B_k \int_{t_0}^{t} \left| f(s, y(s), \ldots, y^{(n-1)}(s)) \right| \, ds
\]

may be obtained, where
\[ A_k = \left[ \theta_0 + \cdots + \theta_{n-k-1} t_0^{n-k-1} \right] t_0^{k+1-n} + \frac{1}{(n-k-1)!} \int_{t_0}^{\infty} |h(s)| \, ds, \]
and
\[ B_k = \frac{1}{(n-k-1)!}. \]

From (2.1), we have
\[ y^{(k)}(t) = A_k + B_k \int_{t_0}^{t} \sum_{i=0}^{n-1} s^{(n-i-1)r_i} g_i(s) \left| y^{(i)}(s) \right| ds, \]
for all \( k = 0, 1, \ldots, n - 1 \). Thus, using Lemma 1.1,
\[ \sum_{k=0}^{n-1} \left| \frac{y^{(k)}(t)}{t^{n-k-1}} \right| \leq A + B \int_{t_0}^{t} \left[ \sum_{i=0}^{n-1} s^{(n-i-1)r_i} g_i(s) \left| \sum_{i=0}^{n-1} \frac{y^{(i)}(s)}{s^{n-i-1}} \right| \right] ds, \]
where
\[ A = \sum_{k=0}^{n-1} A_k, \]
\[ B = \sum_{k=0}^{n-1} B_k, \]
and
\[ r = \max_{i} r_i. \]

It should be observed that the above inequality does not hold if
\[ \left| \frac{y^{(i)}(t)}{t^{n-i-1}} \right| < 1 \]
for all \( i = 0, 1, \ldots, n - 1 \) and all large values of \( t \). However, if this is the case, \( \sum_{i=0}^{n-1} \left| \frac{y^{(i)}(t)}{t^{n-i-1}} \right| \) is bounded and this is the conclusion which is ultimately desired.

Applying Theorem 1.1 to the above inequality, we obtain as the associated differential equation
\[ z' = B \sum_{i=0}^{n-1} t^{(n-i-1)r_i} g_i(t) z^r. \]
The solutions of (2.5) are given by
\[ z = A \exp \int_{t_0}^{t} B \sum_{i=0}^{n-1} s^{(n-i-1)r_i} g_i(s) \, ds, \quad r = 1; \]
\[ z^{1-r} = A^{1-r} + (1-r) \int_{t_0}^{t} B \sum_{i=0}^{n-1} s^{(n-i-1)r_i} g_i(s) \, ds, \quad r \neq 1. \]

If \( 0 < r \leq 1 \), then \( z(t) \) is bounded independent of initial conditions since the
integrals in (2.6) and (2.7) are convergent. If \( r > 1 \), any solution \( z(t) \) as given in (2.7) will be bounded provided

\[
A^{1-r} > (r-1) \int_{t_0}^{\infty} B \sum_{i=0}^{n-1} s^{(n-i-1)r_i} g_i(s) \, ds.
\]

Since \( z(t_0) = A \), this corresponds to an appropriate choice of initial conditions for the solutions of (1.1). For such a choice of initial conditions, any solution \( y(t) \) of (1.1) may be continued to all \( t \geq t_0 \). This follows from the fact that

\[
\sum_{k=0}^{n-1} \left| \frac{y^{(k)}(t)}{t^{n-k-1}} \right| \leq z(t),
\]

where \( z(t) \) is bounded.

From (2.3), with \( k = n - 1 \), we obtain the equation

\[
y^{(n-1)}(t) = c_{n-1} + \int_{t_0}^{t} h(s) \, ds - \int_{t_0}^{t} f(s, y(s), \ldots, y^{(n-1)}(s)) \, ds.
\]

Noting that \( \int_{t_0}^{\infty} h(s) \, ds \) converges and that the integral \( \int_{t_0}^{\infty} \sum_{l=0}^{n-1} s^{(n-i-1)r_l} g_l(s) \, ds \) is majorized by the integral \( \int_{t_0}^{\infty} \sum_{l=0}^{n-1} s^{(n-i-1)r_l} g_l(s) \, ds \), it is clear that \( \lim_{t \to \infty} y^{(n-1)}(t) \) is finite, say \( a_{n-1} \). Therefore, by L'Hospital's Rule, \( \lim_{t \to \infty} \frac{y^{(i)}(t)}{t^{n-i-1}} \) exists for all \( i = 0, 1, \ldots, n-1 \). It remains to show these limits may be chosen different from zero. Clearly, it suffices to show \( a_{n-1} \) may be chosen distinct from zero.

Select \( A > 0 \) and \( t_0 \) sufficiently large such that

\[
A^{1-r} > (r-1) \int_{t_0}^{\infty} B \sum_{i=0}^{n-1} s^{(n-i-1)r_i} g_i(s) \, ds.
\]

This condition on \( A \) guarantees that \( \sum_{l=0}^{n-1} \left| \frac{y^{(i)}(t)}{t^{n-i-1}} \right| \) is bounded for all \( r \). Choose \( t_1 \) so that for \( 0 < \varepsilon < A \),

\[
\left| \int_{t_1}^{\infty} h(s) \, ds - \int_{t_1}^{\infty} f(s, y(s), \ldots, y^{(n-1)}(s)) \, ds \right| < \varepsilon.
\]

The solution \( y(t) \) of (1.1) having the initial conditions

\[
y(t_1) = y^{(1)}(t_1) = \ldots = y^{(n-2)}(t_1) = 0, \quad y^{(n-1)}(t_1) = A,
\]

has the desired type of asymptotic behavior.

**Remark 2.1.** For \( 0 < r \leq 1 \), the proof as given in the above theorem shows all solutions \( y(t) \) of (1.1) have the asymptotic behavior \( y^{(i)}(t) / t^{n-i-1} \sim a_i \). This follows from the fact that \( z(t) \), a solution of (2.5), is always bounded independent of initial conditions.

