HENSELIAN VALUED FIELDS
WITH PRESCRIBED VALUE GROUP AND RESIDUE FIELD

BY

LINDA HILL

ABSTRACT. A class of fields supplementary to the inertia field of a
given henselian valued field is used to construct extensions of that field
having prescribed value group and residue field. The extensions so-con-
structed are characterized, and their number investigated.

1. Introduction. The construction of valued fields extending a given one and
having prescribed value groups and residue fields with respect to the extensions
of the given valuation has received much attention in the literature from many
points of view; see [1], [2], [3], [5], [6], [7], [8], [11], [12], for example. The
general problem, that of finding an extension L of a given Krull-valued field
(K, A) such that the extensions of A to L realize prescribed value groups and
residue fields, or, more generally, realizing simultaneously such prescriptions
for the extensions of an entire tree of valuation rings of K, has yielded to a
method initiated by Endler in [3] and Chapter IV of [4], for rank 1 Krull valua-
tions and extended by the present author in [6] to a class of Krull valuations of
finite rank. That is the realization of each prescribed value group and residue
field extension by an extension of the henselization (completion, in the rank 1
case) of the given valued field, coupled with the realization of those fields as
the henselizations of some single extension L of K. Since a henselization of
any valued field is an immediate extension of that field, the realization of pre-
scribed value group and residue field extensions is achieved. Thus, the exis-
tence of extensions of a given henselian valued field having prescribed value
group and residue field is of much interest. This paper presents a method for the
construction of such fields and offers characterizations of the fields so-con-
structed. Offered also is a discussion of the number of extensions realizing a
given prescription; some open questions on the subject are listed.

2. Preliminaries and notation. Throughout this work, if A and B are any pair
of groups, rings, or fields, with A ⊆ B, we will denote by \{B | A\} the lattice
Let \((K, A)\) be a (Krull-)valued field, \(\Omega\) a separable closure of \(K\), and \(C\) an extension of \(A\) to \(\Omega\). We will denote by \(\zeta_C\) the place of \(\Omega\) determined by \(C\) and will write, for any \(L \in \{\Omega \mid K\}, \zeta_CL\) for the residue field \(\zeta_{\cap L}(L)\); we write \(\Gamma_C L\) for the value group \(v_{C \cap L}(L)\). Within the extension \(\Omega \mid K\) one finds the well-known intermediate fields \(K^Z(C), K^T(C),\) and \(K^V(C)\), the decomposition field, inertia field, and ramification field, respectively, of \(C\) over \(K\).

The fundamental properties of these fields which will be used in the present work are:

(2.1) \((K^Z(C), C \cap K^Z(C))\) is a henselian valued field, minimal in \(\{\Omega \mid K\}\) with respect to that property, and is an immediate extension of \((K, A)\). The field \((K, A)\) is henselian exactly in case \(K^Z(C) = K\).

(2.2) \((K^T(C), C \cap K^T(C))\) is an unramified extension of \((K, A)\) and is the unique maximal member of \(\{\Omega \mid K^Z(C)\}\) with respect to that property; it is normal over \(K^Z(C)\). Thus \(\Gamma_C(K^T(C)) = \Gamma_C K; \zeta_C(K^T(C)) = \zeta_C \Omega\), an algebraic closure of \(\zeta_A K\). The place \(\zeta_C\) is an order-preserving, degree-preserving lattice-isomorphism from \(K^T(C) \mid K^Z(C)\) onto \(\{\zeta_C \Omega \mid \zeta_A K\}\). The Galois groups \(\text{Aut}(K^T(C) \mid K^Z(C))\) and \(\text{Aut}(\zeta_C \Omega \mid \zeta_A K)\) are isomorphic. For any member \(L\) of \(\{K^V(C) \mid K^Z(C)\}\), \(L \cap K^T(C)\) is the unique member of \(\{K^T(C) \mid K^Z(C)\}\) having residue field \(\zeta_CL\).

