ON SYMMETRICALLY DISTRIBUTED RANDOM MEASURES(1)

BY

OLAV KALLENBERG

ABSTRACT. A random measure $\xi$ defined on some measurable space $(S, \mathcal{S})$ is said to be symmetrically distributed with respect to some fixed measure $\omega$ on $S$, if the distribution of $(\xi A_1, \cdots, \xi A_k)$ for $k \in \mathbb{N}$ and disjoint $A_1, \cdots, A_k \in \mathcal{S}$ only depends on $(\omega A_1, \cdots, \omega A_k)$. The first purpose of the present paper is to extend to such random measures (and then even improve) the results on convergence in distribution and almost surely, previously given for random processes on the line with interchangeable increments, and further to give a new proof of the basic canonical representation. The second purpose is to extend a well-known theorem of Slivnyak by proving that the symmetrically distributed random measures may be characterized by a simple invariance property of the corresponding Palm distributions.

1. Introduction. Let $S$ be a locally compact second countable Hausdorff space and let $\mathcal{B}$ be the ring of bounded Borel sets in $S$. Write $M(S)$ for the space of Radon measures on $(S, \mathcal{B})$, endowed with the vague or weak topology [7], and let $N(S)$ be the subspace of $\mathbb{Z}^+$-valued measures. Given any fixed $\omega \in M(S)$, we say that a random measure or point process $\xi$ on $S$ (i.e. a random element in $M(S)$ or $N(S)$ respectively [2], [5]) is symmetrically distributed with respect to $\omega$ [6], if for $k \in \mathbb{N}$ and disjoint $A_1, \cdots, A_k \in \mathcal{B}$ the distribution of $(\xi A_1, \cdots, \xi A_k)$ only depends on $(\omega A_1, \cdots, \omega A_k)$. As shown in [5], a simple point process $\xi$ is symmetrically distributed with respect to some diffuse (nonatomic) measure $\omega$ iff $\xi$ is a mixed Poisson or sample process. In case of random measures and diffuse $\omega$ with $\omega S < \infty$, a canonical representation was given in [6] in terms of a random variable $\alpha \geq 0$, prescribing the total diffuse mass of $\xi$, and a canonical point process on $R_+^* = (0, \infty)$, whose atom positions prescribe the atom sizes of $\xi$.

In the particular case when $S$ is a real interval and $\omega$ is Lebesgue measure, $\xi$ is seen to be symmetrically distributed with respect to $\omega$ iff the corresponding cumulative random process has interchangeable increments, so in this case the

theory of [7] and [8] applies. However, a direct extension of the results there to more general spaces is certainly not easy (cf. [6]). Furthermore, certain substantial improvements are obtainable in the present case, similar to those attained in [5, Theorem 3.1], when specializing the central limit theorem to nonnegative random variables. Finally, the present more general framework suggests some interesting generalizations which seem rather artificial on the line. For these three reasons, the theory of weak and strong convergence deserves its own treatment for random measures being given here in §2, along with a new proof of the canonical representation from [6].

In §3, we extend a result by Slivnyak [13], Papangelou [10] and myself [5, Theorem 5.3], by showing that the class of symmetrically distributed random measures may be characterized by a simple invariance property of the corresponding Palm distributions [4], [5]. Furthermore, it will be shown that a natural strengthening of this invariance condition will essentially delimit the class of symmetrically distributed random measures with symmetrically distributed canonical point processes (containing in particular all homogeneous (with respect to \( \omega \)) random measures with independent increments). Extensions of Slivnyak’s theorem in an entirely different direction have been given by Kerstan, Kummer and Matthes (see [9]).

Paralleling the exposition in [7], we shall now introduce four types of symmetrically distributed random measures on \( S \). Type I random measures are by definition of the form

\[
\xi = \sum_{j=1}^{k} \eta_j \delta_{\tau_j},
\]

where \( k \in \mathbb{N}, t_1, \ldots, t_k \in S, \) and the \( \eta_j \) are interchangeable random variables in \( R_+ \) with canonical point process \( \pi = \sum_j \delta_{\eta_j} \) [7]. Here \( \delta_s \in \mathcal{M}(S) \) is the measure with a unit atom at \( s \in S \). Type II random measures are also given by (1.1), but with \( k = \infty \). We then suppose that \( \{\tau_j\} \) has no limit point in \( S \) and that \( \eta_1, \eta_2, \ldots \) are interchangeable random variables in \( R_+ \) with canonical random measure \( \mu \), i.e. given \( \mu \), the \( \eta_j \) are conditionally independent with common distribution \( \mu \) (cf. [7, Theorem 1.1]). In both cases we put \( \nu = \sum \delta_{\tau_j} \). Type III random measures are given by

\[
\xi = \sum_{j=1}^{\infty} \beta_j \delta_{\tau_j}
\]

for arbitrary \( \omega \in \mathcal{M}(S) \) with \( \omega S = 1 \), independent random elements \( \tau_1, \tau_2, \ldots \) in \( S \) with common distribution \( \omega \), and random variables \( \alpha \geq 0, \beta_1 \geq \beta_2 \geq \cdots \geq 0 \) independent of \( \{\tau_j\} \) with \( \sum \beta_j < \infty \). The associated canonical point process on \( R_+^\prime \) is \( \beta = \sum \beta_j \delta_{\beta_j} \). Finally, the distribution of a Type IV random
measure is defined by the conditional L-transform \((L = \text{Laplace})\), given for measurable\(^{(2)}\) \(f: S \rightarrow R_+\) by

\[
-\log E(e^{-\xi f}|\gamma, \lambda) = \gamma \omega f + \int_S \int_{R'_+} (1 - e^{-xf(s)})\lambda(dx)\omega(ds) \quad \text{a.s.},
\]

where \(\omega \in M(S)\) while \(\gamma\) is an \(R_+\)-valued random variable and \(\lambda\) is a random measure on \(R'_+\) with \(\int (1 - e^{-x})\lambda(dx) < \infty\) a.s. This means that \(\xi\) has conditionally homogeneous (with respect to \(\omega\)) independent increments (cf. Lemma 3.1 in \([5]\)). The canonical quantities \((\nu, \pi), (\nu, \mu), (\omega, \alpha, \beta)\) and \((\omega, \gamma, \lambda)\), which clearly determine the distributions of the corresponding \(\xi\), will always be defined as above, with the same affixes as \(\xi\) if any.

For convenience, we introduce some further notation. For any function \(f\) and measure \(m\) on \(S\), we write \((fm)(dx) = f(x)m(dx)\) and \(mf = \int_S f(x)m(dx)\), and for measures \(m\) on \(R_+\) we define \(m^k(dx) = x^km(dx), k \in N\). The letter \(g\) is reserved for the function \(g(x) = (1 + x)^{-1}\). Equality and convergence in distribution \([2]\) will be denoted by \(\rightarrow d\) and \(\rightarrow\) respectively. We further write \(\rightarrow v\) and \(\rightarrow w\) for vague and weak convergence of measures \([7]\), and to distinguish between the corresponding notions of convergence in distribution, we use the symbols \(\rightarrow w d\) and \(\rightarrow w d\). For \(\alpha, \beta, \gamma, \) and \(\lambda\) as above, we often abbreviate \(\alpha \delta_0 + \beta^1\) by \(B\) and \(\gamma \delta_0 + \lambda^1\) by \(\Lambda\). (Note that the present use of \(\alpha, B\) and \(\Lambda\) differs from that in \([7], [8]\).) Finally, \(|A|\) denotes the diameter of \(A \in B\) in any fixed metric generating the topology of \(S\).

