BRANCHING DEGREES ABOVE LOW DEGREES

BY

PETER A. FEJER

Abstract. In this paper, we investigate the location of the branching degrees within the recursively enumerable (r.e.) degrees. We show that there is a branching degree below any given nonzero r.e. degree and, using a new branching degree construction and a technique of Robinson, that there is a branching degree above any given low r.e. degree. Our results extend work of Shoenfield and Soare and Lachlan on the generalized nondiamond question and show that the branching degrees form an automorphism base for the r.e. degrees.

1. Introduction. In [1] we began a program of taking certain natural and important definable subclasses of the recursively enumerable (r.e.) degrees and studying their relation to the r.e. degrees as a whole. Our hope is that this program will tend to illuminate uniformities in the structure of the r.e. degrees, just as early work in the field (e.g. the Sacks’ Splitting and Density Theorems) did, rather than demonstrate pathological aspects of the structure.

In [1], the particular class of r.e. degrees considered was the nonbranching degrees. We were able to obtain a strong uniformity result there, namely, that the nonbranching degrees are dense in the r.e. degrees. In the present paper we consider the branching degrees, the class complementary to the nonbranching degrees, and give certain uniformity results concerning this class of degrees. The techniques involved are more complicated than those required in [1]. Before describing our results, we give the definition and discuss previous results concerning branching degrees.

Definition 1.1. An r.e. degree is branching if it is the infimum of two incomparable r.e. degrees.

As shown in [1], a result of Lachlan [2, Lemma 18] easily implies that in Definition 1.1 it does not matter if infima are taken with respect to all degrees or with respect to just the r.e. degrees.

The first result concerning branching degrees was the proof, obtained independently by Lachlan [2] and Yates [14], that 0 is a branching degree. (A pair of nonzero r.e. degrees which has infimum 0 is called a minimal pair.) This minimal pair result confirmed a conjecture of Sacks [6, p. 170, first ed.] and disproved a
conjecture of Shoenfield [7] that the r.e. degrees satisfy a certain homogeneity property. Lachlan, in the same paper [2], showed the existence of a nonzero branching degree. Later results on embedding lattices into the r.e. degrees involve constructions of branching degrees. For example, Thomason’s proof [13] that the countable atomless Boolean algebra can be embedded into the r.e. degrees is an extension of the techniques which Lachlan used to show the existence of a nonzero branching degree and this result shows that there are infinitely many branching degrees.

In §2 we show how Lachlan’s construction of a nonzero branching degree can be used to show that below any given nonzero r.e. degree there is a nonzero branching degree (Theorem 2.1). Further work with branching degrees seems to require more complicated branching degree constructions. In §3 we introduce the new branching degree construction which we need for later work by giving a new proof of the answer to the generalized nondiamond question which was first obtained by Shoenfield and Soare [9] and Lachlan [4] (Theorem 3.1). The construction involves a tree of strategies as used by Lachlan in [3, 4]. In §4 we illustrate a technique of Robinson for lifting a construction in the r.e. degrees above a given low r.e. degree by proving a special case of the Robinson Splitting Theorem [5, Corollary 9]. In §5 we combine techniques from §§3 and 4 to show that there is a branching degree above any given low r.e. degree. In fact, we show (Theorem 5.1) that the diamond lattice can be embedded into the r.e. degrees above any given low r.e. degree with top element preserved, thereby extending the result of Shoenfield and Soare and Lachlan mentioned above. Theorem 5.4 is a strengthened version of Theorem 5.1 which allows us to conclude that the branching degreees form an automorphism base for the r.e. degrees (Corollary 5.5) and that, given a nonzero, incomplete r.e. degree, there is a branching degree incomparable with the given r.e. degree (Corollary 5.6).

The question of density for the branching degrees is open as is the question of whether there is a branching degree above any given incomplete r.e. degree.\textsuperscript{2}

We now fix some notations and conventions which are used throughout the paper. A string is an element of \(2^{-\omega}\). If \(\sigma \in 2^n\) we call \(n\) the length of \(\sigma\) (lha = \(n\)). We write \(\subseteq\) for inclusion and \(\subset\) for strict inclusion. A set is often identified with its characteristic function, so if \(A\) is a set, \(A \upharpoonright n\) is a string of length \(n\) and if \(\sigma\) is a string, it makes sense to write \(\sigma \subseteq A\).

By degree we mean Turing degree. The least upper bound of two degrees \(a\) and \(b\) is called their join and is written \(a \cup b\); the greatest lower bound of \(a\) and \(b\), if it exists, is called their inf and is written \(a \cap b\).

