DISCRETE SUFFICIENT SETS FOR SOME SPACES OF ENTIRE FUNCTIONS

BY

B. A. TAYLOR

Abstract. Let $E$ denote the space of all entire functions $f$ of exponential type (i.e. $|f(z)| = O(\exp(B|z|))$ for some $B>0$). Let $\mathcal{K}$ denote the space of all positive continuous functions $k$ on the complex plane $\mathbb{C}$ with $\exp(B|z|) = O(k(z))$ for each $B>0$. For $k \in \mathcal{K}$ and $S \subseteq \mathbb{C}$, let $\|f\|_{k,S} = \sup \{|f(z)|/k(z) : z \in S\}$. We prove that the two families of seminorms $\{\|f\|_{k,C}\}_{k \in \mathcal{K}}$ and $\{\|f\|_{k,S}\}_{k \in \mathcal{K}}$, where

$$S = \{n+im : -\infty < n, m < +\infty\},$$

determine the same topology on $E$.

1. Introduction. Let $E = \{f \text{ entire} : |f(z)| \leq A \exp(B|z|) \text{ for some } A, B > 0\}$ denote the vector space of entire functions of exponential type, and let $\mathcal{K}$ denote the space of all positive continuous functions $k(z)$ on the complex plane $\mathbb{C}$ such that $\exp(A|z|) = O(k(z))$ as $|z| \to \infty$ for each $A > 0$. For each subset $S$ of $\mathbb{C}$, $f \in E$, and each $k \in \mathcal{K}$, define

$$\|f\|_{k,S} = \sup \{|f(z)|/k(z) : z \in S\}.$$

When $S = \mathbb{C}$, write $\|f\|_k$ for $\|f\|_{k,C}$. The seminorms $\|f\|_k$ determine a locally convex topology on $E$ which has been shown by L. Ehrenpreis [3, Chapter 5] (see also [10]) to be of interest in the study of several problems concerning entire functions. He has also posed the following question [3, p. 173]. Call a subset $S$ of $\mathbb{C}$ sufficient if the seminorms $\|f\|_{k,S}$ determine the same topology on $E$ as do the seminorms $\|f\|_k$. Are the lattice points $\{n + im : n, m = 0, \pm 1, \pm 2, \ldots\}$ a sufficient set? We prove here that this is the case.

The above problem is one of estimating entire functions which are “not too large” from their values at the lattice points, and such problems have been discussed by several authors (see e.g. [2], [5], [7], [8], [11], [12], [13], [14]). Work along these lines seems to have started from a problem posed by Littlewood and solved by G. Pólya, J. M. Whittaker, and others (see [12]). Namely, if $f$ is an entire function which is bounded at the lattice points and if

$$M(r,f) = \sup \{|f(z)| : |z| = r\}$$

207
satisfies \( \log M(r, f) = o(r^2) \), then \( f \) must be a constant. In connection with this problem, Whittaker has discussed the notion of "flat regions" of entire functions [14] (see also [7] and [8]). The work presented here was motivated by that of Whittaker and we have, in fact, given uniform versions of estimates similar to those proved by him (e.g. compare Lemma 3 with Lemma 504 of [14]). Other results related to the ones proved here are due to V. Ganapathy Iyer [5], whose notion of an "effective" set is about the same as a sufficient set.

One reason for determining "small" sufficient sets is that a set \( S \) is sufficient if and only if every entire function \( F(z) \) can be represented as an absolutely convergent Fourier integral

\[
F(z) = \int e^{izw} \, dv(w)
\]

where the measure \( v \) is supported on the set \( S \) [3, p. 12, or 4]. Thus, we obtain as a corollary the following fact.

**Corollary.** Every entire function \( F \) can be represented in the form

\[
F(z) = \sum_{n, m = -\infty}^{+\infty} a_{n, m} e^{i(n + im)z}
\]

where \( |a_{n, m}| (n^2 + m^2)^{-1/2} \to 0 \) as \( n^2 + m^2 \to +\infty \).

The expansion for \( F \) is never unique.

2. If \( S \) is a subset of \( \mathbb{C} \), denote by \( \rho(z, S) \) the distance from \( z \in \mathbb{C} \) to \( S \).