2. Convergence and related topics. In the following theorem we give extensions and partial improvements of the criteria for convergence in distribution, given for random processes with interchangeable increments in \([7, \text{Theorems 2.2, 2.3, 4.1, 3.2, 4.2 and 3.3]}\).

**Theorem 1.** If, for \(\xi_n\) of Type

(2.1) \(I: \nu_nS \rightarrow \infty, \nu_n/\nu_nS \rightarrow w \omega, \pi_n^1 \rightarrow w d B,\)

(2.2) \(III: \omega_n \rightarrow \omega, B_n \rightarrow w d B,\)

for some \(\omega\) and \(B\), then \(B\) may be written \(B = \alpha \delta_0 + \beta^1\), and \(\xi_n \rightarrow w d \xi\) where \(\xi\) is of Type III with canonical quantities \((\omega, \alpha, \beta)\). On the other hand, if for some \(\{r_n\}\) and/or \(\{c_n\}\) and for \(\xi_n\) of Type

(2.3) \(I: \left\{r_n \rightarrow \infty, c_n = r_n/\nu_nS \rightarrow 0\right\}, \nu_n/r_n \rightarrow \omega, c_ng \pi_n^1 \rightarrow w d g\Lambda,\)

\(\left(2\right)\) This obvious attribute will be suppressed in the sequel.
(2.4) II: \( r_n \to \infty, \quad \nu_n/r_n \to \omega, \quad r_n g_{\mu_n}^1 \xrightarrow{wd} g\Lambda, \)

(2.5) III: \( c_n \to 0, \quad \omega_n/c_n \to \omega, \quad c_n g_{B_n} \xrightarrow{wd} g\Lambda, \)

(2.6) IV: \( \omega_n/c_n \to \omega, \quad c_n g_{\Lambda_n} \xrightarrow{wd} g\Lambda, \)

for some \( \omega \) with \( \omega S = \infty \) and some \( \Lambda \), then, writing \( \Lambda = \gamma \delta_0 + \lambda^1 \), we have \( \xi_n \xrightarrow{vd} \xi \) where \( \xi \) is of Type IV with canonical quantities \( (\omega, \gamma, \lambda) \).

Conversely, if the \( \xi_n \) are of Type I or III and \( \xi_n \xrightarrow{wd} \) some \( \xi \) without fixed atoms and with \( P\{\xi \neq 0\} > 0 \), then \( \xi \) is of Type III and (2.1) or (2.2) holds respectively, while if the \( \xi_n \) are of Type I, II, III or IV and \( \xi_n \xrightarrow{vd} \) some \( \xi \) without fixed atoms and with \( P\{\xi S = \infty\} > 0 \), then \( \xi \) is of Type IV and (2.3), (2.4), (2.5) or (2.6) holds respectively for some \( \{r_n\} \) and/or \( \{c_n\} \).

Note that pleasant criteria for convergence towards mixed Poisson and sample processes may be obtained by specializing to point processes. In particular, Theorem 3 of Benczur [1] follows by combination with Theorem 5.2 in [5].

**Proof.** The sufficiency part will only be proved in the case I \( \to \) III, the remaining cases being similar, so suppose that (2.1) holds. For \( n \in \mathbb{N} \), let \( \eta_{n_1}, \ldots, \eta_{n_k_n} \) be the atom positions of \( \pi_n \) taken in random order, and let us first assume the \( \pi_n \) to be nonrandom. From (2.1) we get \( \pi_n^1 R \to BR \), so in particular the \( \eta_{n_j} \) are uniformly bounded, and we may thus conclude that \( \pi_n^2 \xrightarrow{wd} \beta^2 \) (cf. Theorem 5.2 in [2]). By Theorem 5.1 in [2], these results extend to random \( \pi_n \), in the sense that

\[
(\pi_n^1 R, \pi_n^2) \xrightarrow{wd} (BR, \beta^2) \quad \text{in} \quad R_+ \times M(R_+).
\]

Now define the random processes \( X_n \) in \( D[0, 1] \) by

\[
X_n(t) = \sum_{j \leq k_n} \eta_{nj}, \quad t \in [0, 1], \quad n \in \mathbb{N},
\]

and let \( X \) be a random process in \( D[0, 1] \) with \( X(0) \equiv 0 \) and with interchangeable increments, possessing canonical random elements \( BR, 0, \beta \), in the sense of [7]. By Theorem 2.2 in [7], (2.7) yields \( X_n \xrightarrow{d} X \) in the Skorohod \( J_1 \) topology [2]. Considering arbitrary \( m \in \mathbb{N} \) and \( A_1, \ldots, A_m \in \mathcal{B} \) with \( A_1 \subset \cdots \subset A_m \) and \( \omega A_j = 0, \ j = 1, \ldots, m \), we get by (2.1) \( \nu_n A_j/k_n \to \omega A_j, \ j = 1, \ldots, m \), so

\[
(X_n(\nu_n A_1/k_n), \ldots, X_n(\nu_n A_m/k_n)) \xrightarrow{d} (X(\omega A_1), \ldots, X(\omega A_m))
\]

in \( R_+^m \) by Theorem 5.5 in [2], since \( X \) has no fixed jumps [7]. But by interchangeability, this is equivalent to

\[
(\xi_n A_1, \ldots, \xi_n A_m) \xrightarrow{d} (\xi A_1, \ldots, \xi A_m).
\]
Taking differences, it is seen that (2.8) remains true even without the restriction $A_1 \subset \cdots \subset A_m$, and since the class $\mathcal{U} = \{A \in \mathcal{B}: \omega \partial A = 0\}$ is clearly a DC-ring in the sense of [5], satisfying $\xi \partial A = 0$ a.s. for any $A \in \mathcal{U}$, Theorem 1.1 in [5] yields $\xi_n \xrightarrow{ud} \xi$. Finally by (2.7), $\xi_nS = \pi_n^1R \xrightarrow{d} BR = \xi_S$, and $\xi_n \xrightarrow{wd} \xi$ follows as asserted.