Let \(\{W_e\}_{e \in \omega}\) be some standard enumeration of the r.e. sets and let \(\{W_{e,s}\}_{e,s \in \omega}\) be a recursive collection of finite sets such that for all \(e\) and \(s\), \(W_{e,s} \subseteq W_{e,s+1}\), and for all \(e\), \(W_e = \bigcup_s W_{e,s}\). In a construction involving \(W_e\), we assume that the elements of \(W_{e,s} - W_{e,s-1}\) are enumerated into \(W_e\) at the beginning of stage \(s\), before any action is taken for the construction. (Take \(W_{e,-1}\) to be \(\emptyset\).) If the construction involves a

\textsuperscript{2} Note added in proof. Theodore Slaman has recently informed us that, using the "monstrous" injury technique, he has now shown that the branching degrees are dense in the r.e. degrees.

given r.e. set $A$, then we assume an effective stage-by-stage enumeration of $A$ with new elements entering $A$ only at the beginning of each stage and only finitely many elements entering at any stage. Which effective enumeration of $A$ we use generally does not matter, but if we use in the construction of one-one effective enumeration $(a_n)_{n \in \omega}$ of $A$, then we assume that $a_s$ is the unique element which enters $A$ at stage $s$. Of course, if we are constructing the set $A$, then we may put new elements into $A$ at any time during a stage.

By a partial recursive functional $\Xi$ of $n$ set variables, we mean an r.e. set of axioms with no redundancy. An axiom consists of $n$ strings $\sigma_1, \ldots, \sigma_n$ of some common length $k$, an argument $x$, and a value $y$; we assume that $k > x$. If the axiom belongs to $\Xi$ and for each $i, 1 \leq i \leq n$, $\sigma_i \subseteq A_i$, then $\Xi(A_1, \ldots, A_n; x)$ converges to $y$. We use $\Xi(A_1, \ldots, A_n; x)$ to mean that $\Xi(A_1, \ldots, A_n; x)$ converges to some value. The length of an axiom is the common length of the strings $\sigma_i$. By “no redundancy” we mean that for any sets $A_1, \ldots, A_n$ and number $x$, at most one axiom in $\Xi$ applies to $A_1, \ldots, A_n$ and $x$. We always denote partial recursive functionals by capital Greek letters and their use functions by the corresponding small Greek letter. That is, if $\Xi(A_1, \ldots, A_n; x) \downarrow$, there is a unique axiom in $\Xi$ applying to $A_1, \ldots, A_n$ and $x$ and $\xi(A_1, \ldots, A_n; x)$ is the length of this axiom, which is $> x$. If $\Xi(A_1, \ldots, A_n; x)$ does not converge, then $\xi(A_1, \ldots, A_n; x) = 0$.

Let $(\Psi_{e,s})_{e,s \in \omega}$ and $(\Phi_{e,s})_{e,s \in \omega}$ be effective listings of all partial recursive functionals of one and two set variables respectively. Let $(\Psi_{e,s})_{e,s \in \omega}$ be a recursive double array of finite sets of axioms such that for all $e$ and $s$, each axiom in $\Psi_{e,s}$ has length $< s$, and $\Psi_{e,s} \subseteq \Psi_{e,s+1}$, and, for all $e$, $\Psi_e = \bigcup_s \Psi_{e,s}$. In any construction involving $\Psi_e$, we assume that the elements of $\Psi_{e,s} - \Psi_{e,s-1}$ are enumerated into $\Psi_e$ at the beginning of stage $s$, before any action is taken. (Let $\Psi_{e,-1}$ be $\emptyset$.) We make similar conventions for $(\Phi_{e,s})_{e,s \in \omega}$ and for the other sequences of functionals which we define later.

When we refer, during a construction, to sets and functionals which are being enumerated, we are actually referring to the finite sets and functionals consisting of those elements and axioms so far enumerated. For example, if at some point in a construction we say that $\Psi_e(A; x) = 0$, we mean that the functional consisting of those axioms so far enumerated into $\Psi_e$ when applied to the finite set consisting of those numbers so far enumerated into $A$ converges on $x$ to 0. If we put $[s]$ after an expression involving sets and functionals being enumerated, then we are actually referring to as much of those sets and functionals as has been enumerated at the point in the construction just before stage $s$. Similarly, $[s, t]$ after an expression refers to the point in stage $s$ just before substage $t$ of stage $s$ begins. After we have completed the description of a construction, when we refer to sets or functionals which were enumerated, we usually are referring to the final values. When there is a possibility for confusion, we add $[\omega]$ after an expression to emphasize that we are referring to the final values.