(2.3) \((K^V(C), C \cap K^V(C))\) is a tamely ramified extension of \((K, A)\) and contains every finite defectless (see [4]) tamely ramified extension \((L, C \cap L)\) of \((K, A)\) within \((\Omega, C)\); it is normal over both \(K^T(C)\) and \(K^Z(C)\). The valuation \(v_C\) is an order-preserving, degree-preserving lattice-isomorphism from \(K^V(C) \mid K^T(C)\) to \(\{\Gamma(K^V(C)) \mid \Gamma K\}\). For any \(L \in \{K^V(C) \mid K^T(C)\}, L \cap K^T(C)\) is the unique member of \(\{K^V(C) \mid K^T(C)\}\) having value group \(\Gamma_CL\).

If the extension \(C\) of \(A\) to \(\Omega\) is considered fixed, we will denote \(K^Z(C), K^T(C),\) and \(K^V(C)\) by \(K^Z, K^T,\) and \(K^V\), respectively, and will omit reference to \(C\) in \(\Gamma_C, v_C,\) and \(\zeta_C\).

3. Neukirch complements. In his paper [10], Jürgen Neukirch established the existence of fields which we have chosen to call Neukirch complements, supplementary to the three fields discussed in §2 above. Namely, Neukirch showed that the exact sequence

\[
(3.1) \{1\} \to \text{Aut}(K^V \mid K^T) \to \text{Aut}(K^V \mid K^Z) \xrightarrow{j} \text{Aut}(K^V \mid K^T) / \text{Aut}(K^V \mid K^Z) \to \{1\}
\]
splits. A splitting of sequence (3.1) is obtained if a field \(K^S \in \{K^V \mid K^Z\}\) is found for which \(K^S \cdot K^T = K^V\) and \(K^S \cap K^T = K^Z\); Neukirch showed that the fields \(K^S\) with those properties are precisely the members of \(\{K^V \mid K^T\}\) maximal.
with respect to the property $K^S \cap K^T = K^Z$ (that is, that $\zeta K^S = \zeta K$); a simple Zorn’s lemma argument thus establishes the existence of such fields. We have called (see [6]) such a field $K^S$ a Neukirch complement for $K^T$ in $K^V$.

The main property of Neukirch complements which Neukirch establishes is:

**Theorem (3.2) (Neukirch).** The lattices $\{K^S \mid K^Z\}$ and $\{\Gamma K^S \mid \Gamma K^Z\} = \{\Gamma K^V \mid \Gamma K\}$ are in order-preserving, degree-preserving correspondence under the lattice-iso-

From $\Gamma K^V \mid \Gamma K$ onto $\{K^V \mid K^T\}$ preserves value groups. That composition is $L \mapsto L \cdot K^T$ with inverse $M \mapsto M$.

4. Neukirch-determinable extensions. Here and in the sequel we assume $(K, A)$ is henselian, so $K^Z = K$. If $L$ is any member of $\{K^V \mid K\}$, denote by $L^T$ the inertia field $L^T(C) = L \cdot K^T(C)$ of $C$ over $L$. The ramification field of $C$ over $L$ is $K^V$. The group $\text{Aut}(K^V \mid L)$ is a subgroup of $\text{Aut}(K^V \mid K)$, $\text{Aut}(K^V \mid L^T)$ is a subgroup of $\text{Aut}(K^V \mid K^T)$, and $\text{Aut}(K^V \mid L^T) \cap \text{Aut}(K^V \mid L) = \text{Aut}(K^V \mid L^T)$, so the following diagram commutes:

(4.1) $\{1\} \rightarrow \text{Aut}(K^V \mid K^T) \rightarrow \text{Aut}(K^V \mid K) \rightarrow \text{Aut}(K^V \mid K)/\text{Aut}(K^V \mid K^T) \rightarrow \{1\}$

(4.2) $\{1\} \rightarrow \text{Aut}(K^V \mid L^T) \rightarrow \text{Aut}(K^V \mid L) \rightarrow \text{Aut}(K^V \mid L)/\text{Aut}(K^V \mid L^T) \rightarrow \{1\}$