**Theorem 1.** If \( \rho(z, S) \leq 1 \) for all \( z \in \mathbb{C} \), then \( S \) is a sufficient set.

Theorem 1 will be deduced from the following estimate for entire functions and the lemma following it. For an entire function \( f \), let

\[
M(r, f) = \sup \{|f(z)| : |z| = r \}
\]

be the maximum modulus function of \( f \) and let

\[
M(r, f; S) = \sup \{|f(z)| : |z| \leq r, z \in S \}.
\]

**Theorem 2.** Let \( S \subset \mathbb{C} \) be such that \( \rho(z, S) \leq 1 \) for all \( z \in \mathbb{C} \), and let \( f \) be an entire function with \( f(0) = 1 \). There are absolute constants \( C_1, C_2, C_3 > 0 \) such that, for all \( r \geq 8 \),

\[
\log M(r, f) \leq \log^+ M(2r, f; S) + C_1 \left\{ \frac{\log M(C_2r)}{r} + \left( \frac{\log M(C_2r)}{r} \right)^2 \right\} + C_3 r.
\]

**Lemma 1.** Let \( u(r), \varphi(r) \) be positive, increasing, continuous functions defined for \( r \geq 8 \) and such that for some positive constants \( C_1, C_2, C_3, K \geq 1 \)

(i) \( \sup_r (\varphi(C_2r)/\varphi(r)) \leq K \),

(ii) \( r = o(\varphi(r)) \),

(iii) \( \varphi(r) = o(r^2) \).
(iv) \( u(r) = o(\varphi(r)) \),
(v) \( u(r) \leq \varphi(r) + C_3 r + C_1 (u(C_2 r)/r + (u(C_2 r)/r)^2) \).

Then there is a number \( r_0 > 0 \), depending only on \( \varphi \), \( C_1 \), \( C_2 \), \( C_3 \), \( K \) (and not on \( u(r) \)) such that, for all \( r \geq r_0 \), \( u(r) \leq 2(\varphi(r) + C_3 r) \).

We will first deduce Theorem 1 from Theorem 2 and Lemma 1.

**Proof of Theorem 1.** Clearly the topology on \( E \) induced by the seminorms \( \| \cdot \|_{k, s} \) is weaker than that induced by the seminorms \( \| \cdot \|_k \). Thus, we have to show that given any \( k \in \mathcal{K} \), there exists \( k_1 \in \mathcal{K} \) and \( C > 0 \) such that

\[
\| f \|_k \leq C \| f \|_{k_1, s}.
\]

Actually, we are going to prove an estimate of the form

\[
\| f \|_k \leq C(\| f \|_{k_1, s})^2 + D
\]

where \( C, D \) are constants, but (1) follows from this by applying (2) to the function \( \lambda f \) and then setting \( \lambda = \| f \|_k / 2C(\| f \|_{k_1, s})^2 \).

Let \( k \in \mathcal{K} \). It is no loss of generality to assume that \( 0 \in S \), that \( k(0) = 1 \), and that \( k(z) = \exp(\varphi(|z|) + 2C_3 |z|) \) where \( \varphi \) is an increasing function satisfying (i)–(iii) of Lemma 1 and \( C_3 \) is the constant appearing in Theorem 2. Then set

\[
k_1(z) = \exp(\varphi(|z|/2)).
\]

Now if \( f(0) = 1 \) and \( \| f \|_{k_1, s} \leq A \) we have by Theorem 2 that

\[
\log M(r, f) \leq \frac{1}{2} \varphi(r) + C_3 r + \log A + C_1 \left\{ \frac{\log M(C_2 r, f)}{r} + \left( \frac{\log M(C_2 r, f)}{r} \right)^2 \right\}.
\]

Since \( k_1(0) = k(0) = 1 \) we have

\[
1 \leq \| f(0)/k_1(0) \| \leq \| f \|_{k_1, s} \leq A
\]

so we may apply Lemma 1 to deduce that there exists \( r_0 > 0 \), independent of \( f \) and \( A \geq 1 \), such that \( \log M(r, f) \leq \varphi(r) + 2C_3 r + 2 \log A \) or \( |f(re^{it})| \leq A^2 k(re^{it}) \) for \( r \geq r_0 \). If \( r \leq r_0 \) and if \( C = \max \{ k(r)/k(r) : 0 \leq r \leq r_0 \} \), then we have \( \| f \|_k \leq CA^2 \). That is, if \( f(0) = 1 \), then

\[
\| f \|_k \leq C(\| f \|_{k_1, s})^2.
\]

If \( |f(0)| \geq 1 \), then we may apply (3) to \( f/f(0) \) to deduce that the same inequality holds. If \( |f(0)| \leq 1 \), then

\[
\| f \|_k = \| f - (f(0) - 1) + (f(0) - 1) \|_k
\]

\[
\leq \| f - (f(0) - 1) \|_k + \| f(0) - 1 \|_k
\]

\[
\leq C(\| f - (f(0) - 1) \|_{k_1, s})^2 + \sup \{ 2/k(z) : z \in C \}.
\]