Conversely, suppose that the $\xi_n$ are of Type I and that $\xi_n \xrightarrow{wd}$ some $\xi$ with

\[(2.9) \quad \xi\{s\} = 0 \text{ a.s., } s \in \mathcal{S}; \quad P\{\xi \neq 0\} > 0.\]

Then $\pi_n^1R = \xi_nS \xrightarrow{d} \xi_S < \infty$ a.s., so $\{(\pi_n^1R, \pi_n^1)\}$ is vaguely tight in $R_+ \times M(R_+)$, and hence by Theorem 5.1 in [2] and the point process nature of the $\pi_n$, $\{\pi_n^1\}$ is even weakly tight. Furthermore, $\{\nu_n/\nu_nS\}$ is automatically weakly relatively compact in $M(\overline{\mathcal{S}})$, (the bar for one-point compactification). It follows that any sequence $N' \subset N$ must contain some subsequence $N''$ satisfying the conditions

\[(2.10) \quad \pi_n^1 \xrightarrow{wd} \text{ some } B \text{ in } M(R_+), \quad n \in N'';\]
\[(2.11) \quad \nu_n/\nu_nS \xrightarrow{w} \text{ some } \omega \text{ in } M(\overline{\mathcal{S}}), \quad n \in N''.\]

To prove that

\[(2.12) \quad \nu_nS \xrightarrow{\infty} n \in N'',\]

suppose on the contrary that $\sup \{\nu_nS: n \in N''\} < \infty$ for some sequence $N''' \subset N''$. If the set of all $\nu_n$-atoms corresponding to $n$ in $N'''$ had no limit point in $\mathcal{S}$, we would get $\xi_n \xrightarrow{ud} 0 \xrightarrow{d} \xi$ contrary to (2.9), so we may assume the existence of some converging sequence $\{s_n\} \subset \mathcal{S}$ with $\nu_n\{s_n\} \geq 1$, $n \in N'''$. But since $\xi_n\{s_n\} \xrightarrow{d} 0$ by (2.9), we may conclude from interchangeability that $\xi_nS \xrightarrow{d} 0 = \xi_S$, again contradicting (2.9). This proves (2.12). By the sufficiency of (2.1), we now obtain from (2.10)—(2.12)

\[(2.13) \quad \xi_n \xrightarrow{wd} \xi \text{ in } M(\overline{\mathcal{S}}), \quad n \in N'',\]

where $\xi$ is a random measure in $\overline{\mathcal{S}}$ of Type III and with canonical quantities $\omega, \alpha, \beta$. But (2.13) implies both $\xi_nS \xrightarrow{d} \xi_S \xrightarrow{d} \xi_S$ and $\xi_nS = \xi_n\overline{\mathcal{S}} \xrightarrow{d} \xi(\overline{\mathcal{S}})$, and hence by combination $\xi_S \xrightarrow{d} \xi(\overline{\mathcal{S}})$, so e.g. by considering the expectation of $e^{-\xi_S} - e^{-\xi(\overline{\mathcal{S}})} \geq 0$, we get $\xi(\overline{\mathcal{S}}) = 0$ a.s., and finally $\omega(\overline{\mathcal{S}}) = 0$. It follows that (2.11) is also true in $M(\mathcal{S})$, and that $\xi$ (\xrightarrow{d} \xi on $\mathcal{S}$) is of Type III with the same canonical quantities. Furthermore, $\omega$ must be diffuse by (2.9), and so $\omega, \alpha$ and $\beta$ are a.s. uniquely determined by the diffuse component and the atom sizes and positions of $\xi$. The proof of (2.1) may now be completed by applying Theorem 2.3 in [2]. A similar argument proves the necessity of (2.2).
We next consider the necessity of (2.4) when the $\xi_n$ are of Type II and $\xi_n \overset{vd}{\rightarrow}$ some $\xi$ without fixed atoms and with $P\{\xi S = \infty\} > 0$. Choosing compact sets $C_j \uparrow S$ with $C_j \subset C_{j+1}$, $P\{\xi C_j > 0\} > 0$ and $\xi d C_j = 0$ a.s., $j \in \mathbb{N}$, we get $\xi_n \overset{vd}{\rightarrow} \xi$ in each $M(C_j)$, $j \in \mathbb{N}$, so by the necessity of (2.1), there exist diffuse measures $\omega_1, \omega_2, \ldots \in M(S)$ such that $\nu_n/\nu_n C_j \overset{w}{\rightarrow} \omega_j$ in $M(C_j)$, $j \in \mathbb{N}$. Furthermore, $r_n = \nu_n C_1 \rightarrow \infty$, and the restriction of $\xi$ to $C_j$ is symmetrically distributed with respect to $\omega_j$. In particular then $r_n/\nu_n C_j \rightarrow \omega_j C_1 \neq 0$, $j \in \mathbb{N}$, so

$$\frac{\nu_n}{r_n} = \left(\frac{\nu_n C_j}{r_n}\right) \overset{w}{\rightarrow} \omega_j C_1 \text{ in } M(C_j), \quad j \in \mathbb{N}. $$

Thus the measures $\omega_j/\omega_j C_1$, $j \in \mathbb{N}$, are all restrictions of some common diffuse measure $\omega \in M(S)$ such that $\nu_n/r_n \overset{v}{\rightarrow} \omega$ in $M(S)$. Moreover, $\xi$ is symmetrically distributed with respect to $\omega$, so we must have $\omega S = \infty$ since otherwise $\xi S < \infty$ a.s. Now let $A \in B$ be such that $\omega A > 1$ and $\omega \partial A = 0$. Then $\nu_n A/r_n \rightarrow \omega A > 1$, so for large $n$

$$\sum_{j < r_n} \eta_{nj} \leq \sum_{j < \nu_n A} \eta_{nj} \overset{d}{=} \varepsilon_n A \overset{d}{\rightarrow} \xi A \quad (2.14)$$

by interchangeability. This proves tightness in $R_+$ of the sequence of leftmost members in (2.14), and also, by interchangeability, of the sequence

$$\left(\sum_{j < r_n} \eta_{nj}, \sum_{j < 2r_n} \eta_{nj}, \ldots\right), \quad n \in \mathbb{N}, \quad (2.15)$$

of random elements in $R_+^\infty$. Hence, given any sequence $N' \subset N$, there exists some subsequence $N'' \subset N'$ for which (2.15) converges in distribution, and by Theorem 1.3 in [7] we get $\mu_n \overset{wr}{\rightarrow} \mu$, $n \in N''$. In the particular case of nonrandom $\mu_n$, it follows by Theorem 3.1 in [5] that $r_n \mu_n \overset{w}{\rightarrow} \omega A$, $n \in N''$, and this extends to general $\mu_n$ by randomization (cf. the proof of Theorem 3.2 in [7]). Hence (2.4) holds for $n \in N''$, and in particular it follows by the sufficiency part that $\xi$ is of Type IV with canonical quantities $\omega, \gamma, \lambda$. Proceeding as in the proof of Theorem 3.1 in [7], it is seen that $\gamma$ and $\lambda$ are unique, and so (2.4) holds for $n \in N$ by Theorem 2.3 in [2]. The necessity of (2.6) may be proved by similar arguments.

We finally consider the necessity of (2.3) when the $\xi_n$ are of Type I and $\xi_n \overset{vd}{\rightarrow}$ some $\xi$ without fixed atoms and with $P\{\xi S = \infty\} > 0$. Proceeding as above, we get $r_n = \nu_n C_1 \rightarrow \infty$, and further $\nu_n/r_n \overset{v}{\rightarrow}$ some $\omega$, where $\omega$ is diffuse with $\omega S = \infty$ and such that $\xi$ is symmetrically distributed with respect to $\omega$. Moreover,

$$\liminf_{n \to \infty} c_n^{-1} = \liminf_{n \to \infty} \nu_n S/r_n \geq \omega S = \infty.$$
If \( N' \) is an arbitrary subsequence of \( N \), it follows as before that (2.15) converges as \( n \rightarrow \infty \) through some \( N'' \subset N' \), and by comparison of Theorems 3.2 and 4.1 in [7], it is seen that this remains true with the \( \eta_{n_j} \) of (2.15) replaced by some \( \eta'_{n_j} \) which for fixed \( n \in N'' \) are interchangeable random variables with canonical random measure \( \mu_n = \pi_n / \nu_n S = c_n \pi_n / r_n \). Hence

\[
r_n \mu_n^1 = c_n g \mu_n^1 \xrightarrow{wd} \text{some } g \Lambda \text{ in } M(R_+), \quad n \in N''.
\]

The remainder of the proof is similar to that of (2.4). A similar argument proves the necessity of (2.5).