If $\eta: \text{Aut}(K^V \mid K)/\text{Aut}(K^V \mid K^T) \rightarrow \text{Aut}(K^V \mid K)$ is a splitting of sequence (4.1), then the restriction of $\eta$ to $\text{Aut}(K^V \mid L)/\text{Aut}(K^V \mid L^T)$ splits sequence (4.2) in such a way that the resulting diagram commutes, and only if $\eta(\text{Aut}(K^V \mid L)/\text{Aut}(K^V \mid L^T)) \subseteq \text{Aut}(K^V \mid L)$. In case this happens, we have called $L$ a Neukirch-determinable extension of $K$. If $\text{Im}(\eta) = K^S$, we also say that $L$ is a $K^S$-determinable extension of $K$. Clearly, then, $L$ is $K^S$-determinable if and only if $L \cdot K^S$ is a Neukirch complement for $L^T$ in $K^V$.

**Proposition (4.3).** If $L \in \{K^V \mid K\}$ and $K^S$ is a Neukirch complement for $K^T$ in $K^V$, then $L$ is $K^S$-determinable if and only if $L \cdot K^S \cap L \cdot K^T = L$. Further, for any member $L$ of $\{K^V \mid K\}$, the field $L \cdot K^S \cap L \cdot K^T$ is $K^S$-determinable.

**Proof.** By definition of Neukirch determinability, $L$ is $K^S$-determinable if and only if $\text{Aut}(K^V \mid K^S) \cap \text{Aut}(K^V \mid L)$ splits sequence (4.2), which happens if and only if

(i) $\text{Aut}(K^V \mid K^S) \cap \text{Aut}(K^V \mid L) \cap \text{Aut}(K^V \mid L \cdot K^T) = \{1\}$, and

(ii) $\text{Aut}(K^V \mid K^S) \cap \text{Aut}(K^V \mid L) \cdot \text{Aut}(K^V \mid L \cdot K^T) = \text{Aut}(K^V \mid L)$.

Condition (i) holds automatically, since $\text{Aut}(K^V \mid K^S) \cap \text{Aut}(K^V \mid K^T) = \{1\}$; condition (ii) is equivalent to the assertion $L \cdot K^S \cap L \cdot K^T = L$.

To check that $L \cdot K^S \cap L \cdot K^T$ is $K^S$-determinable, we use the criterion
just proved: Clearly we need only check that \((L \cdot K^S \cap L \cdot K^T) \cdot K^S \cap (L \cdot K^S \cap L \cdot K^T) \cdot K^T \subseteq L \cdot K^S \cap L \cdot K^T\). We have

\[
(L \cdot K^S \cap L \cdot K^T) \cdot K^S \cap (L \cdot K^S \cap L \cdot K^T) \cdot K^T
\]
\[
\subseteq L \cdot K^S \cap L \cdot K^T \cdot K^S \cap L \cdot K^T \cap L \cdot K^T
\]
\[
= L \cdot K^S \cap L \cdot K^T, \text{ as required.}
\]

**Remark (4.4).** Proposition (4.3) shows that a \(K^S\)-determinable extension of \(K\) is obtainable as the intersection of its inertia field and a Neukirch complement for that inertia field.

**Corollary (4.5).** Every member of \(\{K^V|K^S\}\) is \(K^S\)-determinable; every member of \(\{K^V|K^T\}\) is \(K^S\)-determinable for all Neukirch complements \(K^S\).

**Proof.** \(L \supseteq K^S\) entails \(L \cdot K^S \cap L \cdot K^T = L \cap L \cdot K^T = L\); similarly if \(L \supseteq K^T\).

**Corollary (4.6).** For each \(K^S\), the set of \(K^S\)-determinable extensions of \(K\) in \(K^V\) is closed under intersection.

**Proof.** If \(L\) and \(M\) are \(K^S\)-determinable, consider \((L \cap M) \cdot K^S \cap (L \cap M) \cdot K^T \subseteq (L \cdot K^S) \cap (M \cdot K^S) \cap (L \cdot K^T) \cap (M \cdot K^T) = (L \cdot K^S \cap L \cdot K^T) \cap (M \cdot K^S \cap M \cdot K^T)\). The other inclusion is trivial.