Suppose that $\Xi$ is a partial recursive functional of $n$ set variables and $A_1, \ldots, A_n$ are being constructed. If, at some point during the construction, $\Xi(A_1, \ldots, A_n; x) \downarrow$ and $A_1 \cup \cdots \cup A_n \uparrow u$ does not later change, where $u = \xi(A_1, \ldots, A_n; x)$, then the computation is “correct,” i.e., $\Xi(A_1, \ldots, A_n; x) \downarrow[\omega]$ by the same computation.
We use $'$ for the usual jump operation on sets and degrees. A set $A$ is low if $A' \equiv_T \varnothing'$, and a degree $a$ is low if $a' = \varnothing'$.

We let $(,) : \omega^2 \to \omega$ be some fixed recursive bijection and write $(x, y)$ for $(,) (x, y)$. If $A$ and $B$ are sets, we define $A \oplus B$ to be $\{2x : x \in A\} \cup \{2x + 1 : x \in B\}$, so $\deg(A) \cup \deg(B) = \deg(A \oplus B)$.

If $\sigma$ and $\tau$ are strings, then we write $\sigma * \tau$ for $\sigma$ concatenated with $\tau$. If $i = 0$ or $1$, we let $i$ also denote the string of length 1 whose value at 0 is $i$. We linearly order the set of strings by saying that $\sigma \leq \tau$ if either $\sigma \subseteq \tau$ or else $\sigma(x) < \tau(x)$ where $x$ is the least number such that $\sigma(x) \neq \tau(x)$.

We let $\mathcal{B}_x$ be the finite set with canonical index $x$. If $m$ is defined to be the largest number satisfying some property and there are no such numbers, then we take $m$ to be 0.

We denote the end of the proof of a theorem or corollary with the symbol $\blacksquare$. The symbol $\square$ denotes the end of a construction or of the proof of a lemma to a theorem.

2. Nonzero branching degrees below nonzero r.e. degrees. We now give the Lachlan nonzero branching degree construction. In fact, we combine the construction with permitting to show that there is a nonzero branching degree below any given nonzero r.e. degree. Our presentation of the basic construction is similar to that of Soare [12]. We refer the reader to that paper for a clear discussion of the motivation for the method of proof. Although the addition of permitting to the basic nonzero branching degree construction of Lachlan is not difficult, the observation that it can be done appears to be new.

**Theorem 2.1.** If $d$ is a nonzero r.e. degree, then there is a nonzero branching degree $c$ with $c \leq d$.

**Proof.** Let $D$ be an r.e. set in $d$ and let $\{d_s\}_{s \in \omega}$ be an effective enumeration of $D$. Let $\{(\Theta^0_e, \Theta^1_e)\}_{e \in \omega}$ be an effective enumeration of all pairs of partial recursive functionals of two set variables. We construct r.e. sets $A_0, A_1, C$ with $C \leq_T D$ by permitting, $A_i \equiv_T C$, $i = 0$ or $1$, and $\deg(C)$ the inf of $\deg(A_0 \oplus C)$ and $\deg(A_1 \oplus C)$. Then if $c = \deg(C)$, $c$ is as desired. We wish to meet, for all $e \in \omega$ and $i = 0$ or $1$, the requirements

\begin{align*}
(2.1) & \quad P^i_e : \Psi^i_e(C) \neq A_i, \\
(2.2) & \quad P^C_e : \overline{C} \neq \overline{W}_e, \\
(2.3) & \quad N^e : \Theta^0_e(A_0, C) = \Theta^1_e(A_1, C) = f, \text{ total } \rightarrow f \leq_T C.
\end{align*}

At any point in the construction we let

$$l(e) = \max\{x : (\forall y < x)(\Theta^0_e(A_0, C; y) = \Theta^1_e(A_1, C; y))\}.$$ 

Just before stage $s$, we define, by induction on $e$, a restraint function $r(e)[s]$ and hence $R(e)[s] = \max\{r(e')[s] : e' < e\}$. Suppose that we have $r(e')[s]$ for all $e' < e$, so we have $R(e)[s]$. We call $s$ $e$-maximal if

$$\left(\forall t < s\right)[R(e)[t] = R(e)[s] \rightarrow l(e)[t] < l(e)[s]]$$
and we let \( r(e)[s] \) be the maximum of

(i) those \( t < s \) such that \( R(e)[t] < R(e)[s] \), and

(ii) if \( s \) is not \( e \)-maximal, those \( t < s \) such that \( R(e)[t] = R(e)[s] \) and \( t \) is \( e \)-maximal.