Now \( \| f - (f(0) - 1) \|_{k_1, s} \leq \| f \|_{k_1, s} + \| f(0) - 1 \|_{k_1, s} \) and \( (a+b)^2 \leq 2(a^2 + b^2) \) so when, \( |f(0)| \leq 1 \), \( \| f \|_k \leq 2C(\| f \|_{k_1, s})^2 + D \) where \( D = \sup \{ 2/k(z) \} + \sup \{ 8C/(k_1(z))^2 \} \) and
the supremums are over \( z \in \mathbb{C} \). Taken together with (3), this proves (2), which, completes the proof of Theorem 1.

It remains to prove Lemma 1 and Theorem 2. We first prove the lemma.

**Proof of Lemma 1.** Let \( \psi(r) = 2(\varphi(r) + C_3r) \). Since \( r = o(\varphi(r)) \) and \( \varphi(r) = o(r^2) \), there exists \( r_0 > 0 \) such that, for all \( r \geq r_0 \), \( \varphi(r) \geq r \) and

(4) \[ r^2 \geq 8C_1(\varphi(C_2r) + C_3C_2r) \cdot \max(K, C_2) \]

where

\[ K = \sup \{ \varphi(C_2r)/\varphi(r) : r \geq 0 \} \]

Suppose by way of contradiction that \( u(r) \leq \varphi(r) \) for some \( r \geq r_0 \). Then from (v) we have, since \( u(C_2r)/r \geq u(r)/r \geq 1 \),

(5) \[ \varphi(r) + C_3r \leq 2C_1[u(C_2r)/r]^2. \]

However, by (i),

\[ \varphi(r) + C_3r = [\varphi(C_2r)\varphi(r)/\varphi(C_2r)] + [C_3C_2r/C_2] \]

\[ \geq \left[ \max(K, C_2) \right]^{-1}(\varphi(C_2r) + C_3C_2r), \]

so (5) together with (4) implies that \( u(C_2r) \geq \varphi(C_2r) \). Repeating the above argument, we find that, for every \( n = 1, 2, \ldots, u(C_2r) \geq \varphi(C_2r) \) which, together with (ii) and (iv), is a contradiction. Thus, \( u(r) \leq \varphi(r) \) for all \( r \geq r_0 \), as asserted.

To give the proof of Theorem 2 we introduce the following notation and prove three (easy) lemmas. Let the zeros of the entire function \( f \) be denoted by \( \{z_j\} \). Here we use the standard convention that each zero is repeated in the sequence \( \{z_j\} \) as many times as its multiplicity as a zero of \( f \). For each \( \zeta \in \mathbb{C} \) and \( t > 0 \), let

\[ n(t, \zeta) = \sum_{|z_j - \zeta| \leq t} 1 \]

denote the number of \( z_j \) in the disc \( |z - \zeta| \leq t \). Write \( n(t) \) for \( n(t, 0) \) and let \( \lambda \) denote Lebesgue measure on \( \mathbb{C} \).

**Lemma 2.** Let \( R \geq 4 \). Then \( n(2, \zeta) = 0 \) except possibly for a set of \( \zeta \) in \( |\zeta| \leq R/2 \) of Lebesgue measure at most \( 4\pi n(R) \).

**Proof.** Obvious.

The next lemma is essentially Lemma 504 of [14].

**Lemma 3.** Let \( R > 0 \). Then for all \( |\zeta| \leq R/2 \) and every \( \delta > 0 \)

\[ n(t, \zeta) \leq \frac{4C}{\pi \delta} \frac{n(R, 0)}{R^2} t^2, \quad 1 \leq |t| \leq R/2, \]

except possibly for \( \zeta \) in a set of Lebesgue measure not exceeding \( \pi \delta R^2 \). Here \( C \) is an absolute constant.
Proof. For every \( z_\epsilon \) with \( |z_\epsilon| \leq R \), let \( h_\epsilon(z) = 1 \) if \( |z - z_\epsilon| \leq 1 \) and \( h_\epsilon(z) = 0 \) otherwise. Then let \( h = \sum h_\epsilon \), \( |z_\epsilon| \leq R \). Obviously, \( \|h\|_1 = \int h \, d\lambda = \pi n(R) \). Furthermore, if we set

\[
v(t, z) = \int_{|z - z_\epsilon| \leq t} h(z) \, d\lambda(z)
\]

then, for all \( t \geq 0 \), \( v(t, z) \leq \pi n(t + 1, z) \) and, for \( |t| \leq R - |z| \), \( \pi n(t, z) \leq v(t + 1, z) \).