**Theorem (4.7).** A field \(L \in \{K^V|K\}\) is \(K^S\) determinable if and only if \(\Gamma(L \cap K^S) = \Gamma L\).

**Proof.** If \(L\) is \(K^S\)-determinable, then \(\operatorname{Aut}(K^V|L)\) is the semidirect product \(\operatorname{Aut}(K^V|L \cdot K^T) \times_\psi \operatorname{Aut}(K^V|L \cdot K^S)\); here the action \(\psi\) of \(\operatorname{Aut}(K^V|L \cdot K^S)\) on \(\operatorname{Aut}(K^V|L \cdot K^T)\) is induced by inner automorphisms of \(\operatorname{Aut}(K^V|L)\) on its abelian normal subgroup \(\operatorname{Aut}(K^V|L \cdot K^T)\). The statement \(\Gamma(L \cap K^S) = \Gamma L\) is equivalent to \((L \cap K^S) \cdot K^T = L \cdot K^T\), in turn equivalent to

\[
\operatorname{Aut}(K^V|L) \cdot [[1]] \times_\psi \operatorname{Aut}(K^V|K^S) \cap \operatorname{Aut}(K^V|K^T) \times_\psi [1] = \operatorname{Aut}(K^V|L \cdot K^T).
\]

Expressing \(\operatorname{Aut}(K^V|L)\) as the semidirect product which it is in case \(L\) is \(K^S\)-determinable, we have

\[
([\operatorname{Aut}(K^V|L \cdot K^T) \times_\psi \operatorname{Aut}(K^V|L \cdot K^S)] \cdot [[1]] \times_\psi \operatorname{Aut}(K^V|K^S)) \cap \operatorname{Aut}(K^V|K^T) = \operatorname{Aut}(K^V|L \cdot K^T).
\]

Conversely, let \(\operatorname{Aut}(K^V|L)\) be thought of as a subgroup of the semidirect product \(\operatorname{Aut}(K^V|K) = \operatorname{Aut}(K^V|K^T) \times_\eta \operatorname{Aut}(K^V|K^S)\). The map \(\eta: r \mapsto (1, r)\) splits.
sequence (4.2) provided \((\sigma, \tau) \in \text{Aut}(K^V\mid L)\) for some \(r \in \text{Aut}(K^V\mid K^S)\) = \(\text{Aut}(K^V\mid L \cdot K^T)\), yet the former set is exactly \(\text{Aut}(K^V\mid L) \cdot \text{Aut}(K^V\mid K^S) \cap \text{Aut}(K^V\mid K^T)\).

Remark (4.8). For all members \(L\) of \(\{K^V\mid K\}\), Neukirch-determinable or not, \(\zeta(L \cap K^T) = \zeta L\) (see [6]). Theorem (4.7) shows that the Neukirch-determinable extensions of \(K\) in \(K^V\) are exactly those for which the analogous statement holds for value groups.

Corollary (4.9). Every member of \(\{K^S\mid K\}\) is \(K^S\)-determinable.
Proof. If \(L \subseteq K^S\), then \(L \cap K^S = L\).

Corollary (4.10). All members of \(\{K^V\mid K^T\}\) and all members of \(\{K^T\mid K\}\) are \(K^S\)-determinable.
Proof. By Satz 5 of Neukirch’s work [10], the mapping \(L \mapsto L \cap K^S\) of \(\{K^V\mid K^T\}\) onto \(\{K^S\mid K\}\) preserves value groups. If \(L \subseteq K^T\) then \(\Gamma L = \Gamma K\) yet since \(K^T \cap K^S = K\), we know \(L \cap K^S = K\).