We will have for each \( e \), \( \liminf R(e)[s] < \infty \), but in general \( \limsup R(e)[s] = \infty \). We will still be able to use permitting since numbers put into \( C \) are not subject to the \( R(e) \) restraints.

Let \( \{P_n\}_{n \in \omega} \) be some effective listing of the \( P_e^i \)'s and \( P_e^C \)'s. During the construction, the \( P_n \)'s are assigned followers which may later be canceled. During stage \( s \) we say that \( P_e^i = P_n \text{ requires attention} \) if no follower of \( P_e^i \) is in \( A_i \) and either

\[
(2.4) \quad \text{for some follower } x \text{ of } P_e^i, \quad x \geq R(n)[s] \text{ and } \Psi_e(C; x) = 0,
\]

or

\[
(2.5) \quad \text{for every follower } x \text{ of } P_e^i, \quad \Psi_e(C; x) = 0,
\]

and we say that \( P_e^C \text{ requires attention} \) if \( C \cap W_e = \emptyset \) and either

\[
(2.6) \quad \text{for some follower } x \text{ of } P_e^C, \quad x \in W_e \text{ and } d_x < x,
\]

or

\[
(2.7) \quad \text{for every follower } x \text{ of } P_e^C, \quad x \in W_e.
\]

We now give the construction.

Stage \( s \). Find the least \( n \) such that \( P_n \text{ requires attention} \). (This \( n \) exists since if \( P_e^i \) has no followers then \( P_e^i \text{ requires attention} \).) Cancel all followers of all \( P_n' \) with \( n' > n \). If \( P_n \) is \( P_e^i \) and there is an \( x \) satisfying (2.4), take the least such \( x \) and put it into \( A_i \); otherwise, appoint \( s \) to be a follower of \( P_n \). If \( P_n \) is \( P_e^C \) and (2.6) holds for some \( x \), put the least such \( x \) into \( C \); otherwise, appoint \( s \) to be a follower of \( P_n \). We say that \( P_n \text{ receives attention} \) at stage \( s \). 

Note that by cancellation if, at some point in the construction, \( x \) is a follower of \( P_n \) and \( y \) is a follower of \( P_n' \) with \( x < y \), then \( n < n' \).

**Lemma 1.** \( C \preceq_T D \).

**Proof.** By permitting, i.e., if \( D \uparrow x[\sigma] = D \uparrow x \), then \( C \uparrow x[\sigma] = C \uparrow x \).

**Lemma 2.** For all \( n \), \( \liminf R(n)[s] < \infty \).

**Proof.** For all \( s \), \( R(0)[s] = 0 \), so \( \liminf R(0)[s] = 0 \). Suppose that \( \liminf R(n)[s] = w < \infty \). Let \( v \) be the greatest \( s \) such that \( R(n)[s] < w \). Let \( S = \{s: R(n)[s] = w\} \). Then \( S \) is infinite. If there are infinitely many \( s \in S \) such that \( s \) is \( n \)-maximal, then for all such \( s \) which are \( > v \),

\[
R(n + 1)[s] = \max\{R(n)[s], r(n)[s]\} = \max\{w, v\}.
\]

If there are only finitely many \( s \in S \) with \( s \)-maximal, let \( s_0 \) be the greatest such \( s \). Then for any \( s \in S \) with \( s > v, s_0 \), \( R(n + 1)[s] = \max\{w, v, s_0\} \). Hence the result holds for \( n + 1 \).

**Lemma 3.** For each \( n \), \( P_n \) is met and receives attention only finitely often.
PROOF. Suppose that the conclusion of the lemma holds for all $n' < n$. Let $t_0$ be the least stage $t$ such that for no $s \geq t$ does a $P_{n'}$ with $n' < n$ receive attention. Then $P_n$ has no followers just before stage $t_0$; a follower appointed to $P_n$ at a stage $\geq t_0$ is never canceled; and if $P_n$ requires attention at a stage $\geq t_0$, then it receives attention at that stage.