In the next theorem, a special case of equation (1.1) will be considered. The differential equation which will be considered is
(2.8) \[ y^{(n)} + \sum_{i=0}^{n-1} g_i(t)[y^{(i)}(t)]' = h(t). \]

Conditions (2.1.1) and (2.1.2) will still be imposed. Further restrictions which will be imposed are

(2.9) \[ r_i = u_i/w_i \text{ where } u_i \text{ and } w_i \text{ are odd integers, } \quad i = 0, 1, \ldots, n - 1. \]

(2.10) If \( g_i(t) \) is not identically zero, then \( \lim_{t \to \infty} t^{p_i} g_i(t) = c_i \neq 0 \) for some \( p_i \) and all \( i = 0, 1, \ldots, n - 1 \). Furthermore, it is required that the signs of the \( c_i \) agree for all \( i = 0, 1, \ldots, n - 1 \) where \( g_i(t) \) is not identically zero.

**Theorem 2.2.** Let conditions (2.1.1), (2.1.2), (2.9), and (2.10) be satisfied. A necessary and sufficient condition for some solution \( y(t) \) of (2.8) to have the asymptotic behavior \( y^{(i)}(t)/t^{n-i-1} \sim c_i \neq 0 \) is that \( p_i > r_i(n-i-1) + 1 \) for all \( i = 0, 1, \ldots, n - 1 \) where \( g_i(t) \) is not identically zero.

**Proof.** Since (2.8) is a special case of the equation (1.1) of Theorem 2.1, the sufficiency of the condition follows provided \( \int_0^\infty t^{\nu-i-1} r_i g_i(t) \ dt < \infty \). This follows immediately from (2.10).

In order to prove the converse, suppose some solution \( y(t) \) of (2.8) has the asymptotic behavior \( y^{(i)}(t)/t^{n-i-1} \sim c_i \neq 0 \), and for some \( j \) where \( g_j(t) \) is not identically zero, \( p_j \leq r_j(n-j-1) + 1 \). By hypothesis, \( r_i \) is odd, \( i = 0, 1, \ldots, n - 1 \); thus if \( y(t) \) is a solution of (2.8), \( -y(t) \) satisfies equation (2.8) with \( h(t) \) replaced by \( hy(t) = -h(t) \). Since \( h(t) \) is integrable if and only if \( n(r) \) is integrable, the nature of the forcing term is similar with respect to the property of being integrable. Thus, we may assume that \( y(t) \) is eventually positive and consequently \( a_i > 0, \ i = 0, 1, \ldots, n - 1 \).

Select constants \( A \) and \( C \) in the following manner: \( 0 < A < a_i \) for all \( i = 0, 1, \ldots, n - 1 \); \( 0 < C < |c_i| \) for all \( i = 0, 1, \ldots, n - 1 \) such that \( g_i(t) \) is not identically zero. Choose \( \varepsilon > 0 \) and satisfying the inequalities \( 0 < A < a_i - \varepsilon \) and \( 0 < C < |c_i| - \varepsilon \) with \( i \) as above. There exist \( T_{a_i, \varepsilon} \) and \( T_{c_i, \varepsilon} \) such that if \( t \geq T_{a_i, \varepsilon} \), then

(2.11) \[ y(t)/t^{n-i-1} > a_i - \varepsilon > A, \quad i = 0, 1, \ldots, n - 1; \]

and if \( t \geq T_{c_i, \varepsilon} \) then

(2.12) \[ t^{p_i} |g_i(t)| > |c_i| - \varepsilon > C \]

for all \( i = 0, 1, \ldots, n - 1 \) where \( g_i(t) \) is not identically zero.

From (2.8), for \( t \geq T = \max (T_{a_i, \varepsilon}, T_{c_i, \varepsilon}) \), consider

(2.13) \[ |y^{(n)} + \sum_{k} g_k(t)[y^{(k)}(t)]'| = \left| \sum_{j} g_j(t)[y^{(j)}(t)]' \right|. \]
The $k$-index set consists of those $k$ whose associated $p_k$ have the property that
$p_k > r_k(n - k - 1) + 1$. The $j$-index set contains those $j$ whose associated $p_j$
satisfy the inequality $p_j \leq r_j(n - j - 1) + 1$. By assumption, the $j$-index set is
nonempty so that the right side of (2.13) is different from zero. In the $\Sigma_j$ sum,
the $g_j(t)$ may be assumed positive since they are all positive or all negative.
Therefore,

$$
\left| \sum_j g_j(t) \left[ y^{(j)}(t) \right]' \right| = \sum_j t^p g_j(t) \left[ \frac{y^{(j)}(t)}{t^{n-j-1}} \right]' e^{r_j(n-j-1)-p_j} > CA^r e^{(n-q-1)-p_q} > 0,
$$

where $q$ is in the $j$-index set.

Using the above inequality in (2.13) yields the inequality

$$
y^{(n)} + \sum_k g_k(t) \left[ y^{(k)}(t) \right]^k - h(t) > 0.
$$

Thus, $y^{(n)} + \sum_k g_k(t) \left[ y^{(k)}(t) \right]^k - h(t)$ is of one sign for all large $t$. Suppose it is
positive for $t \geq T$, then

$$(2.14) \quad y^{(n)} + \sum_k g_k(t) \left[ y^{(k)}(t) \right]^k - h(t) > CA^r e^{(n-q-1)-p_q}.
$$

Integration of (2.14) gives the inequality

$$
y^{(n-1)}(t) - y^{(n-1)}(T) + \sum_k \int_T^t g_k(s) \left[ y^{(k)}(s) \right]^k ds - \int_T^t h(s) ds \geq CA^r \int_T^t s^{e(n-q-1)-p_q} ds.
$$

(2.15)

For any $k$, $r_k(n - k - 1) - p_k < -1$, thus

$$
\int_T^\infty s^{r_k} g_k(s) \left[ \frac{y^{(k)}(s)}{s^{n-k-1}} \right] s^{r_k} e^{r_k(n-k-1)-p_k} ds < M \int_T^\infty s^{r_e(n-k-1)-p_k} ds < \infty.
$$

Therefore, the integrals on the left in (2.15) are finite as $t$ approaches infinity.