Corollary (4.11). \(L\) is \(K^S\)-determinable if and only if \((L \cap K^S) \cdot (L \cap K^T) = L\).
Proof. Clearly \((L \cap K^S) \cdot (L \cap K^T) \subseteq L\). Further, \(\Gamma((L \cap K^S) \cdot (L \cap K^T)) \cap K^S \supseteq L \cap K^S\), so
\[
\Gamma((L \cap K^S) \cdot (L \cap K^T)) \supseteq \Gamma(L \cap K^K),
\]
and \(\Gamma((L \cap K^S) \cdot (L \cap K^T)) \subseteq L \cap K^T\), so
\[
\zeta((L \cap K^S) \cdot (L \cap K^T)) = \zeta((L \cap K^S) \cdot (L \cap K^T)) \supseteq \zeta(L \cap K^T) = \zeta L.
\]
Thus \(\Gamma((L \cap K^S) \cdot (L \cap K^T)) \subseteq \Gamma((L \cap K^S) \cdot (L \cap K^T)) \subseteq \Gamma L\) and \(\zeta((L \cap K^S) \cdot (L \cap K^T)) = \zeta L\). If \(L\) is \(K^S\)-determinable, then \(\Gamma((L \cap K^S) \cdot (L \cap K^T)) = \Gamma L\), and by (22.2) of [4], we have
\[
[L : (L \cap K^S) \cdot (L \cap K^T)] = (\Gamma L : \Gamma((L \cap K^S) \cdot (L \cap K^T))) = (\zeta L : \zeta((L \cap K^S) \cdot (L \cap K^T))) = 1.
\]
Conversely, if \(L = (L \cap K^S) \cdot (L \cap K^T)\), we have \(\Gamma L = \Gamma(L \cdot K^T) = \Gamma((L \cap K^S) \cdot (L \cap K^T) \cdot K^T) = \Gamma((L \cap K^S) \cdot K^T) = \Gamma(L \cap K^S)\), so \(L\) is \(K^S\)-determinable.

Remark (4.12). Corollary (4.11) shows that a Neukirch-determinable extension is determined by its value group and residue field (hence the name). Indeed, \(L \cap K^S\) is the unique member of \(\{K^S\mid K\}\) having value group \(\Gamma L\) and \(L \cap K^T\) is the unique member of \(\{K^T\mid K\}\) having residue field \(\zeta L\). In terms of the lattice-isomorphisms \(\nu\) and \(\zeta\) of Theorem (3.2) and paragraph (2.2), respectively, \(L = \)
$v^{-1}(\Gamma L) \cdot \zeta^{-1}(\zeta L)$. If $L$ is $K^S$-determinable, then it is the only $K^S$-determinable extension of $K$ in $K^V$ having its value group and residue field.

Remark (4.13). For any $L \in |K^V |K|$, the field $(L \cap K^S) \cdot (L \cap K^T)$ is $K^S$-determinable and has value group $\Gamma(L \cap K^S)$ and residue field $\zeta L$; the verification is routine.

Remark (4.14). For any $K^S$ and for any prescription $(\Delta, \underline{\zeta})$ of value group and residue field with $\Delta \in |\Gamma K^V |K|$ and $\underline{\zeta} \in \{\zeta K^V |K|\} = \{\zeta K |K|\}$, there is a $K^S$-determinable extension of $K$ in $K^V$ having value group $\Delta$ and residue field $\underline{\zeta}$ (hence one and only one such field). For, let $L_1$ be the unique member of $|K^S|K|$ having value group $\Delta$, let $L_2$ be the unique member of $|K^T|K|$ having residue field $\underline{\zeta}$, and set $L = L_1 \cdot L_2$. We know, by Corollaries (4.9) and (4.10) and Corollary (4.15) below, that $L$ is $K^S$-determinable. We have $L \cdot K^T = L_1 \cdot L_2 \cdot K^T = L_1 \cdot K^T$ so $\Gamma L = \Gamma L_1 = \Delta$. $K^S$-determinability implies by Proposition (4.3) that $L = L \cdot K^S \cap L \cdot K^T = L_1 \cdot L_2 \cdot K^S \cap L_1 \cdot L_2 \cdot K^T = L_2 \cdot K^S \cap L_1 \cdot K^T$, so

$$L \cap K^T = L_2 \cdot K^S \cap L_1 \cdot K^T \cap K^T = L_2 \cdot K^S \cap K^T = L_2 K^S \cap L_2 K^T = L_2$$

since $L_2$ is $K^S$-determinable. Thus $\zeta L = \zeta (L \cap K^T) = \zeta L_2 = \underline{\zeta}$.

Corollary (4.15). The set of $K^S$-determinable extensions of $K$ in $K^V$ forms a sublattice of $|K^V |K|$.  