We shall now show how the canonical representations of symmetrically distributed random measures given in [6] for bounded \( \omega \) may be deduced from Theorem 1. (See also Theorem 5.1 in [5] and Theorems 2.1 and 3.1 in [7].)

**Corollary 1.** Let \( \xi \) be a random measure on \( S \) and let \( \omega \in M(S) \) be diffuse. Then \( \xi \) is symmetrically distributed with respect to \( \omega \) iff \( \xi \) is of Type III or IV (depending on whether \( \omega S < \infty \) or \( \omega S = \infty \)).

For later needs note in particular that the random measures of Type IV with \( \omega S < \infty \) form a subclass of those of Type III. This may also be proved directly from the definitions.

**Proof.** Assume that \( P\{\xi \neq 0\} > 0 \). We first consider bounded \( S \), in which case we may suppose that \( \omega S = 1 \). For each \( n \in N, \) divide \( S \) into finitely many disjoint sets \( I_{nj} \in B \) with \( \omega I_{nj} > 0 \) and \( \omega \partial I_{nj} = 0, \ j = 1, \cdots, k_n, \) and such that \( \{I_{n+1,j}^\prime\} \) is a refinement of \( \{I_{nj}\} \) for each \( n \) and \( \max |I_{nj}| \rightarrow 0 \). Put \( r_n = n/\min_j \omega I_{nj} \) and choose \( \nu_n = \Sigma_k \delta_{i n k} \in M(S) \) with \( \nu I_{nj} = [r_n \omega I_{nj}] \). An easy calculation yields

\[
1 - 1/n < \nu_n I_{nj}/r_n \omega I_{nj} < 1, \quad j = 1, \cdots, k_n, \ n \in N,
\]

which clearly remains true with \( I_{nj} \) replaced by any nonempty union \( U \) of sets among \( I_{n1}, \cdots, I_{nk_n} \). For such \( U, \)

\[
(2.16) \quad \left| \frac{\nu_n U}{\nu_n S} - \omega U \right| \leq 2 \left| \frac{\nu_n U - \nu_n S \omega U}{r_n \omega U} \right| \leq 2 \left| \frac{\nu_n U}{r_n \omega U} - 1 \right| + 2 \left| \frac{\nu_n S}{r_n \omega S} - 1 \right| < \frac{4}{n},
\]

and in particular, \( \nu_n / \nu_n S \xrightarrow{wd} \omega \). For \( n \in N, \) we next divide \( S \) into disjoint sets \( A_{nj} \in B \) with \( \omega A_{nj} = (\nu_n S)^{-1} \), \( j = 1, \cdots, \nu_n S, \) and put \( \xi_n = \Sigma_j \delta_{n j} \). Then the \( \xi_n \) are of Type I, and \( \xi_n \xrightarrow{wd} \xi \) follows from (2.16) by Theorem 1 in [5] and the easily verified fact that, for disjoint \( U_{n1}, \cdots, U_{nk}, \ n \in Z_+, \ (\omega U_{n1}, \cdots, \omega U_{nk}) \rightarrow (\omega U_{01}, \cdots, \omega U_{0k}) \) implies \( (\xi U_{n1}, \cdots, \xi U_{nk}) \xrightarrow{d} (\xi U_{01}, \cdots, \xi U_{0k}) \). (Use the symmetry of \( \xi \) and the fact that \( U_n \downarrow \emptyset \) implies \( \xi U_n \rightarrow 0 \) a.s.) We may now conclude from the converse part of
Theorem 1 that $\xi$ is of Type III. In the case of unbounded $S$, we may again use the converse part of Theorem 1, now with the $\xi_n$ chosen as restrictions of $\xi$ to some suitable sequence of bounded sets. For the applicability when $\omega S = \infty$, note that by Fatou's lemma, for disjoint $A_1, A_2, \cdots \in \mathcal{B}$ with $\omega A_k > 1$ and for sufficiently small $\epsilon > 0$,

$$P\{\xi S = \infty\} \geq P\{\xi A_k > \epsilon \text{ i.o.}\} \geq \limsup_{k \to \infty} P\{\xi A_k > \epsilon\} > 0.$$ 

In [7, Theorem 5.3], it was shown that the distribution of any random process with interchangeable increments is uniquely determined by that of its restriction to any fixed subinterval. Obviously, this result generalizes to the case of random measures, yielding alternative convergence criteria in Theorem 1. In the particular case of nonrandom canonical quantities (allowing interpretations in terms of sampling from finite populations), we may obtain still simpler determining (and therefore also convergence determining) classes [2, p. 15]. In fact, symmetrization in Lemma 11.2 by Rosen [12] (cf. Theorem 12.1 in [12] and Theorems 4–5 in [3]) yields the

**Proposition 1.** Let $\xi$ be a random measure on $S$ of Type III, and suppose that $B$ is nonrandom. If $\omega$ is known, then the distribution of $\xi$ is uniquely determined by that of $\xi A$ for any fixed $A \in \mathcal{B}$ with $0 < \omega A < \omega S$.

Note that the corresponding statement for Type IV random measures is also true. For simple point processes, we need not even assume $B$ (or $\Lambda$) to be nonrandom [5, Theorem 5.2].

We conclude this section by considering extensions and partial improvements of the variational and ergodic results given for random processes with interchangeable increments in [8, Theorems 5.1, 6.2, 6.3 and 6.4]. Clearly, $\Pi_n$ should now denote a partition of $S$ or of some $S_n \in \mathcal{B}$ into disjoint measurable sets $A_{n1}, \cdots, A_{nk}$. For any $m \in M(S)$, we write $\Pi_n m = \Sigma_k \delta_{m A_{nk}} \in M(R_+)$. In analogy with [8], we further define $|\Pi_n|_1 = \max j \omega A_{nj}$, $|\Pi_n|_2^2 = \Sigma_j (\omega A_{nj})^2 = (\Pi_n \omega)^2 R$, and we say that $\{\Pi_n\}$ is nested if it proceeds by successive refinements. For Type IV random measures with $\omega S = \infty$, $\mu_p$ denotes the canonical random measure corresponding to a partition of $S$ into sets of $\omega$-measure $p > 0$, while $B_n$ corresponds to the restriction of $\xi$ to $S_n \in \mathcal{B}$. Using these notations, we may state the strong counterpart of Theorem 1 as follows.