Define \( h^*(z) = \sup \{v(t, z)(\pi t^2)^{-1} : t > 0\} \) to be the maximal function associated with \( h \). By a theorem of Hardy and Littlewood (see e.g. [9]), there is a constant \( C > 0 \) such that

\[
\lambda\{z : h^*(z) > \epsilon\} \leq (C/\epsilon)\|h\|_1 = (C\pi/\epsilon)n(R, 0).
\]

Choose \( \epsilon \) so that \( (C/\epsilon)n(R, 0) = \delta R^2 \). Then

\[
n(t, z) \leq (\pi)^{-1}v(t + 1, z) \leq \frac{C}{\delta} \frac{n(R, 0)}{R^2} (t + 1)^2
\]

except for \( z \) in a set of measure not exceeding \( \pi \delta R^2 \). When \( |z| \leq R/2 \) and \( 1 \leq t \leq R/2 \), (6) implies the inequality of the lemma.

For \( x > 0 \), let \( \log^+ x = \max(\log x, 0) \), and \( \log^- x = \log^+ x - \log x = -\min(\log x, 0) \).

Lemma 4. Suppose \( R \geq 12 \) and that \( f \) is analytic for \( |z| \leq R \), with zeros \( \{a_n\} (a_n \neq 0) \). Then for all complex numbers \( z \) with \( |z| \leq 1 \), we have either

\[
\log |f(z)| \leq \frac{12}{R\pi} \int_{-\pi}^{\pi} \log^+ |f(Re^{it})| \, d\theta
\]

or else

\[
|\log |f(0)| - \log |f(z)|| \leq \frac{12}{R\pi} \int_{-\pi}^{\pi} \log^+ |f(Re^{it})| \, d\theta + 2K \sum_{2 \leq |a_n| \leq R} |a_n|^{-1} + \left| \sum_{|a_n| < 2} \log \left| \frac{R^2(z - a_n)}{an(R^2 - a_n^2)} \right| \right|
\]

Proof. We have by the Poisson-Jensen formula [6, p. 1] that \( \log |f(z)| = u(z) + v(z) \) where

\[
u(z) = \sum \log \left| \frac{R(z - a_n)}{R^2 - \bar{a}_n z} \right| \leq 0
\]

and

\[
v(z) = \frac{1}{2\pi} \int_{-\pi}^{\pi} P(R, \theta, z) \log |f(Re^{it})| \, d\theta,
\]

where \( P(R, \theta, z) = (R^2 - |z|^2)/|Re^{it} - z|^2 \). With \( \log^+ |f| = \max(\log |f|, 0) \) and \( \log^- |f| = -\min(\log |f|, 0) \), we have from (7) that

\[
\frac{1}{2\pi} \int_{-\pi}^{\pi} \log^+ |f(Re^{it})| \, d\theta = \frac{1}{2\pi} \int_{-\pi}^{\pi} \log^+ |f(Re^{it})| \, d\theta - v(0).
\]
Now, for \(|z| \leq 1\) and \(R \geq 2\) we have
\[
|P(R, \theta, z) - P(R, \theta, 0)| \leq 2|z|(R + |z|)/(R - |z|)^2 \leq 12/R,
\]
so that
\[
|v(0) - v(z)| \leq \frac{6}{R\pi} \int_{-\pi}^{\pi} |\log |f(Re^{i\theta})|| \, d\theta
\]
\[
\leq \frac{12}{R} \left( \frac{1}{\pi} \int_{-\pi}^{\pi} \log^+ |f(Re^{i\theta})| \, d\theta - v(0) \right).
\]
If \(v(0) \leq 0\), then for \(R \geq 12\) it follows that \(v(z) \leq (12/R\pi) \int_{-\pi}^{\pi} \log^+ |f(Re^{i\theta})| \, d\theta\) which implies the first estimate of the lemma because \(\log |f(z)| \leq v(z)\). Thus, we may assume \(v(0) \geq 0\) so that
\[
|v(0) - v(z)| \leq \frac{12}{R\pi} \int_{-\pi}^{\pi} \log^+ |f(Re^{i\theta})| \, d\theta.
\]
Next, we have
\[
\log \left| \frac{a}{R} \right| - \log \left| \frac{R(z - a)}{R^2 - \bar{a}z} \right| = -\log \left| 1 - \frac{z}{a} \right| + \log \left| 1 - \frac{\bar{a}z}{R^2} \right|
\]
so if \(K\) is any constant such that \(\log (1 - |\xi|) \leq K|\xi|\) for \(|\xi| \leq \frac{1}{2}\), then for \(|z| \leq 1\),
\[
|u(0) - u(z)| \leq \sum_{|a_n| < 2} \log \left| \frac{R^2(z - a_n)}{a_n(R^2 - \bar{a}_nz)} \right| + K \sum_{2 \leq |a_n| \leq R} \left( \frac{1}{|a_n|} + \frac{1}{R} \right).
\]
Since \(|a_n| \leq R\), the last estimate of the lemma follows from (8) and (9).