Proof. We need only show that the set of $K^S$-determinable extensions is closed under products. Suppose, then, that $L$ and $M$ are $K^S$-determinable, and consider $L \cdot M$. We have $(L \cdot M \cap K^S) \cdot (L \cdot M \cap K^T) \subseteq L \cdot M$, and $(L \cdot M \cap K^S) \cdot (L \cdot M \cap K^T) \supseteq (L \cap K^S) \cdot (M \cap K^S) \cdot (L \cap K^T) \cdot (M \cap K^T) = L \cdot M$ by Corollary (4.11).

Remark (4.16). Proposition (4.3), Corollary (4.5), and Corollary (4.15) show that the lattice of $K^S$-determinable extensions of $K$ in $K^V$ is precisely the sublattice of $|K^V |K|$ generated by $|K^V |K^S|$ and $|K^V |K^T|$. Corollaries (4.9), (4.10), and (4.11) show that that lattice is identical to the one generated by $|K^S|K|$ and $|K^T|K|$.

Corollary (4.17). Neukirch's lattice-isomorphisms between $|K^V |K^S|$ and $|K^T|K^Z|$ given by $L \mapsto L \cap K^T$ and $M \mapsto M \cap K^S$ preserve residue fields. That is, the place $\zeta$ is a lattice-isomorphism between $|K^V |K^S|$ and $|\zeta K |K|$. 

Proof. We need only check that the map $M \mapsto M \cdot K^S$ of $|K^T|K^Z|$ onto $|K^V |K^S|$ preserves residue fields, as its inverse clearly does. Given $M \in |K^T|K^Z|$, $M$ is $K^S$-determinable by Corollary (4.10), so by Proposition (4.3), $M = M \cdot K^S \cap M \cdot K^T = M \cdot K^S \cap K^T$ which has residue field $\zeta (M \cdot K^S)$.  

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Remark (4.18). By Corollary (4.17) we know that for any member \( L \) of \( \{ K^V | K \} \), \( \zeta((L \cap K^S) \cdot K^S) = \zeta L \). We remark that, analogous to Theorem (4.7) we have: \( L \) is \( K^S \)-determinable if and only if \( \zeta(L \cdot K^S) = \zeta L \). For, if \( L \) is \( K^S \)-determinable then \( \zeta(L \cdot K^S) = \zeta(L \cdot K^S \cap L^T) \) by (2.2) and

\[
\zeta(L \cdot K^S \cap L^T) = \zeta(L \cdot K^S \cap L \cdot K^T) = \zeta L.
\]

Conversely, if \( \zeta(L \cdot K^S) = \zeta L \) then \( L \cdot K^S \cap L \cdot K^T = L \cdot K^S \cap L^T \) which is the unique member of \( \{ L^T | L \} \) having residue field \( \zeta(L \cdot K^S) = \zeta L \), so \( L \cdot K^S \cap L \cdot K^T = L \).

Remark (4.19). We observe that for each \( K^S \), every member \( L \) of \( \{ K^V | K \} \) lies between two \( K^S \)-determinable fields which coincide in case \( L \) is \( K^S \)-determinable. Namely, \( (L \cap K^S) \cdot (L \cap K^T) \subseteq L \subseteq L \cdot K^S \cap L \cdot K^T \). The smaller field has value group \( \Gamma(L \cap K^S) \) and residue field \( \zeta L \); \( L \) is of degree \( \langle \Gamma L : \Gamma(L \cap K^S) \rangle \) over it. The larger field has value group \( \Gamma L \) and residue field \( \zeta(L \cdot K^S) \) and is of degree \( \langle \zeta(L \cdot K^S) : \zeta L \rangle \) over \( L \).

5. Let \( K^S \) be a fixed Neukirch complement for \( K^T \) in \( K^V \) with Galois group \( G^S = \text{Aut}(K^V | K^S) \) and splitting map \( \eta: \text{Aut}(K^V | K) / \text{Aut}(K^V | K^T) \to G^S \). We denote \( \text{Aut}(K^V | K^T) \) by \( G^T \). We regard \( \text{Aut}(K^V | K) \) as the semidirect product \( G^T \times \psi G^S \), where the action \( \psi \) of \( G^S \) on \( G^T \) is induced by inner automorphisms of \( \text{Aut}(K^V | K) \) acting on its abelian normal subgroup \( G^T \).