Now, if $r_q(n - q - 1) - p_q > -1$,

$$
\int_T^t s^{r_q(n-q-1)-p} ds
$$

(2.16)

$$
= \left[ r_q(n - q - 1) - p_q + 1 \right]^{-1} \left[ e^{r_q(n-q-1)-p} + 1 - T^{r_q(n-q-1)-p+1} \right];
$$

if $r_q(n - q - 1) - p_q = -1$,
Substitution of (2.16) or (2.17), the choice determined by the value of \( r \), into (2.15) leads to \( \lim_{t \to \infty} y^{(n-1)}(t) = \infty \). However, this contradicts the hypothesis that \( \lim_{t \to \infty} y^{(n-1)}(t) = a_n \).

If the expression \( y^{(n)} + \sum_k g_k(t) y^{(k)}(t) - h(t) \) is negative for \( t \geq T \), an inequality similar to (2.14) is obtained. Proceeding with an analogous argument as above leads to a similar contradiction and the theorem is proved.

**Remark 2.2.** A simple example shows that the theorem cannot be proved, even in the linear case, when the signs of the \( c_i \) are different. The differential equation

\[
y'' - y' + t^{-1}y = 0
\]

has \( y(t) = t \) as a solution; however, the condition in the theorem is violated.

3. **Forcing terms with primary part \( t^m, m > -1 \).** In this section, differential equation (1.1) is considered with condition (2.1) imposed. Further hypotheses which will be required are

\[
(3.1) \quad \text{If } g_i(t) \text{ is not identically zero then } \lim_{t \to \infty} t^{p_i} g_i(t) = c_i \neq 0 \text{ for some } p_i.
\]

\[
(3.2) \quad h(t) = h_m(t) t^m + R_m(t)
\]

where (3.2.1) \( m > -1 \);

(3.2.2) \( h(t) \) is continuous for \( t \geq t_0 \);

(3.2.3) \( \lim_{t \to \infty} h_m(t) = b_m \neq 0 \);

(3.2.4) \( R_m(t) = o(t^m) \) as \( t \to \infty \).

Again, the inequality in (2.1) need hold only for all large values of \( t \).

**Theorem 3.1.** If conditions (2.1), (3.1), and (3.2) are satisfied; and for each \( i = 0,1,\ldots,n-1, r_i \leq 1, p_i > r_i(m + n - i) - m \), then all solutions \( y(t) \) of (1.1) have the asymptotic behavior \( y^{(i)}(t) t^{m+n-i} \sim a_i \neq 0, i = 0,1,\ldots,n-1 \). If \( r_i > 1 \) for some \( i, i = 0,1,\ldots,n-1 \), and the above conditions hold, then there exist solutions \( y(t) \) of (1.1) which have the asymptotic behavior \( y^{(i)}(t) t^{m+n-i} \sim a_i \neq 0 \), for all \( i = 0,1,\ldots,n-1 \).

**Proof.** From (2.3), dividing by \( t^{m+n-k} \), gives the equation

\[
\frac{y^{(k)}(t)}{g^{m+n-k}} = \left[ \theta_0 + \theta_1 t + \cdots + \theta_{n-k-1} t^{n-k-1} \right] t^{-m-n}
\]

\[
+ \int_{t_0}^{t} \frac{(t-s)^{n-k-1}}{(n-k-1)!} h(s) \, ds
\]

\[
- \int_{t_0}^{t} \frac{(t-s)^{n-k-1}}{(n-k-1)!} f(s, y(s), \cdots, y^{(n-1)}(s)) \, ds.
\]
If \( r_i \leq 1 \) for all \( i = 0, 1, \ldots, n - 1 \), then it will be shown that \( y^{(k)}(t)/t^{m+n-k} \) is bounded. If \( r_i > 1 \) for some \( i \), it will be necessary to select proper initial conditions for \( y(t) \) in order to show the existence of a bound for \( y^{(k)}(t)/t^{m+n-k} \).

The first term on the right in (3.3) is bounded since \( m > -1 \). L'Hospital's Rule for evaluating indeterminant forms may be applied \( n - k \) times to the second term in (3.3); this yields the result

\[
\lim_{t \to \infty} \int_{t_0}^{t} \frac{(t-s)^{n-k-1}}{(n-k-1)!} h(s) \, ds / t^{m+n-k} = \frac{b_m}{(m+n-k) \cdots (m+1)} \neq 0.
\]

Thus, the second term on the right in (3.3) is bounded for all large \( t \). Let \( C_k > 0 \) be an upper bound on the absolute value of these two terms in (3.3); suppose this bound is valid for \( t \geq T_k \). Note that the \( C_k \) depend upon the initial conditions of the particular solution in question. For \( \varepsilon > 0 \), by virtue of (3.1), there exists an \( L_k \) such that if \( t \geq L_k \) then \( t^{p_k} y_k(t) < c_k + \varepsilon = d_k \). From (3.3), with \( T = \max_k (t_0, T_k, L_k) \), we have

\[
|y^{(k)}(t)| / t^{m+n-k} \leq C_k + B_k \int_T^t \sum_{i=0}^{n-1} s^r_{i(m+n-i)-p_i-m-1} \left| \frac{y^{(i)}(s)}{s^m+n-i} \right| \, ds,
\]

where \( B_k = \sum_{i=0}^{n-1} d_i / (n-k-1)! \), \( k = 0, 1, \ldots, n-1 \). Therefore,

\[
\sum_{k=0}^{n-1} \left| \frac{y^{(k)}(t)}{t^{m+n-k}} \right| \leq C + B \int_T^t \left[ \sum_{i=0}^{n-1} s^r_{i(m+n-i)-p_i-m-1} \right] \left[ \sum_{i=0}^{n-1} \left| \frac{y^{(i)}(s)}{s^{m+n-i}} \right| \right] \, ds,
\]

with

\[
C = \sum_{k=0}^{n-1} C_k,
\]

\[
B = \sum_{k=0}^{n-1} B_k,
\]

and

\[
r = \max_i r_i.
\]

Again, the above inequality need not hold if the inequality \( |y^{(i)}(t)/t^{m+n-i}| < 1 \) for all \( i = 0, 1, \ldots, n - 1 \); however, the objective is to show that

\[
\sum_{i=0}^{n-1} \left| \frac{y^{(i)}(t)}{t^{m+n-i}} \right|
\]

is bounded and \( y(t) \) which possess the above property clearly satisfy this condition.