Suppose that $P_n$ is $P^{i}_{n'}$. If $P_n$ receives attention at a stage $s \geq t_0$ at which (2.4) holds, then the follower of $P^{i}_{n'}$ put into $A_i$ at stage $s$ is never canceled, so $P^{i}_{n'}$ never later requires attention, so $P^{i}_{n'}$ receives attention only finitely often; also, a computation $\Psi_i(C; x) = 0$ exists at stage $s$ and is correct because any followers appointed at stages $\geq s$ will be too large to destroy the computation, all followers of $P_{n'}$ with $n' > n$ are canceled at stage $s$, $P_n$ does not put numbers into $C$, and no $P_{n'}$ with $n' < n$ receives attention at a stage $\geq s$. Thus in this case $P_n$ is met since $A_i(x)[\omega] = 1 = 0 = \Psi_i(C; x)[\omega]$. Suppose that $P^{i}_{n'}$ receives attention infinitely often. Then if $P^{i}_{n'}$ receives attention at a stage $s \geq t_0$, (2.4) fails, so $P^{i}_{n'}$ is appointed infinitely many followers. In particular, at some stage $x_0 \geq t_0$ with $x_0 = \liminf R(n)[s]$, $P^{i}_{n'}$ receives attention, so $x_0$ is assigned as a follower of $P^{i}_{n'}$ and $x_0$ is never canceled. Let $t_1 > x_0$ be a stage at which $P^{i}_{n'}$ receives attention. Then (2.5) holds at $t_1$, so $\Psi_i(C; x_0)[t_1] = 0$ and since $P_n = P^{i}_{n'}$ receives attention at stage $t_1$, this computation is correct, by the argument of the preceding paragraph. Now take $t_2 > t_1$ such that $R(n)[t_2] \leq x_0$. Then at stage $t_2 > t_0$, no follower of $P^{i}_{n'}$ is in $A_i$ (else that follower will never be canceled and $P^{i}_{n'}$ receives attention only finitely often) and (2.4) holds through $x_0$, so $P^{i}_{n'}$ requires attention. But then $P^{i}_{n'}$ receives attention at stage $t_2$ and (2.4) holds, a contradiction. Thus $P^{i}_{n'}$ receives attention finitely often.

Suppose that $P^{i}_{n'}$ fails. Then at no stage $s \geq t_0$ at which $P^{i}_{n'}$ receives attention does (2.4) hold, so for no $s \geq t_0$ is there a follower of $P^{i}_{n'}$ which is in $A_i$. Since $P^{i}_{n'}$ receives attention only finitely often, only finitely many followers of $P^{i}_{n'}$ are appointed at stages $\geq t_0$ and none of these followers is put into $A_i$, so for each such follower $x$, $0 = A_i(x)[\omega] = \Psi_i(C; x)[\omega]$. Take $s \geq t_0$ such that $P^{i}_{n'}$ does not receive attention at stage $s$ and such that for all followers $x$ of $P^{i}_{n'}$ appointed at or after stage $t_0$, $\Psi_i(C; x)[s] = 0$. Then $P^{i}_{n'}$ requires attention at stage $s$, so receives attention, a contradiction. Thus $P^{i}_{n'}$ is met.

Now suppose that $P_n$ is $P^C_n$. If $P^C_n$ ever receives attention at a stage $s$ such that (2.6) holds at stage $s$, then $C \cap W_e = \emptyset$, so $P^C_n$ is met and $P^C_n$ never requires attention after stage $s$, so receives attention only finitely often.

Suppose that $P^C_n$ receives attention infinitely often. Then each time $P^C_n$ receives attention (2.6) fails, so infinitely many followers are appointed to $P^C_n$. For each follower $x$ appointed to $P^C_n$ after stage $t_0$, $x \in W_e$, else $P^C_n$ does not receive attention after $x$ is appointed to follow $P^C_n$ (since $x$ is never canceled). Thus, given $y$, we can effectively find a stage $s \geq t_0$ such that for some follower $x > y$ of $P^C_n$ appointed after stage $t_0$ and before stage $s$, $x \in W_e[s]$. Now if, for $s' \geq s$, $d_{s'} < x$, then at stage $s'$, $C \cap W_e[s'] = \emptyset$ (else $P^C_n$ receives attention only finitely often) and (2.6) holds for $x$, so $P^C_n$ requires attention at stage $s' \geq t_0$, so receives attention and (2.6) holds, a contradiction. Thus $D \vdash \exists x[s] = D \vdash x$. But this procedure gives $D$ recursive, a contradiction. Hence $P^C_n$ receives attention only finitely often.
Now suppose that $P^C_e$ fails. Then whenever $P^C_e$ receives attention, (2.6) fails. Thus for every follower $x$ appointed to $P^C_e$, $x \in \overline{C} = W_e$. Take $s \gg t_0$ so large that $P^C_e$ does not receive attention at stage $s$ and for every follower $x$ ever appointed to $P^C_e$ (there are only finitely many such $x$), $x \in W_e[s]$. Then $C \cap W_e[s] = \emptyset$ (since $\overline{C} = W_e$) so $P^C_e$ requires attention at stage $s$, so $P^C_e$ receives attention at stage $s$, a contradiction. Thus $P^C_e$ is met. \[\square\]