**Theorem 2.** If $\xi$ is a Type III random measure and if $\Pi_1, \Pi_2, \cdots$ are partitions of $S$ which are either nested with $|\Pi_n|_1 \to 0$ or satisfy $\Sigma_n |\Pi_n|_2^2 < \infty$, then

$$(\Pi_n \xi)^1 \overset{w}{\to} B \text{ a.s. in } M(R_+).$$
On the other hand, if \( \xi \) is of Type IV with \( \omega S = \infty \) then
\[
\frac{g_1^1}{p^1/p} \xrightarrow{w} gA \quad \text{as} \quad p \to 0, \quad \text{a.s. in} \quad M(R_+).
\]
Furthermore, for \( S_1 \subset S_2 \subset \cdots \in \mathcal{B} \) with \( \omega S_n \to \infty \), and for any \( f: R_+ \to R_+ \),
\[
\frac{fB_n/\omega S_n}{\omega S_n} \xrightarrow{w} fA \quad \text{in} \quad M(R_+), \quad \text{a.s. within} \quad \{\Lambda f < \infty\}.
\]
For such \( \{S_n\} \), let the \( \Pi_n \) be partitions of \( S_n, n \in N \), satisfying
\[
|\Pi_n|^2/\omega S_n \to 0, \quad \sum_n |\Pi_n|^2/(\omega S_n)^2 < \infty.
\]
Then
\[
g(\Pi_n \xi)^1/\omega S_n \xrightarrow{w} gA \quad \text{a.s. in} \quad M(R_+).
\]

It should be noticed that the monotonicity of \( \{S_n\} \) is essential for the truth of the statements involving (2.19) and (2.20). Similarly, the nestedness of \( \{\Pi_n\} \) is essential for the truth of (2.17) in the case \( |\Pi_n|_\infty \to 0 \). However, the nestedness can be dispensed with if we assume \( \omega \) to be diffuse and change the definition of \( |\Pi_n|_\infty \) to \( |\Pi_n|_\infty = \max_j |A_{nj}| \).

**Proof.** To prove the first assertion, we may clearly assume that \( B \) is nonrandom and that \( \omega S = 1 \). The probability that two particular atoms lie in the same set of \( \Pi_n \) is then \( |\Pi_n|^2 \leq |\Pi_n|_\infty \). If the \( \Pi_n \) are nested, then this event is nonincreasing in \( n \), so it can a.s. only occur finitely often provided \( |\Pi_n|_\infty \to 0 \). If \( \Sigma_n |\Pi_n|^2 < \infty \), the same statement follows by the Borel-Cantelli lemma.

The extension to any finite set of atoms being immediate, it follows easily that \( \Pi_n \xi \xrightarrow{w} \beta \) a.s. in \( M(R_+) \). Since \( (\Pi_n \xi)^1 R = BR \) holds identically, this completes the proof of (2.17). The assertion involving (2.18) is essentially equivalent to the converse part of Theorem 3.1 in [5]. The remainder of the proof is easy, given the exposition in [8].

3. Invariance of Palm distributions. In this section we shall show that the defining property of symmetrically distributed random measures is closely related to some other symmetry properties, expressible in terms of Palm distributions. Just as for point processes in [5], the latter are defined for arbitrary random measures \( \xi \) with \( E\xi \in M(S) \) as the distributions of random measures \( \xi_s, s \in S \), satisfying, for any \( f: M(S) \to R_+ \),
\[
Ef(\xi_s) = Ef(\xi)(ds)/E\xi(ds), \quad s \in S \quad \text{a.e.} \quad E\xi.
\]
(Cf. [4] for existence. For the related concept of Campbell measure, see [9].)

Following [5], we shall say that \( \xi \) is a *mixed Poisson process on \( S \), if there exist some \( R_+ \)-valued random variable \( \vartheta \) and some \( \omega \in M(S) \) such that,
given \( \theta, \xi \) is conditionally a Poisson process with intensity \( \theta \omega \). In this case

\[
P(\xi A = 0) = \phi(\omega A), \quad A \in \mathcal{B},
\]

where \( \phi \) is the \( L \)-transform of \( \theta \). On the other hand, \( \xi \) is a mixed sample process on \( S \), if there exist some \( \mathbb{Z}_+ \)-valued random variable \( k \) and some \( \omega \in \mathcal{M}(S) \) with \( 0 < \omega S < \infty \) such that, given \( k \), \( \xi \) is conditionally a sample process with intensity \( k \omega / \omega S \), i.e. \( \xi \) has conditionally \( k \) unit atoms whose positions are distributed as \( k \) independent random elements in \( S \) with common distribution \( \omega / \omega S \). Again (3.2) is true, but now \( \phi(t) = \psi(1 - t/\omega S) \) where \( \psi \) is the probability generating function of \( k \). In both cases the distribution of \( \xi \) is completely determined by \( \omega \) and \( \phi \), and we denote it for brevity by \( MP(\omega, \phi) \) or \( MS(\omega, \phi) \) respectively. For diffuse \( \omega \) it follows from Corollary 1 (cf. [5, Theorem 5.1]) that a simple point process \( \xi \) is symmetrically distributed with respect to \( \omega \) iff \( \xi \) is \( MP(\omega, \phi) \) or \( MS(\omega, \phi) \) for some \( \phi \).

In [5, Theorem 5.3] (cf. [10]), it was shown that, if \( \xi \) is a point process on \( S \) with \( \omega = E\xi \in \mathcal{M}(S) \), then the distribution of \( \xi_s - \delta_s \) is independent of \( s \) a.e. \( \omega \) iff \( \xi \) is \( MP(\omega, \phi) \) or \( MS(\omega, \phi) \), and in this case \( \xi_s - \delta_s \) is a.e. \( MP(\omega, -\phi') \) or \( MS(\omega, -\phi') \) respectively. In particular [5] (cf. [10], [4]), \( \xi_s - \delta_s \) is a Poisson process with intensity \( \omega \). We shall now extend these results to arbitrary random measures. Let us say that a measure is degenerate if its mass is confined to one single point.

**Theorem 3.** Let \( \xi \) be a random measure on \( S \) with \( E\xi \in \mathcal{M}(S) \). Then

\[
(\xi_s \{s\}, \xi_s - \xi_s \{s\} \delta_s) \overset{\text{d}}{=} (\eta, \xi) \text{ independently of } s \text{ a.e. } E\xi, \text{ iff } E\xi \text{ is diffuse (except possibly for a.s. degenerate } \xi \text{) and } \xi \text{ is symmetrically distributed with respect to } E\xi. \text{ In this case, } (\eta, \xi) \text{ is also symmetrically distributed}^{(3)} \text{ with respect to } E\xi, \text{ and furthermore, } \eta \text{ is independent of } \xi \text{ iff either}

(i) \( \xi \) is of Type III with \( \alpha = 0 \) a.s. and \( \beta \) a mixed sample process, or

(ii) \( \xi \) is of Type IV with \( \Lambda = \rho M \) a.s. for some random variable \( \rho \) and some nonrandom \( M \in \mathcal{M}(\mathbb{R}_+) \).

A very special case of the situation in (ii) was discussed by Port and Stone in [11, Example 2].

As will be seen from the proof, the distributions of \( \xi \) and \( (\eta, \xi) \) are related, in case of symmetry, by either or both of the relations

\[
Ef(\eta, B) = \frac{1}{EBR} E \int_R f(x, B - x\delta_x)B(dx),
\]

\[^{(3)} \] This means of course that the distribution of \( (\eta, \xi A_1, \cdots, \xi A_k) \) only depends on \( (E\xi A_1, \cdots, E\xi A_k) \).