The differential equation associated with the above integral inequality (see Theorem 1.1) is

\[
z' = B \sum_{i=0}^{n-1} t^{p_i(m+n-i)-m-1-p_i} z^r.
\]

The solutions of the above differential equation are given by
\[ z(t) = C \exp \int_T^t B \sum_{i=0}^{n-1} s^{r(m+n-i)-m-1-p_i} ds, \quad r = 1; \tag{3.4} \]

\[ z(t)^{1-r} = C^{1-r} + (1 - r) \int_T^t B \sum_{i=0}^{n-1} s^{r(m+n-i)-m-1-p_i} ds, \quad r \neq 1. \tag{3.5} \]

If \( r \leq 1 \), then all solutions \( z(t) \) as given in (3.4) or (3.5) are bounded since the integrals in both expressions are convergent as \( t \) approaches infinity. If \( r > 1 \), in order to determine boundedness of the solutions as given by (3.5), \( C \) and \( t_0 \) must be properly chosen in order to guarantee the boundedness of \( z(t) \). For such \( z(t) \), it follows from Theorem 1.1 that

\[ \sum_{i=0}^{n-1} \left| y^{(i)}(t) / t^{m+n-i} \right| \leq z(t) \leq D. \]

It remains to show that \( \lim_{t \to \infty} y^{(k)}(t) / t^{m+n-k} = a_k \neq 0 \) for all solutions \( y(t) \) of (1.1) which satisfy the previous inequality. As remarked before, \( m > -1 \) gives

\[ \lim_{t \to \infty} \left[ \theta_0 + \theta_1 t + \cdots + \theta_{n-1} t^{n-1} \right] / t^{m+n} = 0; \tag{3.6} \]

and

\[ \lim_{t \to \infty} \int_T^t \frac{(t-s)^{n-k-1}}{(n-k-1)!} h(s) ds / t^{m+n-k} = \frac{b_m}{(m+n-k) \cdots (m+1)} \neq 0. \tag{3.7} \]

To evaluate the limit of the third term in (3.3), consider

\[ \left| \int_T^t \frac{(t-s)^{n-k-1}}{(n-k-1)!} f(s, y(s), \ldots, y^{(n-1)}(s)) ds \right| \]

\[ \leq \frac{t^{m-1}}{(n-k-1)!} \int_T^t \sum_{i=0}^{n-1} s^{p_i} g_i(s) \left| \frac{y^{(i)}(s)}{s^{m+n-i}} \right| s^{r(m+n-i)-p_i} ds \]

\[ \leq \sum_k d_k D_k^k t^{m-n-1} \left[ \frac{r_k(m+n-k)-p_k+1 - T_k(m+n-k)-p_k+1}{r_k(m+n-k)-p_k+1} \right] \]

\[ + \sum_j d_j D_j^j t^{m-n-1} [\ln t - \ln T] , \]

where the \( \Sigma_k \) sum has as an index set those \( k \) such that \( p_k \neq r_k(m+n-k)+1 \); and the \( \Sigma_j \) summation is summed over those \( j \) where \( p_j = r_j(m+n-j)+1 \). Using the hypotheses that \( p_k > r_k(m+n-k)-m \) in the \( \Sigma_k \) term and \( m > -1 \) in the \( \Sigma_j \) sum, we obtain

\[ \lim_{t \to \infty} t^{k-n} \int_T^t \frac{(t-s)^{n-k-1}}{(n-k-1)!} f(s, y(s), \ldots, y^{(n-1)}(s)) ds = 0. \tag{3.8} \]

Combining the results of (3.6), (3.7), and (3.8) in (3.3), yields

\[ \lim_{t \to \infty} y^{(k)}(t) / t^{m+n-k} = a_k \neq 0. \]
This concludes the proof of the theorem.

In the following theorem a partial converse of Theorem 3.1 is given for the differential equation (2.8).

**Theorem 3.2.** Let the hypotheses (2.1.1), (2.1.2), (2.9), (2.10), and (3.2) be satisfied. If any solution \( y(t) \) of (2.8) has the asymptotic behavior

\[
y^{(i)}(t)/t^{m+n-i} \sim a_i \neq 0, \quad i = 0, 1, \ldots, n - 1,
\]

then \( p_i \geq r_i(m + n - i) - m \) for all \( i = 0, 1, \ldots, n - 1 \).

**Proof.** Suppose \( p_j < r_j(m + n - j) - m \) for some \( j \) where \( j = 0, 1, \ldots, n - 1 \). Write (2.8) in the form

\[
y^{(n)}(t) + \sum_k g_k(t) y^{(k)}(t) y(t) - h(t) = - \sum_j g_j(t) y^{(j)}(t) y(t).
\]

In (3.9), the \( \sum_k (\sum_j) \) sum ranges over those \( k (j) \) whose associated \( p_k (p_j) \) satisfy the inequality \( p_k \geq r_k(m + n - k) - m \) \( (p_j < r_j(m + n - j) - m) \). By hypothesis, the \( j \)-index set is nonempty.

Dividing (3.9) by \( t^n \) and taking the limit as \( t \) approaches infinity yields the equation

\[
\lim_{t \to \infty} y^{(n)}(t)/t^n + \sum_k c_k a_k p_k - b_m = - \sum_j c_j a_j \lim_{t \to \infty} \frac{r_j(m + n - j) - m - p_j}{t^{r_j(m + n - j) - m - p_j}}.
\]

where

\[
p_k = \begin{cases} 
0 & \text{if } p_k > r_k(m + n - k) - m, \\
1 & \text{if } p_k = r_k(m + n - k) - m.
\end{cases}
\]

Since \( p_j < r_j(m + n - j) - m \), and \( c_j a_j \) are all of the same sign, \( \lim_{t \to \infty} y^{(n)}(t)/t^n = \pm \infty \). This contradicts

\[
a_{n-1} = \lim_{t \to \infty} y^{(n-1)}(t)/t^{n+1} = \lim_{t \to \infty} y^{(n)}(t)/(m + 1)t^n.
\]