**Proof of Theorem 2.** Let \(a \in \mathbb{C} \), with \(3|a|/2 \geq 12\). Since \(\log |f|\) is subharmonic, \(\log |f(a)|\) does not exceed the average of \(\log |f|\) over the disc
\[
D_a = \{z : |z - a| \leq |a|/2\}.
\]
Consequently, if \(E\) is any subset of this disc, we have
\[
\log |f(a)| \leq \frac{4}{\pi|a|^2} \left\{ \int_{E} + \int_{D_a\setminus E} \log |f| \, dl \right\}
\]
\[
\leq \sup_{z \in E} \{\log |f(z)|\} + \frac{4\lambda(D_a\setminus E)}{\pi|a|^2} \log M(\frac{3}{2}|a|, f)
\]
where \(D_a\setminus E\) is the complement of \(E\) in \(D_a\).

Now, choose \(\delta = n(3|a|, 0)/|a|^2\) and let \(E\) denote the set of points in \(D_a\) such that \(n(2, \xi) = 0\) and
\[
n(t, \xi) \leq \frac{4C}{9\pi\delta} \frac{n(3|a|, 0)}{|a|^2} t^2, \quad 1 \leq t \leq \frac{3|a|}{2},
\]
where \(C\) is as in Lemma 3. If we apply Lemmas 2 and 3 with \(R = 3|a|\), we see that
\[
\lambda(D_a\setminus E) \leq 4\pi n(3|a|, 0) + 9\pi\delta |a|^2 = 13\pi n(3|a|, 0).
\]
If \(\xi \in E\), then apply Lemma 4 to the function \(z \rightarrow f(\xi + z)\), with \(R = 3|a|/2\) to obtain
SUFFICIENT SETS FOR SPACES OF ENTIRE FUNCTIONS

\[
\log |f(\zeta)| \leq \sup \{\log^+ |f(z)| : z \in S, |z| \leq 3|a|/2 + 1\}
+ \frac{16}{|a|} \log M(3|a|, f) + 2K \sum_{z_n \in A \setminus \mathbb{R}} \frac{1}{|z_n - \zeta|^2}.
\]

However,

\[
\sum_{z_n \in A \setminus \mathbb{R}} \frac{1}{|z_n - \zeta|} = \int_2^R t^{-1} \frac{dn(t, \zeta)}{t^2} \leq \frac{n(R, \zeta)}{R} + \int_2^R \frac{n(t, \zeta)}{t^2} dt.
\]

By (11) the last integral does not exceed

\[
\frac{4C}{\pi^3} \frac{n(3|a|, 0)}{9|a|^3} \cdot \frac{3|a|}{2} = \frac{2C}{\pi^3} |a|
\]

so that

\[
\log |f(\zeta)| \leq \log^+ M(2|a|, f, S) + \left(\frac{16}{|a|}\right) \log M(3|a|, f)
+ K \frac{n(3|a|, 0)}{3|a|} + \frac{4CK}{\pi^3} |a|.
\]

Since for all \(r > 0\), \(n(r, 0) \leq \log M(r, f) - \log |f(0)|\), the theorem follows directly from (10), (12) and (13).

Remark 1. Exactly the same argument shows that any set \(S\) with \(\rho(z, S) \leq 1\) is sufficient for the analytically uniform spaces of [10] for which the weights \(k\) can be taken in the form \(k(z) = \exp(\varphi(|z|))\) where \(\varphi(z) = o(|z|^2)\) and for which \(k_1(z) = k_1^2(2z)\) belongs to \(\mathcal{K}\) whenever \(k \in \mathcal{K}\).

Remark 2. The condition \(\rho(z, S) \leq 1\) in Theorems 1 and 2 may obviously be replaced by \(\rho(z, S) \leq d\) for \(d\) any positive constant.