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
symmetrically distributed random measures 115

\[ Ef(\eta, \hat{\Lambda}) = \frac{1}{E\Lambda R} \int_R f(x, \Lambda) \Lambda(dx), \]

for arbitrary \( f: R_+ \times M(R_+) \rightarrow R_+ \), where \( \hat{\Lambda} = \hat{\alpha}\delta_0 + \hat{\beta} I \) and \( \hat{\Lambda} \) denote the canonical random measures of \( \xi \). If \( \alpha = 0 \) and \( \beta \) is \( MS(E\beta, \phi) \), then \( \eta \) has distribution \( E\beta/E\beta R \), where \( \hat{\alpha} = 0 \) and \( \hat{\beta} \) is \( MS(E\beta, -\phi') \). On the other hand, if \( \Lambda = \rho M \) for some random variable \( \rho \geq 0 \) with \( L \)-transform \( \phi \) and some probability measure \( M \) on \( R_+ \), then \( \eta \) has distribution \( M \) while \( \Lambda = \rho M \) for some random variable \( \rho \geq 0 \) with \( L \)-transform \( -\phi' \).

We finally remark that the cases (i) and (ii) where \( \eta \) and \( \xi \) are independent are not so far apart as they may appear. In fact, as may be seen from Theorem 1 (or rather from its proof), the random measures satisfying (i) or (ii) constitute the closure with respect to convergence in distribution in the vague topology of the class of random measures satisfying (i).

For the proof of Theorem 3, we need a lemma of some independent interest.

**Lemma 1.** Let \( \xi \) be a random measure on \( S \) with \( \xi < \infty \) a.s. and let \( \tau \) be a random element in \( S \) which for given \( \xi \neq 0 \) has conditional distribution \( \xi/\xi \). Then \( \tau \) is conditionally independent of \( (\tilde{n}, \tilde{\xi}) = (\xi(\tau), \xi - \xi(\tau)\delta_\tau) \), given that \( \xi \neq 0 \), iff \( \xi \) is symmetrically distributed with respect to some diffuse (except possibly for a.s. degenerate \( \xi \)) \( \omega \in M(S) \). In this case, \( (\tilde{n}, \tilde{\xi}) \) is conditionally symmetrically distributed with respect to \( \omega \), and the canonical random measure \( \tilde{\Lambda} \) of \( \tilde{\xi} \) satisfies, for \( f: R_+ \times M(R_+) \rightarrow R_+ \),

\[ E[f(\tilde{n}, \tilde{\Lambda})|\xi \neq 0] = E\left[ \frac{1}{BR} \int_R f(x, B - x\delta_x)B(dx)|B \neq 0 \right]. \]

Note that, in the particular case of point processes, \( \tau \) is one of the atom positions chosen at random. Clearly the conditional distributions of \( \xi \), given \( \tau = s \), \( s \in S \) a.e. \( P_\tau^{-1} \), here play the role of the Palm distributions in Theorem 3. Though perhaps at least as natural from the point of view of applications, they do not behave quite as well mathematically. A related type of competitor to the Palm distributions was considered by Slivnyak [13] for stationary point processes.

**Proof of Lemma 1.** Suppose that \( \tau \) is conditionally independent of \( (\tilde{n}, \tilde{\xi}) \) with distribution \( \omega \), given the event \( \{\xi \neq 0\} \), i.e. that for \( f: S \rightarrow R_+ \)

\[ E[f(\tau)|\tilde{n}, \tilde{\xi}] = \omega f \quad \text{a.s. on} \quad \{\xi \neq 0\}. \]

Let \( \alpha \) be the total diffuse mass and \( \beta_1 \geq \beta_2 \geq \cdots \) the atom sizes of \( \xi \), and put \( \beta = \Sigma_1 \delta_{\beta_j} \), \( B = \alpha \delta_0 + \beta I \). Since \( (\tilde{n}, \tilde{\Lambda}) \) depends measurably on \( (\tilde{n}, \tilde{\xi}) \), it follows from (3.6) that

\[ E[f(\tau)|\tilde{n}, B] = \omega f \quad \text{a.s. on} \quad \{B \neq 0\}. \]
Now define $\tau_1, \tau_2, \cdots$ as the atom positions corresponding to $\beta_1, \beta_2, \cdots$, being taken in random order within sets of equal $\beta_j$. By definition of $\tau$ we have for $f: S \rightarrow R_+$

$$E[f(\tau)|\xi, \eta = \beta_1] = E[f(\tau_1)|\xi] \quad \text{a.s. on } \{\xi \neq 0\},$$

so for $f: S \times M(S) \rightarrow R_+$

$$E[f(\tau, \tilde{\eta})|\xi, \eta = \beta_1] = E[f(\tau_1, \xi - \beta_1 \delta_{\tau_1})|\xi] \quad \text{a.s. on } \{\xi \neq 0\},$$

and finally

$$E[f(\tau, \tilde{\eta})|B, \eta = \beta_1] = E[f(\tau_1, \xi - \beta_1 \delta_{\tau_1})|B] \quad \text{a.s. on } \{B \neq 0\}.$$ Combining this with (3.7) and writing $\xi_d$ for the diffuse component of $\xi$, it follows that $\tau_1$ is conditionally independent of $\xi - \beta_1 \delta_{\tau_1}$ and hence of $(\tau_2, \tau_3, \cdots; \xi_d)$ with distribution $\omega$, given $B$ with $B \neq 0$. Proceeding inductively, it is seen that, given $B$, the $\tau_j$ are conditionally independent of $\xi_d$ and mutually independent with common distribution $\omega$. For $f: S \rightarrow R_+$ we further obtain

$$E[f(\tau)|\xi, \eta = 0] = \xi_d f/\alpha \quad \text{a.s. on } \{\alpha \neq 0\},$$

and since $\xi_d$ depends measurably on $\tilde{\eta}$, it follows that

$$\omega f = E[f(\tau)|\tilde{\eta}, \eta = 0] = \xi_d f/\alpha \quad \text{a.s. on } \{\alpha \neq 0\},$$

proving that $\xi_d = \omega$ a.s. We may now conclude that, given $B$, $\xi$ is conditionally symmetrically distributed with respect to $\omega$, and this clearly remains true unconditionally. If $\omega\{s\} > 0$ for some $s \in S$, then $\alpha \omega$ cannot be diffuse unless $\alpha = 0$, and furthermore,

$$(\omega\{s\})^2 P\{\beta_2 > 0\} \leq P\{\tau_1 = \tau_2, \beta_2 > 0\} \leq P\{\beta_1 > \beta_1 + \beta_2, \beta_2 > 0\} = 0,$$

so $\beta_2 = 0$ a.s., and hence $\xi = \beta_1 \delta_{\tau_1}$.

Conversely, if $\xi$ is symmetrically distributed with respect to some diffuse $\omega \in M(S)$, it follows by Corollary 1 that, for given $(\tilde{\eta}, B) \neq 0$, $\tau$ is conditionally independent of $(\tilde{\eta}, \tilde{\xi})$ with distribution $\omega$, and this will clearly remain true unconditionally. Since, for given $B \neq 0$, $\tilde{\eta}$ has conditional distribution $B/BR$, (3.5) follows easily by the same corollary.