**Remark 3.1.** The previous theorem may be improved slightly. Suppose for some \( j \)'s, \( p_j = r_j(m + n - j) - m \), where \( j \) is in the set \( 0, 1, \ldots, n - 1 \). From the differential equation (2.8),

\[
\frac{y^{(n)}}{t^n} = \frac{h(t)}{t^n} - \sum_k t^{p_k} g_k(t) \left[ \frac{y^{(k)}(t)}{t^{m+n-k}} \right]^{r_k} t^{r_k(m+n-k)-p_k-m} - \sum_j t^{p_j} g_j(t) \left[ \frac{y^{(j)}(t)}{t^{m+n-j}} \right]^{r_j} t^{r_j(m+n-j)-p_j-m},
\]

where the \( k \)-index set consists of those \( k \) such that \( p_k > r_k(m + n - k) - m \) and the \( j \)-index set consists of those \( j \) such that \( p_j = r_j(m + n - j) - m \). Therefore,
\[ \lim_{t \to \infty} y^{(n)}/t^m = b_m - \sum_j c_j a^j, \]

and necessarily
\[ a_{n-1} = \lim_{t \to \infty} y^{(n-1)}/t^{m+1} = \left( b_m - \sum_j c_j a^j \right)/(m + 1). \]

But,
\[ a_0 = \lim_{t \to \infty} y(t)/t^{m+n} = \lim_{t \to \infty} y^{(k)}/(m + n) \cdots (m + n - k + 1)t^{m+n-k} \]

therefore,
\[ a_k = (m + n) \cdots (m + n - k + 1)a_0, \quad k = 0, 1, \ldots, n - 1. \]

Using this result in (3.10), we obtain the equation
\[ (m + n)(m + n - 1) \cdots (m + 1)^2 a_0 = b_m - \sum_j c_j[(m + n) \cdots (m + n - j + 1)a_0]^j. \]

Equation (3.11) improves Theorem 3.2 for the case where \( p_i = r_i(m + n - i) - m \) for some \( i, i = 0, 1, \ldots, n - 1 \), by placing an additional restriction on \( a_0 \). For if \( a_0 \) is not a root of (3.11), then a contradiction is obtained.

**Remark 3.2.** The example given in this remark shows that Remark 3.1 yields the best possible result subject to our hypotheses. Consider the differential equation
\[ y^{(n)} - c t^m y = b_m t^m, \]

where \( c \neq 0 \) and \( b_m \neq 0 \) are determined by the equation
\[ (m + n) \cdots (m + 1) - c = b_m. \]

Note \( y = t^{m+n} \) is a solution of (3.12) having the desired asymptotic property.

**Remark 3.3.** An example which shows that the hypothesis concerning the signs of the \( c_i \) is necessary is
\[ y'' - y' + 3t^{-1}y = 6t. \]

\( y = t^3 \) is a solution having the asymptotic property \( y(t)/t^3 \sim 1 \); however, \( p_i \geq r_i(m + n - i) - m \) is false for \( i = 0, 1 \).

**Remark 3.4.** The motivation for the previous theorems is due to the reasoning that if the coefficients of \( y, y', \ldots, y^{(n-1)} \), approach zero sufficiently fast then the solutions of (2.1) should behave like the solutions of the equation \( y'' = h(t) \). It is interesting to observe that if the nonlinearity, as determined by the \( r_i \)'s, is sufficiently small it is actually possible for the coefficients to have limit infinity rather than zero.

**Remark 3.5.** Proceeding under the hypotheses (2.1.1), (2.1.2), (2.9), (2.10), and (3.2), we investigate other possible types of asymptotic behavior of solutions.
of (2.8). The kind of behavior discussed here is $y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0$, with $\rho < m + n$, $\rho \neq 0, 1, \cdots, n - 1$, $i = 0, 1, \cdots, n - 1$. First, we establish the following result.

If $p_i \leq r_i(\rho - i) - \rho + n$ then no solution $y(t)$ of (2.8) has the behavior $y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0$.

Since $\rho \neq 0, 1, \cdots, n - 1$, then

$$a_{n-1} = \lim_{t \to \infty} y^{(n-1)}(t)/t^{\rho-n+1} = \lim_{t \to \infty} y^{(n)}(t)/(\rho - n + 1)t^{\rho-n}$$

provided the latter limit exists. Suppose $y(t)$ is any solution of (2.8) which has the asymptotic property $y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0$. From (2.8),

$$y^{(n)}(t)/t^{\rho-n} = \frac{h(t)}{t^{\rho-n}} - \sum_{i=0}^{n-1} t^\rho g_i(t) \left[ \frac{y^{(i)}(t)}{t^{\rho-i}} \right] t^{i(\rho-i) - p_i - \rho + n}.$$ 

Therefore, $\lim_{t \to \infty} y^{(n)}(t)/t^{\rho-n} = \pm \infty$. This is a contradiction and thus, if any solution $y(t)$ of (2.8) has the asymptotic property $y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0$, then for all $i = 0, 1, \cdots, n - 1$, $p_i > r_i(\rho - i) - \rho + n$.

Consider (2.8) where the differential equation is linear, that is, $r_i = 1$ for all $i = 0, 1, \cdots, n - 1$. Suppose some solution $y(t)$ of (2.8) has the asymptotic behavior $y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0$, $\rho < m + n$, $i = 0, 1, \cdots, n - 1$. From Theorem 3.1, $p_i$ satisfies the inequality

$$p_i \leq n - i, \quad i = 0, 1, \cdots, n - 1.$$ 

From the above result,

$$p_i > n - i, \quad i = 0, 1, \cdots, n - 1.$$ 

Since these two statements are incompatible we have shown that for no $p_i$ can the linear equation possess solutions which have the asymptotic behavior

$$y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0,$$

where $\rho < m + n$.

In the next remark investigation of the asymptotic behavior of solutions of (2.8), under the hypotheses of Remark 3.5, is continued. In particular, the behavior

$$y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0, \quad \rho = 0, 1, \cdots, n - 1, \quad i = 0, 1, \cdots, n - 1,$$

is discussed.

**Remark 3.6.** If some solution $y(t)$ of (2.8) has the asymptotic behavior $y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0$ then for all $i = 0, 1, \cdots, n - 1$, $p_i \geq r_i(\rho - i) - m$.