If \( K^{S'} \) is another Neukirch complement for \( K^T \) in \( K^V \) with splitting map \( \eta' \), consider \( \eta' \) as an isomorphism of \( \text{Aut}(K^V | K) / \text{Aut}(K^V | K^T) \to G^S \). We have, for any \( x \in G^S \), \( \eta'(jx) = (\phi_{\eta'}(x), x) \) for some \( \phi_{\eta'}(x) \in G^T \). Simple computation shows that the map \( \phi_{\eta'} : G^S \to G^T \) is a crossed homomorphism:

\[
(\phi_{\eta'}(xy), xy) = \eta'(j(xy)) = \eta'(jx) \cdot \eta'(jy)
\]

\[
= (\phi_{\eta'}(x), x)(\phi_{\eta'}(y), y) = (\phi_{\eta'}(x) \cdot [\phi_{\eta'}(y)]^x, xy).
\]

Here we denote the action \( (\psi x)(z) \) by \( z^x \). If \( K^{S'} = K^S \) then \( \phi_{\eta'} \) is the trivial crossed homomorphism \( \phi_{\eta'}(x) = 1 \) for all \( x \in G^S \).

It is clear that if \( \phi_{\eta'} = \phi_{\eta''} \) then \( \eta' = \eta'' \). Thus the map \( \eta' \mapsto \phi_{\eta'} \) is an injection of the set of splittings of sequence (3.1) into the group of crossed homomorphisms of \( G^S \) into \( G^T \).

A principal crossed homomorphism \( f \) of \( G^S \) into \( G^T \) is by definition one for which \( f(x) = \sigma \cdot (\sigma^x)^{-1} \) for some \( \sigma \in G^T \); we will denote by \( f_{\sigma} \) the principal crossed homomorphism determined by \( \sigma \).

Lemma (5.1). If \( K^S \) and \( K^{S'} \) are \( K \)-isomorphic, then they are \( K^T \)-isomorphic.
Proof. Say $K^S' = \sigma K^S$ for some $\sigma \in \text{Aut}(K^V|K)$. Then $\sigma$ is uniquely expressible as $r \cdot \mu$ for some $r \in \text{Aut}(K^V|K^T)$ and $\mu \in \text{Aut}(K^V|K^S)$, and we have $K^S' = r \cdot \mu \cdot K^S = r K^S$, as $\mu$ leaves $K^S$ fixed.

Proposition (5.2). If $K^S$ and $K^S'$, with splitting maps $\eta$ and $\eta'$ respectively, are $K$-isomorphic, then $\phi_{\eta'} \cdot \phi_{\eta}^{-1}$ is a principal crossed homomorphism.

Proof. We have $K^S' = \sigma K^S$ for some $\sigma \in \text{Aut}(K^V|K^T)$ and $\eta'(x) = \sigma \cdot \eta(x) \cdot \sigma^{-1}$ for all $x \in \text{Aut}(K^V|K)/\text{Aut}(K^V|K^T)$. Computing $\phi_{\eta'}$, we have

$$(\phi_{\eta'}, x, y) = \eta'(jx) = (\sigma, 1) \cdot (\eta(j(x))) \cdot (\sigma, 1)^{-1} = (\sigma, 1) \cdot (\phi_{\eta}(x), x) \cdot (\sigma^{-1}, 1)$$

so $\phi_{\eta'}(x) = \sigma \cdot \phi_{\eta}(x) \cdot (\sigma^{-1})^x = \phi_{\eta}(x) \cdot \sigma \cdot (\sigma^x)^{-1} = \phi_{\eta}(x) \cdot \sigma$ since $\text{Aut}(K^V|K^T)$ is abelian. Hence $(\phi_{\eta'}, \phi_{\eta}^{-1})(x) = \sigma \cdot (\sigma^x)^{-1} = f_\sigma(x)$, so $\phi_{\eta'} \cdot \phi_{\eta}^{-1} = f_\sigma$.