**Proof of Theorem 3.** Since forming the Palm distributions and restricting to a subspace are interchangeable operations, we may assume that $\xi S < \infty$ a.s. when proving the first assertion. Let $\tau$ be defined as in Lemma 1 and consider any $f: M(S) \times S \rightarrow R_+, u \in R_+$ and $s \in S$. By Proposition 2 in [4], which clearly carries over to arbitrary random measures,
$$E[f(\xi, \tau); \xi S \in du, \tau \in ds] = E[f(\xi, s)P\{\tau \in ds|\xi\}; \xi S \in du]$$

$$= E[f(\xi, s)\xi(ds)/u; \xi S \in du] = u^{-1}E[f(\xi_s, s); \xi_s S \in du]E(\xi(ds)),$$

so by the chain rule for Radon-Nikodym derivatives, for \((u, s) \in R_+ \times S\) a.e. \(E(\xi(ds)); \xi S \in du)\),

$$E[f(\xi, \tau)|\xi S = u, \tau = s] = \frac{E[f(\xi, \tau); \xi S \in du, \tau \in ds]}{P\{\xi S \in du, \tau \in ds\}}$$

$$= \frac{E[f(\xi_s, s); \xi_s S \in du]}{P\{\xi_s S \in du\}} = E[f(\xi_s, s)|\xi_s S = u].$$

(cf. Lemma 5.1 in [5]). In particular, this yields a.e., for \(f: R_+ \times M(S) \rightarrow R_+\),

$$E[f(\xi(\{s\}, \xi - \xi(\{s\})\delta_s)|\xi S = u, \tau = s]$$

$$= E[f(\xi_s(\{s\}), \xi_s - \xi_s(\{s\})\delta_s)|\xi_s S = u].$$

(3.8)

Now if the distribution of \((\xi_s(\{s\}), \xi_s - \xi_s(\{s\})\delta_s)\) is a.e. independent of \(s\), then so is the right-hand side of (3.8), and it follows that \((\xi(\{s\}), \xi - \xi(\{s\})\delta_s)\) is conditionally independent of \(\tau\), given \(\xi S = u\). Since conditioning on \(\xi S = u\) will not change the definition of \(\tau\) in terms of \(\xi\), Lemma 1 applies, and so we may conclude that \(\xi\) is conditionally symmetrically distributed with respect to some normalized diffuse (except possibly for a.s. degenerate \(\xi\) \(\omega_u \in M(S)\). But for any \(A \in B\) and \(u \in R_+\), by the assumed invariance,

$$E[\xi A; \xi S \in du] = \int_A P\{\xi_s S \in du\}E(\xi(ds)) = P\{\xi_s S \in du\}E(\xi A),$$

so by the chain rule

$$\omega_u A = \frac{1}{u}E[\xi A|\xi S = u] = \frac{E[\xi A; \xi S \in du]}{E[\xi S; \xi S \in du]} \frac{E[\xi S; \xi S \in du]}{uP\{\xi S \in du\}} = \frac{E[\xi A]}{E[\xi S]},$$

and we get \(\omega_u = E\xi/E\xi S\), independently of \(u > 0\) a.e. \(P(\xi S)^{-1}\), proving that \(\xi\) is even unconditionally symmetrically distributed.

Conversely, suppose that \(\xi\) is symmetrically distributed with canonical quantities \(\omega\) and \(B\), where \(\omega\) is diffuse and \(0 < EBR < \infty\). For \(f: R_+ \rightarrow R_+\), we get

$$E[\xi(ds)f(\xi S)] = E[E(\xi(ds)|BR)f(BR)] = E[BRf(BR)|\omega(ds)],$$

so by (3.1),

$$Ef(\xi_s S) = E[BRf(BR)]/EBR, \quad s \in S \text{ a.e. } E\xi.$$

(3.9)

Furthermore, by (3.8) and Lemma 1, the conditional distribution of \((\xi_s(\{s\}), \xi_s - \xi_s(\{s\})\delta_s)\), given \(\xi_s S\), is a.e. independent of \(s\), and this is also true for the un-
conditional distribution since by (3.9) the distribution of $\xi S$ is a.e. independent of $s$. From (3.8) it is further seen that $(\eta, \xi) \overset{d}{=} (\xi_s \{s\}, \xi_s - \xi_s \{s\} \delta_s)$ is symmetrically distributed with respect to $\omega$, and by combination of (3.5) and (3.8) we get for $f: R_+ \times M(R_+) \rightarrow R_+$

$$E[f(\eta, \bar{B})|\xi S = u] = \frac{1}{u} E \left[ \int_R f(x, B - x\delta_x)B(dx)|BR = u \right],$$

$u > 0$ a.e. $P(\xi S)^{-1}$,

which yields (3.3) when inserted in (3.9).

To prove (3.4) when $\xi$ is symmetrically distributed with canonical $\omega$ and $\Lambda$, $\omega S = \infty$, let $B$ and $\bar{B}$ correspond to the restrictions of $\xi$ and $\xi$ respectively to some $A \in B$ with $\omega A = t > 0$. If $A$ is nonrandom, we have $\alpha = ty$ while $\beta$ is a Poisson process with intensity $t \lambda \ [7]$, so by (3.1) and the fact that $\beta \overset{d}{=} \beta_x - \delta_x$, $x > 0$ a.e. $E\beta$, we get for $f: R_+ \times R_+ \times M(R_+) \rightarrow R_+$

$$E \int_R f(x, \alpha, \beta - \delta_x)B(dx) = E \int_R f(x, \alpha, \beta - \delta_x)\beta(dx) + E[\alpha f(0, \alpha, \beta)]$$

$$= \int_R Ef(x, \alpha, \beta_x - \delta_x)\lambda(dx) + E[t\gamma f(0, \alpha, \beta)]$$

$$= t \int_R Ef(x, \alpha, \beta)\lambda(dx) + tE[\gamma f(0, \alpha, \beta)]$$

$$= tE \int_R f(x, \alpha, \beta)\Lambda(dx),$$

and this result extends by conditioning to arbitrary $\Lambda$. Since $EBR = tE\Lambda R$, we get by (3.3) for $f: R_+ \times M(R_+) \rightarrow R_+$

(3.10) $$Ef(\eta, \bar{B}/t) = \frac{1}{E\Lambda R} E \int_R f(x, B/t)\Lambda(dx).$$

Letting $A \uparrow S$ we get by Theorem 2 $B/t \overset{v}{\rightarrow} \Lambda$ and $\bar{B}/t \overset{v}{\rightarrow} \hat{\Lambda}$ a.s. in $M(R_+)$, so for bounded and continuous $f$, (3.4) follows from (3.10) by repeated dominated convergence, and we may extend (3.4) successively, first by monotone convergence to indicators of open sets (cf. Theorem 1.2 in [2]), then by Dynkin’s theorem to arbitrary indicators, and finally by linearity and monotone convergence to arbitrary $f$.