**Proof.** From the differential equation (2.8),

$$\frac{y^{(n)}(t)}{t^{\rho-n}} = \frac{h(t)}{t^{\rho-n}} - \sum_{i=0}^{n-1} t^\rho g_i(t) \left[ \frac{y^{(i)}(t)}{t^{\rho-i}} \right] t^{i(\rho-i) - p_i - \rho + m}.$$ 

Taking the limit as $t$ approaches infinity yields the equation
\[
\lim_{t \to \infty} \frac{y^{(n)}(t)}{t^m} = b_m - \sum_{i=0}^{n-1} c_i a_i^{r_i} \lim_{t \to \infty} t^{r_i(r_i-i)-p_i-m}.
\]

If \( p_j < r_j(p-j) - m \) for some \( j \), \( \lim_{t \to \infty} t^{r_j(p-j)-p_j-m} = \infty \). This implies \( \lim_{t \to \infty} y^{(n)}(t)/t^m = \pm \infty \), which yields a contradiction as previously observed. This completes the proof of the remark.

We continue with the investigation of asymptotic behavior of the form \( y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0; \rho, i = 0, 1, \ldots, n - 1 \). Suppose \( y(t) \) is a solution of (2.8) having the above given asymptotic behavior and \( p_i \geq r_i(p - i) - m, \ i = 0, 1, \ldots, n - 1 \).

From (2.8), we obtain

\[
y^{(n)} + \sum_j t^{p_j} g_j(t) \left[ \frac{y^{(j)}(t)}{t^{\rho-j}} \right]^{r_j} t^{r_j(p-j)-p_j-m} = h(t)
\]

where the \( j \)-index (\( k \)-index) set consists of those \( j \) (\( k \)) whose associated \( p_j > r_j(p-j) - m \) (\( p_k = r_k(p - k) - m \)). Taking the limit as \( t \) approaches infinity, yields the equation

\[
\lim_{t \to \infty} \frac{y^{(n)}(t)}{t^m} = b_m - \sum_k c_k a_k^{r_k} = 0.
\]

Therefore, it is necessary that the equation

\[
b_m - \sum_k c_k a_k^{r_k} = 0
\]

be satisfied in order that \( y^{(i)}(t)/t^{\rho-i} \sim a_i \neq 0 \).

For a special case of equation (2.8),

\( (3.13) \ y^{(n)} + g(t)y^r = h(t), \)

the above remark may be improved. We assume that \( \lim_{t \to \infty} t^p g(y) = c \neq 0 \) for some \( p \); \( h(t) \) is as given by (3.2); \( r > 0 \) and odd in the sense previously given.

**Remark 3.7.** If some solution \( y(t) \) of (3.13) has the asymptotic behavior \( y(t)/t^\rho \sim a \neq 0, \ \rho = 0, 1, \ldots, n - 1 \), then \( p = p(r - m) \). When \( p = p(r - m) \) the asymptotic behavior can occur only if \( b_m - ca^r = 0 \).

**Proof.** By Remark 3.6, \( p \geq p(r - m) \). If \( p > p(r - m) \), then \( \lim_{t \to \infty} t^{p(r-m)-p} = 0 \). As in the previous remark,

\[
0 = \lim_{t \to \infty} \frac{y^{(n)}(t)}{t^m} = b_m \neq 0.
\]

Again, we have reached a contradiction and the first statement of the remark is proved.

Suppose that \( p = p(r - m) \) and \( b_m - ca^r \neq 0 \). From the differential equation (3.13),

\[
0 = \lim_{t \to \infty} \frac{y^{(n)}(t)}{t^m} = b_m - ca^r \neq 0.
\]
This completes the proof of the remark.

4. Forcing terms with primary part \( t^{-1} \). Asymptotic properties of the solutions of (1.1) with the forcing term essentially behaving like \( t^{-1} \) will be considered in this section. The conditions (2.1) and (3.1) are assumed throughout the section. The explicit hypothesis concerning the forcing term \( h(t) \) is given by

\[
h(t) = h_{-1}(t)t^{-1} + R_{-1}(t),
\]

where (4.1.1) \( h(t) \) is continuous for \( t \geq t_0 \);

(4.1.2) \( \lim_{t \to \infty} h_{-1}(t) = b_{-1} \neq 0 \);

(4.1.3) \( R_{-1}(t) = o(t^{-1}) \) as \( t \) approaches infinity.

**Theorem 4.1** If (2.1), (3.1), and (4.1) are valid, \( \int_0^t \! r^{(a-1)-p_i}(\ln t)^{r-1} \, dt < \infty \), and \( r_i \leq 1 \) for \( i = 0, 1, \ldots, n-1 \), then all solutions of (1.1) have the asymptotic behavior

\[
y^{(i)}(t)/t^{n-i-1}\ln t \sim a_i \neq 0, \quad i = 0, 1, \ldots, n-1.
\]

If \( r_i > 1 \) for some \( i \) and the above conditions hold, then there exist solutions \( y(t) \) of (1.1) which have the asymptotic behavior \( y^{(i)}(t)/t^{n-i-1}\ln t \sim a_i \neq 0 \).

**Proof.** Consider (2.3) divided by \( t^{n-k-1}\ln t \),

\[
\frac{y^{(k)}(t)}{t^{n-k-1}\ln t} = \left[ \theta_0 + \theta_1 t + \cdots + \theta_{n-k-1} t^{n-k-1} \right] \left[ t^{n-k-1}\ln t \right]^{-1} \\
+ \left[ t^{n-k-1}\ln t \right]^{-1} \int_{t_0}^t \frac{(t-s)^{n-k-1}}{(n-k-1)!} h(s) \, ds \\
- \left[ t^{n-k-1}\ln t \right]^{-1} \int_{t_0}^t \frac{(t-s)^{n-k-1}}{(n-k-1)!} f(s, y(s), \ldots, y^{(n-1)}(s)) \, ds.
\]

Clearly, the first term in (4.2) is bounded for all large \( t \). Application of L'Hospital's Rule to the second term on the right in (4.2) gives the equation

\[
\lim_{t \to \infty} \left[ t^{n-k-1}\ln t \right]^{-1} \int_{t_0}^t \frac{(t-s)^{n-k-1}}{(n-k-1)!} h(s) \, ds = -\frac{b_{-1}}{(n-k-1)!}.
\]