**Lemma 4.** For each $e$, $N_e$ is met.

**Proof.** Suppose that $\Theta^0_e(A_0, C) = \Theta^1_e(A_1, C) = f$, $f$ total. We show how to compute $f(p)$ recursively in $C$. Let $w = \liminf_s R(e)[s]$. Take $t_0$ such that

\begin{equation}
  s \geq t_0 \Rightarrow R(e)[s] \geq w,
\end{equation}

and

\begin{equation}
  s \geq t_0, n \leq e \rightarrow P_n \text{ does not receive attention at stage } s.
\end{equation}

Let $S = \{s: R(e)[s] = w\}$, so $S$ is infinite. We have $\lim_s l(e)[s] = \infty$, so there are infinitely many $e$-maximal stages in $S$. (For each $n$, let $s_n$ be the least $s \in S$ such that $l(t)[s] \geq n$. Then $s_n$ is $e$-maximal and as $n$ runs over all integers, $s_n$ takes on infinitely many values.) Given $p$, we compute $f(p)$ recursively in $C$ as follows. Find a stage $s \gg t_0$ with $s \in S$, $s$ is $e$-maximal, $l(e)[s] > p$, and, for some $i = 0$ or $1$, $\Theta^i_e(A_i, C; p)[s + 1]$ converges by a $C$-correct computation, i.e., $C$ is correct through the use $\theta^i_e(A_i, C; p)[s + 1]$. We claim that if $q = \Theta^i_e(A_i, C; p)[s + 1]$, then $q = f(p)$. In fact we show that for all $t > s$, there is an $m < t$ and an $i = 0$ or $1$ such that $m \in S$, $m$ is $e$-maximal, $\Theta^i_e(A_i, C; p)[t] = q$ by a $C$-correct computation and $\theta^i_e(A_i, C; p)[t] \leq m$. For $t = s + 1$ we have the claim. Suppose that the claim holds for $t$. If the computation $\Theta^i_e(A_i, C; p)[t] = q$ is not injured at stage $t$, then the result holds for $t + 1$. Otherwise, since the computation is $C$-correct, a number $< \theta^i_e(A_i, C; p)[t] \leq m$ enters $A_i$ at stage $t$ and destroys the $C$-correct computation. Since $t > s \gg t_0$, $R(e)[t] \gg w$. If $R(e)[t] > w$ or if $R(e)[t] = w$ and $t$ is not $e$-maximal, then $r(e)[t] \gg m$, and, since $t \gg t_0$, no $P_n$ with $n \leq e$ receives attention at stage $t$, so no number $< m$ could enter $A_i$ at stage $t$. Thus $R(e)[t] = w$ (i.e., $t \in S$) and $t$ is $e$-maximal. Hence $p < l(e)[s] < l(e)[t]$, so a computation $\Theta^i_e(A_i, C; p)[t]$ exists and equals $\Theta^1_e(A_1, C; p)[t] = q$. This computation is not injured at stage $t$, so exists at the end of stage $t$ and we claim that it is $C$-correct. For the number $x$ which enters $A_i$ at stage $t$ is a follower of some $P_n$. Any followers of $P_n$ with $n' > n$ which exist at the beginning of stage $t$ are canceled at stage $t$. Followers of $P_n$ are not put into $C$. Any follower of a $P_{n'}$ with $n' < n$ which exists at the beginning of stage $t$ is $< x$; but then such a follower cannot be later put into $C$ since by induction hypothesis $C$ is correct through $x$ prior to stage $t$. Any followers appointed after stage $t$ will be too large to injure the computation. Thus the $\Theta^i_e(A_{-i}, C; p)[t + 1]$ computation is $C$-correct, so the result holds for $t + 1$ with $1 - i$ in place of $i$ and $t$ the new $e$-maximal stage in $S$. This establishes the lemma. \[\square\]

The theorem follows from the lemmas. Let $e = \text{deg}(C)$. Then $e \ll d$ by Lemma 1, $0 < e$ by Lemma 3, $e$ is the inf of $\text{deg}(A_0 \oplus C)$, $\text{deg}(A_1 \oplus C)$ by Lemma 4, and these latter two degrees are $> e$ by Lemma 3. \[\blacksquare\]
3. A new branching degree construction. The delicate argument of Lemma 4 in the previous theorem does not combine well with the injuries which result from trying to code in a given incomplete r.e. degree into the branching degree \( c \), even if the degree being coded in is low. We present a new branching degree construction which we will later use to show that there is a branching degree above any given low r.e. degree. In the Lachlan branching degree construction, the minimal pair type requirements \( N_e \) are met solely by negative restraint. (It is for this reason that they have traditionally been called \( N_e \).) In our new construction, the \( N_e \)'s are met solely by positive action.