As the first cohomology group of $\text{Aut}(K^V|K^S)$ with coefficients in $\text{Aut}(K^V|K^T)$ is the quotient of the group of crossed homomorphisms of $\text{Aut}(K^V|K^S)$ into $\text{Aut}(K^V|K^T)$ by the subgroup of principal crossed homomorphisms (see [9, Chapter IV, §2]), we have

Proposition (5.3). The set of $K$-isomorphism classes of Neukirch complements for $K^S$ in $K^V$ is in bijective correspondence with a subset of the group $H^1(\text{Aut}(K^V|K^S), \text{Aut}(K^V|K^T))$ for any fixed Neukirch complement $K^S$.

Theorem (5.4). Let $K^S$ be a Neukirch complement for $K^T$ in $K^V$. For a given prescription $(\Delta, \mathcal{L})$ of value group extension and residue field extension, with $\Delta \in \{\Gamma K^V|K^T \}$ and $\mathcal{L} \in \mathcal{L} \cap \mathcal{K}$, there are at most $\text{card}(H^1(\text{Aut}(K^V|K^S), \text{Aut}(K^V|K^T)))$ non-$K$-isomorphic Neukirch-determinable extensions of $K$ having the prescribed value group and residue field.

Proof. Given $\Delta$ and $\mathcal{L}$, we know by Remark (4.14) that there is for each Neukirch complement $K^S$ exactly one $K^S$-determinable extension of $K$ in $K^V$ realizing $(\Delta, \mathcal{L})$. We verify that if $K^S$ and $K^S'$ are $K$-isomorphic then so are the extensions $L$ and $L'$ which they determine having value group $\Delta$ and residue field $\mathcal{L}$. We assume therefore that $K^S' = \sigma K^S$ for some $\sigma \in \text{Aut}(K^V|K)$, and as before, may take $\sigma \in \text{Aut}(K^V|K^T)$. Consider the field $\sigma L$. As $\nu$ is henselian, $\nu = \nu \cdot \sigma$ on any member of $\{K^V|K^T\}$, so $\Gamma(\sigma L) = \Gamma L = \Gamma(L \cap K^S) = \Gamma(\sigma(L \cap K^S)) = \Gamma(\sigma L \cap K^S)$, establishing that $\sigma L$ is $\sigma K^S$-determinable and has value group $\Gamma L$. Also, the residue field of $\sigma L$ is that of $\sigma L \cap K^T$, and as $\sigma$ leaves $K^T$ fixed, $\sigma L \cap K^T = \sigma L \cap \sigma K^T = \sigma(L \cap K^T) = L \cap K^T$ which has residue field $\mathcal{L}$. Thus
$\sigma L$ is $\sigma K^S$-determinable and has value group $\Delta$ and residue field $\mathcal{Q}$, so $\sigma L = L'$ by Remark (4.12).

6. Remarks. The author has not succeeded in finding an explicitly non-Neukirch-determinable field. However, since the two extensions $Q_2(\sqrt{2})$ and $Q_2(\sqrt{6})$ of the field $Q_2$ of 2-adic numbers are non-$Q_2$-isomorphic yet have the same value group and residue field, it is clear that for any Neukirch complement $Q_2^S$ for $Q_2^T$ in $Q_2^V$, not both $Q_2(\sqrt{2})$ and $Q_2(\sqrt{6})$ are $Q_2^S$-determinable. Indeed, either one of $Q_2(\sqrt{2}), Q_2(\sqrt{6})$ fails entirely to be Neukirch-determinable, or there are non-$Q_2$-isomorphic Neukirch complements for $Q_2^T$ in $Q_2^V$.

While Neukirch complements are necessarily minimal elements of $\{K^V|K\}$ with respect to having value group $\Gamma K^V$, the author has been unable to decide whether such a minimal element must be a Neukirch complement. An example of a non-Neukirch-determinable member of $\{K^V|K\}$ having value group $\Gamma K^V$ would establish the answer negatively. Indeed, if $L \in \{K^V|K\}$ has value group $\Gamma K^V$, then $L$ contains a minimal element of $\{K^V|K\}$ having that property, yet should $L$ contain any Neukirch complement $K^S$, then $L$ would be $K^S$-determinable, by Corollary (4.5).