Proceeding as in the proof of Theorem 3.1, let \( C_k > 0 \) be an upper bound on the absolute value of the first two terms valid for \( t \geq T_k \). For \( \epsilon > 0 \), there exists an \( L_k \) such that if \( t \geq L_k \) then \( s_{g_k}(t) < c_k + \epsilon = d_k \). From (4.2), we obtain

\[
\sum_{k=0}^{n-1} \left| \frac{y^{(k)}(t)}{t^{n-k-1}\ln t} \right| \\
\leq C + B \int_{T}^{t} \left( \sum_{i=0}^{n-1} s^i r^{(n-i-1)-p_i}(\ln s)^{r-1} \right) \left( \sum_{i=0}^{n-1} \frac{y^{(i)}(s)}{s^{n-i-1}\ln s} \right)^r,
\]

where
The differential equation associated with the above integral inequality is

\[ z' = B \sum_{i=0}^{n-1} t^{i(n-i-1)-r_i'(\ln t)^{r_i-1}z}. \]

The remainder of the argument proceeds as in Theorem 3.1, and for this reason will be omitted.

**Theorem 4.2.** Let conditions (2.1.1), (2.1.2), (2.9), (2.10), and (4.1) be satisfied. A necessary and sufficient condition for some solution of (2.8) to have the asymptotic behavior \( y^{(i)}(t)/t^{n-i-1}\ln t \sim a_i, \quad i = 0, 1, \ldots, n - 1, \) is that

\[ p_i > r_i(n - i - 1) + 1, \quad i = 0, 1, \ldots, n - 1. \]

**Proof.** In order to show the condition is sufficient, let \( p_i = r_i(n - i - 1) + 1 + \varepsilon_i, \) where \( \varepsilon_i \) is positive for all \( i = 0, 1, \ldots, n - 1. \) Consider

\[ \int_{t_0}^{\infty} t^{r_i(n-i-1)-p_i'(\ln t)^{r_i-1}} dt < \int_{t_0}^{\infty} t^{r_i(n-i-1)-p_i-\varepsilon_i/2} dt < \infty. \]

By Theorem 4.1, there exists a solution \( y(t) \) of (2.8) such that

\[ y^{(i)}(t)/t^{n-i-1}\ln t \sim a_i \neq 0. \]

In order to prove the necessity of the condition, consider

\[ ty^{(n)} + \sum_k g_k(t) y^{(k)}(t)^{r_k} = th(t) - t \sum_j g_j(t) y^{(j)}(t)^{r_j}. \]

The \( k \)-index \((j - \text{index})\) set is composed of those \( k \) \((j)\) whose associated \( p_k \) \((p_j)\) satisfy the inequality \( p_k > r_k(n - k - 1) + 1 \) \((p_j > r_i(n - j - 1) + 1)\).

Notice that

\[ \lim_{t \to \infty} y^{(n-1)}(t)/\ln t = \lim_{t \to \infty} ty^{(n)}(t) = a_{n-1} \]

provided the latter limit exists. Rewriting (4.8) leads to the equation

\[ ty^{(n)} + \sum_k t^{p_k} g_k(t) \left( \frac{y^{(k)}(t)}{\ln t} \right)^{r_k} (\ln t)^{r_k} t^{(n-k-1)-p_k+1} \]

\[ = th(t) - \sum_j t^{p_j} g_j(t) \left( \frac{y^{(j)}(t)}{\ln t} \right)^{r_j} (\ln t)^{r_j} t^{(n-j-1)-p_j+1}. \]
Taking the limit as \( t \) approaches infinity gives \( \lim_{t \to \infty} ty^{(p)}(t) = \pm \infty \). This is a contradiction and completes the proof of the theorem.

**Remark 4.1.** If \( r \leq 1 \), the condition of Theorem 4.2 is necessary and sufficient for all solutions to have the asymptotic behavior \( y^{(q)}(t)/t^{\rho - 1} \ln t \sim a_1 \neq 0 \). This follows immediately from the first sentence in the statement of Theorem 4.1 and the result of Theorem 4.2.

A simple example in the linear case may be given to show that the signs of the \( c_i \) must all be the same. Asymptotic behavior of the type \( y^{(q)}(t)/t^{\rho - 1} \ln t \sim a_1 \neq 0 \), \( i = 0, 1, \ldots, n - 1 \), will now be considered. The \( r_i \) will be restricted such that \( 0 < r_i \leq 1 \), \( i = 0, 1, \ldots, n - 1 \). From Remark 4.1, the only \( p_i \) which need be considered are the ones which satisfy the inequality \( p_i \leq r_i(n - i - 1) + 1 \).

**Corollary 4.1.** Let (2.1.1), (2.1.2), (2.9), (2.10), and (4.1) be satisfied. If \( \rho \geq n - 1 \), then no solution \( y(t) \) of (2.8) has the asymptotic behavior

\[
y^{(q)}(t)/t^{\rho - 1} \ln t \sim a_1 \neq 0.
\]

**Proof.** Suppose \( p_i \leq r_i(\rho - j) + 1 \) for some \( j \) and some solution \( y(t) \) of (2.8) has the asymptotic behavior \( y^{(q)}(t)/t^{\rho - 1} \ln t \sim a_1 \neq 0 \). Write equation (2.8) as

\[
y^{(n)} + t \sum_k g_k(t) [y^{(k)}(t)]^{x_k} = th(t) - \sum_j g_j(t) [y^{(j)}(t)]^{x_j},
\]

where the \( k \)-index \((j\)-index\) set consists of those \( k \) \((j)\) whose associated \( p_k \) \((p_j)\) satisfy the inequality \( p_k > r_k(\rho - k) + 1 \) \((p_j \leq r_j(\rho - j) + 1)\). Taking the limit as \( t \) approaches infinity in (4.9) gives

\[
\lim_{t \to \infty} ty^{(n)}(t) = b_{-1} - \sum_j c_j a_j^{r_j} \lim_{t \to \infty} t^{r_j(\rho - j) - p_j + 1}(\ln t)^{r_j}.
\]

Since \( p_j \leq r_j(\rho - j) + 1 \), the limit on the right side of (4.10) is \( \pm \infty \). This is a contradiction and therefore \( p_i > r_i(\rho - i) + 1 \) for all \( i = 0, 1, \ldots, n - 1 \). But, since \( \rho \geq n - 1 \),

\[
p_i > r_i(\rho - i) + 1 \geq r_i(n - i - 1) + 1.
\]

This result contradicts Remark 4.1 and the corollary is proved.