In [2], Lachlan, in what has become known as the nondiamond theorem, showed that if two incomparable r.e. degrees have join \( 0' \), then they do not have inf \( 0 \). Lachlan asked if two incomparable r.e. degrees which join to \( 0' \) can have any degree as their inf. This question, known as the generalized nondiamond question, was answered affirmatively by Shoenfield and Soare [9] and, independently, Lachlan proved a result (the Lachlan Splitting Theorem [4]) which as a corollary also gives an affirmative answer to his earlier question. We introduce our new branching degree construction by using it to give a new proof of this answer to Lachlan's question.

We wish to construct r.e. sets \( A_0, A_1 \) and \( C \) to meet requirements \( P_e \) and \( N_e \), for all \( e \) and for \( i = 0 \) or \( 1 \), given by (2.1) and (2.3). Let \( \{R_e\}_{e \in \omega} \) be some effective ordering of the \( P_e \)'s. We meet the \( N_e \)'s as follows. When \( \Theta_0^e(x) = \Theta_1^e(x) \) (we drop set arguments during this discussion), we put down a marker \( \lambda_x^e \) on some large number not yet in \( C \) and set \( A_x = 0^e(x) \). Then if later in the construction neither \( \Theta_0^e(x) \) nor \( \Theta_1^e(x) \) gives the answer \( \Lambda_x^e \), we need to change our mind on \( A_x \), so we put \( \lambda_x^e \) into \( C \) which frees us to later define a new value for \( \lambda_x^e \) and set \( \Lambda_x^e \) equal to the new common value \( \Theta_0^e(x) = \Theta_1^e(x) \). If the \( \Theta_0^e(x), \Theta_1^e(x) \) values change again, we repeat the process. The \( N_e \)'s will be met as long as they face a finite amount of restraint.

To meet \( P_e \) we try a Friedberg-Muchnik type argument, i.e., \( R_e = P_e \) has a diagonalization witness \( x_n \) which is kept out of \( A_i \) until \( \Psi_e(x_n) = 0 \). When this happens, we want to put \( x_n \) into \( A_i \) and hold \( C \) on the use of the computation. We can let \( R_e \), cancel \( N_e \), if \( e' \geq n \), i.e., remove \( \lambda_x^e \) markers which threaten to later go into \( C \) to destroy the computation, but \( R_e \) still has to deal with the \( \lambda_x^e \) markers with \( e' < n \) which might harm the computation. The essential idea is that, although \( R_e \) cannot keep such a \( \lambda_x^e \) from entering \( C \) if it later wants to, \( R_e \) can do something to keep \( \lambda_x^e \) from ever wanting to go into \( C \). The fact that \( \lambda_x^e \) has a value means that at least one of \( \Theta_0^e(x), \Theta_1^e(x) \) has a value. If \( R_e \) can restrain \( A_0 \cup C \) or \( A_1 \cup C \) (whichever is appropriate) on the use, then the computation \( \Theta_0^e(x) \) or \( \Theta_1^e(x) \) will not be destroyed and \( \lambda_x^e \) will never want to enter \( C \). The problem is that we are only guaranteed convergence of one of \( \Theta_0^e(x), \Theta_1^e(x) \) and this convergence may be destroyed when \( R_e \) puts \( x_n \) into \( A_i \) to diagonalize, so \( R_e \) cannot keep \( \lambda_x^e \) from wanting to go into \( C \). The solution is for \( R_e \) to make a guess about each \( N_e \) with \( e' < n \). The guess is whether or not the apparent length of agreement between \( \Theta_0^e \) and \( \Theta_1^e \) will be unbounded. If not, then, if we require that new values of \( \lambda_x^e \) be put down only at \( "e'\)-maximal" stages, i.e., at stages at which there is a longer length of agreement between \( \Theta_0^e \) and \( \Theta_1^e \) than ever before, then \( R_e \) can simply ignore \( \lambda_x^e \)
markers since after some stage such numbers stop going into $C$. If, on the other hand, there will be infinitely many $e'$-maximal stages, then $R_n$ can wait for an $e'$-maximal stage before acting. At such a stage, both $\Theta^0_n(x)$ and $\Theta^1_n(x)$ converge for all $x$ for which $\lambda^x_n$ is defined. Thus $R_n$ can put on restraint to protect the one of these computations which its attack will not destroy and hence keep $N_e$ from wanting to put $\lambda^x_n$ into $C$.