Now suppose that $\eta$ and $\xi$ are independent. We may assume that $0 < E\xi S < \infty$, since otherwise the proof may be reduced to this case by restricting $\xi$ to bounded subspaces. In this case $\xi$ and $\xi$ are of Type III (and they may or may not be of Type IV, cf. the remark following Corollary 1). By (3.1) and (3.3) we get for any $t > 0$ and $f: M(R_+) \rightarrow R_+$
\[ Ee^{-nt} = E\left[ e^{-nt} f(B) \right] = \frac{1}{EB} \int_R e^{-xt} f(B - x\delta_x)B(dx) \]

\[ = \frac{1}{EB} \int_R e^{-xt} E[f(B - x\delta_x)EB(dx)], \]

so if \( 0 < Ef(B) < \infty \), we obtain

\[ Ee^{-nt} = \int_R e^{-xt} \frac{E[f(B - x\delta_x)]}{Ef(B)} \frac{EB(dx)}{EB}. \]

Comparing this with the formula obtained for \( f \equiv 1 \), it follows by the uniqueness theorem for \( L \)-transforms that \( Ef(B - x\delta_x) = Ef(B) \), \( x \geq 0 \) a.e. \( EB \). Turning to an \( f : R_+ \times \mathcal{N}(R_+) \rightarrow R_+ \) and using (3.1), we thus obtain for \( x > 0 \) a.e. \( EB \)

\[ (3.11) \quad Ef(\alpha, \beta) = \frac{E[B(dx)f(\alpha, \beta - \delta_x)]}{EB(dx)} = \frac{E[B(dx)f(\alpha, \beta - \delta_x)]}{EB(dx)} = Ef(\alpha_x, \beta_x - \delta_x) \]

(in an obvious notation), and also, provided \( E\alpha > 0 \),

\[ (3.12) \quad Ef(\alpha, \beta) = \frac{E[\alpha f(\alpha, \beta)]}{E\alpha}. \]

From now on, we may assume that \( E\beta R < \infty \), since otherwise we may consider the restrictions of \( \beta \) to compact subintervals of \( R_+ \). Proceeding as in the proof of Theorem 5.3 in [5], we may conclude from (3.11) that, for given \( \nu = \beta R \), \( \beta \) is conditionally a sample process independent of \( \alpha \) with intensity \( \nu E\beta/E\nu \). At this stage, we may assume that \( E\alpha \) and \( E\nu \) are both > 0, since otherwise either (i) or (ii) is trivially satisfied. If we can find a fixed \( c > 0 \) such that, given \( \alpha, \nu \) is conditionally Poissonian with mean \( c\alpha \), it will follow that \( \beta \) is conditionally a Poisson process with intensity \( c\alpha E\beta/E\nu \) (cf. Theorem 5.2 in [5]), and so \( \xi \) must be of Type IV with \( \gamma = \alpha/\omega S \) and \( \lambda = c\alpha(\omega SE\nu)^{-1}E\beta \), proving (ii).

To prove this assertion about \( \nu \), note that (3.11) and (3.12) imply for any \( t \geq 0 \) and \( s \in [0, 1] \)

\[ E[ae^{-\alpha ts^\nu}] = \frac{E[\beta(dx)e^{-\alpha ts^\nu - 1}]}{E\beta(dx)} = \frac{E[e^{-\alpha ts^\nu - 1}E[\beta(dx)|\alpha, \nu]]}{E\beta(dx)} = \frac{E[e^{-\alpha t s^\nu - 1}E[\beta(dx)]/E\nu]}{E\beta(dx)} = \frac{E[e^{-\alpha t s^\nu - 1}]}{E\nu}. \]
and hence by the uniqueness theorem,

\[
\frac{\alpha E[s^\nu | \alpha]}{E\alpha} = \frac{E[s^\nu \nu^{-1} | \alpha]}{E\nu} \quad \text{a.s., } 0 < s < 1. 
\]

Assuming these expectations to be calculated from some family of regular conditional distributions of \( \nu \), given \( \alpha \), (3.13) extends by continuity from any countable dense subset of \( s \)-values, so we may take the exceptional \( P \)-null set in (3.13) to be independent of \( s \). Writing \( \phi_\alpha(s) = E[s^\nu | \alpha] \) and \( c = E\nu/E\alpha \), we get a.s. the differential equations

\[
\phi'_\alpha(s) = c\phi_\alpha(s), \quad 0 < s < 1,
\]

and since \( \phi_\alpha(1) = 1 \) a.s., we obtain a.s. the unique solutions

\[
\phi_\alpha(s) = e^{-c\alpha(1-s)}, \quad 0 < s < 1,
\]

showing that the conditional distributions of \( \nu \), given \( \alpha \), are a.s. Poissonian with means \( c\alpha \). This proves the necessity of (i) and (ii).

Conversely, assuming \( \xi \) to be such as in (i), we get by (3.1), (3.3) and Theorem 5.3 in \([5]\), for any \( t \geq 0 \) and \( f: R^+ \to R^+ \),

\[
Ee^{-\eta t - \beta f} = \frac{1}{E\beta^1 R} \int_R e^{-xt} \exp[-(\beta - \delta_x)f] x\beta(dx)
\]

\[
= \frac{1}{E\beta^1 R} \int_R e^{-xt} E \exp[-(\beta_x - \delta_x)f] xE\beta(dx)
\]

\[
= E \exp[-(\beta_x - \delta_x)f] \int_R e^{-xt} \frac{E\beta^1(dx)}{E\beta^1 R},
\]

so \( \eta \) and \( \hat{\beta} \) are indeed independent with the asserted distributions. Similarly, for \( \xi \) as described in (ii), we get by (3.4) for any \( t \geq 0 \) and \( f: R^+ \to R^+ \)

\[
Ee^{-\eta t - \hat{\Lambda} f} = \frac{1}{E\rho MR} \int_R e^{-xt - \rho M f} \rho M(dx) = E[pe^{-\rho M f}] \int_R e^{-xt} M(dx),
\]

in conformity with our assertions. This completes the proof of Theorem 3.

It should be observed that, in the proof of the second assertion, the crucial point is to show \( \alpha \) must be a.s. zero if \( \xi \) is not of Type IV. In fact, assuming \( \xi \) to be of Type IV, (3.1) and (3.4) yield for any \( t \geq 0 \) and \( f: R^+ \to R^+ \)

\[
Ee^{-\eta t - \Lambda f} = \frac{1}{E\Lambda R} \int_R e^{-xt - \Lambda f} \Lambda(dx) = \int_R e^{-xt} E \exp[-\Lambda_x f] \frac{E\Lambda(dx)}{E\Lambda R},
\]
so if $\eta$ and $\xi$ are independent, it follows by the uniqueness theorem that $E \exp[-\Lambda_x f] = E e^{-\hat{\Lambda} f}$, $x \geq 0$ a.e. $E\Lambda$, and hence that $\Lambda_x \overset{d}{=} \hat{\Lambda}$ a.e. Arguing as in the proof of the first assertion in Theorem 3, it is not hard to see that this implies $\Lambda = \rho M$ for some random variable $\rho \geq 0$ and some nonrandom $M \in \mathcal{M}(\mathbb{R}_+)$.

ACKNOWLEDGEMENT. I wish to thank the referee for many useful comments.