5. Forcing terms with primary part \( t^\rho e^{bt} \). In this section forcing functions having primary part \( t^\rho e^{bt} \) will be considered. Specifically, the forcing term is to satisfy the following properties.

\[
h(t) = H(t)t^\rho e^{bt} + R(t),
\]

where \( h(t) \) is continuous for \( t \geq t_0 \);

\[
\lim_{t \to \infty} H(t) = A \neq 0;
\]

and

\[
R(t) = o(t^\rho e^{bt}) \text{ as } t \to \infty.
\]
If \( b < 0 \), \( h(t) \) is integrable and the forcing function is included in the class of forcing terms of §2. If \( b = 0 \), the primary part of the forcing function is a power of \( t \). §§2, 3, and 4 give results for forcing functions of this type. The purpose of this section is to consider forcing terms with primary part \( t^m e^{bt} \) where \( b > 0 \).

**Theorem 5.1.** Let conditions (2.1), (3.1), and (5.1) be satisfied; \( b > 0, \) \( 0 < r_i \leq 1 \) for all \( i = 0, 1, \ldots, n - 1 \); furthermore, if \( r_i = 1 \), it is required that \( n < p_i \). Under these hypotheses, all solutions \( y(t) \) of (1.1) have the asymptotic behavior \( y^{(i)}(t)/t^m e^{bt} \sim a_i \neq 0, \) \( i = 0, 1, \ldots, n - 1 \).

**Proof.** The argument proceeds as in the previous Theorems 2.1, 3.1, and 4.1; for this reason it will only be sketched here. The form of equation (1.1) which is used is

\[
y^{(k)}(t) \bigg/ t^m e^{bt} = \frac{\theta_0 + \theta_1 t + \cdots + \theta_{n-k-1} t^{n-k-1}}{t^m e^{bt}}
\]

(5.2)

\[
+ e^{-bt} t^{-m} \int_0^t \frac{(t-s)^{n-k-1}}{(n-k-1)!} h(s) \, ds
\]

\[
- e^{-bt} t^{-m} \int_0^t \frac{(t-s)^{n-k-1}}{(n-k-1)!} f(s, y(s), \ldots, y^{(n-1)}(s)) \, ds.
\]

The boundedness of each term will be investigated. It is clear that the first two terms on the right in (5.2) are bounded. Proceeding as before with \( T \) as previously chosen and with the additional requirement that the function

\[
X(t) = [t^{m-n+k+1} e^{bt}]^{-1}
\]

is decreasing for \( t \geq T \), we obtain

\[
\left| y^{(k)}(t) \bigg/ t^m e^{bt} \right| \leq C_k + B_k \int_T^t \sum_{i=0}^{n-1} s^{n-m-k-1-p_i + r_i t e^{b(t-1)bs}} \left| y^{(i)}(s) \bigg/ s^m e^{bs} \right|^{r_i} ds.
\]

If the sum \( \sum_{i=0}^{n-1} \left| y^{(i)}(t)/t^m e^{bt} \right| \leq 1 \) for all large \( t \), then clearly \( \sum_{i=0}^{n-1} \left| y^{(i)}(t)/t^m e^{bt} \right| \) is bounded. If \( \sum_{i=0}^{n-1} \left| y^{(i)}(t)/t^m e^{bt} \right| > 1 \), then \( \sum_{i=0}^{n-1} \left| y^{(i)}(t)/t^m e^{bt} \right| r_i \leq \sum_{i=0}^{n-1} \left| y^{(i)}(t)/t^m e^{bt} \right| \). Therefore,

\[
\sum_{k=0}^{n-1} \left| y^{(k)}(t) \bigg/ t^m e^{bt} \right| \leq \sum_{k=0}^{n-1} C_k + \sum_{k=0}^{n-1} B_k \int_T^t \sum_{i=0}^{n-1} s^{n-m-k-1-p_i + r_i t e^{b(t-1)bs}} \sum_{i=0}^{n-1} \left| y^{(i)}(s) \bigg/ s^m e^{bs} \right|^{r_i} ds.
\]

Applying Theorem 1.1, we obtain the inequality

\[
\sum_{k=0}^{n-1} \left| y^{(k)}(t) \bigg/ t^m e^{bt} \right| \leq C \exp \int_T^t \sum_{k=0}^{n-1} B_k \sum_{i=0}^{n-1} s^{n-m-k-1-p_i + r_i t e^{b(t-1)bs}} ds.
\]
By hypothesis, the above integrals converge and thus, \( \sum_{i=0}^{n-1} |y^{(k)}(t)/t^m e^{bt}| \) is bounded. Proceeding as in the previous proofs, the result
\[
\lim_{t \to \infty} y^{(i)}(t)/t^m e^{bt} = a_i = 0, \quad i = 0, 1, \ldots, n - 1,
\]
may be obtained.

**Remark 5.1.** This theorem or theorems determining existence of solutions having the above type of asymptotic behavior may not be demonstrated for nonlinearity involving higher powers. Consider the following example:
\[
y^{(n)} + ty' = e^t,
\]
where \( p \) is arbitrary and \( r > 1 \). Suppose some solution \( y(t) \) has the asymptotic behavior \( y(t)/e^t \sim a \neq 0 \). If \( \lim_{t \to \infty} y^{(n)}/e^t \) exists, necessarily, \( \lim_{t \to \infty} y^{(n)}/e^t = a \).
Thus, from the equation,
\[
\frac{y^{(n)}}{e^t} + t^p \frac{y'}{e^t} e^{(r-1)t} = 1;
\]
we obtain \( \lim_{t \to \infty} y^{(n)} e^{-t} = \pm \infty \). This is a contradiction and the desired asymptotic behavior is impossible.