Thus $R_n$ has $2^n$ strategies, one for each string of length $n$. If $\delta_n$ is the highest priority strategy of length $n$ which looks correct infinitely often, then $\{\delta_n\}_{n \in \omega}$ is a path through $2^{<\omega}$, the $\delta_n$ strategy for $R_n$ wins $R_n$, and $\delta_n$ acts only finitely often. The overall requirement $R_n$, through its $2^n$ strategies, may act infinitely often, but the strategies for $R_n$ which act infinitely often will be of lower priority than the correct path through the tree of strategies, so will not interfere with strategy $\delta_n$, even when $n'$ is $> n$. This tree of strategies technique was begun by Lachlan in his “monster” paper [3]. Our tree of strategies is similar to that in [4].

At stage $s$ we define inductively $\beta_s$ in $2^s$ such that for each $n \leq s$, $\beta_s \upharpoonright n$ is the strategy for $R_n$ which looks correct at stage $s$. For $e < s$, we set $\beta_s(e) = 0$ iff $s$ is an $e$-maximal stage, i.e., iff for all $t < s$, if $\beta^e_t \neq \beta^e_s$, then $l(e)[t] < l(e)[s]$ where $l(e)$ is as defined in the proof of Theorem 2.1. We want that if $\beta_s(e) = 0$ and $\lambda^x_s$ is defined at stage $s$, then $x < l(e)[s]$, so both $\Theta^0_s(x)$ and $\Theta^1_s(x)$ are defined. But for some $t < s$ with $\beta^e_t \neq \beta^e_s$, we could have had $l(e)[t]$ very large so that $\lambda^x_s$ could become defined for some $x > l(e)[s]$. To get around this problem, we let $N_e$ build $2^e$ reductions $\Lambda^e$, one for each string $\alpha$ of length $e + 1$ which ends in a 0; $\Lambda^e$ is played at stage $s$ only if $\alpha \subseteq \beta_s$. Then if $s$ is $e$-maximal and $\lambda^x_{s+e+1}$ is defined, we must have $x < l(e)[s]$ as we wanted. At stage $s$ we may cancel any values of $\lambda^x_s$ with $\beta_s \upharpoonright e + 1 < \alpha$, so these reductions will not bother us.

We now turn to the detailed construction.

**Theorem 3.1.** There are r.e. degrees $c, a_0$ and $a_1$ such that $a_0$ and $a_1$ are incomparable, $c$ is the inf of $a_0$ and $a_1$, and $\Theta'$ is the join of $a_0$ and $a_1$.

**Proof.** We construct r.e. sets $C$, $A_0$ and $A_1$ and set $c = \deg(C)$, $a_i = \deg(A_i \oplus C)$, $i = 0$ or 1. We wish to meet for all $e \in \omega$ and $i = 0$ or 1 requirements $N_e$ and $P^e_i$ given by (2.3) and (2.1). Let $\{P^e_n\}_{n \in \omega}$ be some effective ordering of the $P^e_i$'s. For each string $\alpha$ of length $n$, there is a strategy for $R_n$. We will identify $\alpha$ with this strategy, so we will say “$\alpha$ requires (receives) attention” instead of “strategy $\alpha$ of $R_n$ requires (receives) attention.” If $l(\alpha) = n$ and $R_n$ is $P^e_i$, we write $A_\alpha$ for $A_i$, $\Psi_\alpha$ for $\Psi_i$, and $\psi_\alpha$ for $\psi_e$. Strategy $\alpha$ for $R_n$ tries to win $R_n$ by diagonalization on a number $x_\alpha$.

The value of $x_\alpha$ may be canceled and redefined throughout the construction. For each $\alpha$ of length $e + 1$ with $\alpha(e) = 0$, there are markers $\lambda^x_\alpha$ and values $\Lambda^x_\alpha$, for each $x$, which may be assigned and canceled throughout the construction.

At any point in the construction we say that $\alpha$ requires attention if either

\[
\text{(3.1)} \quad x_\alpha \text{ is undefined,}
\]

or

\[
\text{(3.2)} \quad x_\alpha \text{ is defined, } x_\alpha \not\in A_\alpha, \text{ and } \Psi_\alpha(C; x_\alpha) = 0.
\]
If, at some point in the construction, we have $x_\alpha$ defined with $x_\alpha \in A_\alpha$ and
$
\Psi_\alpha(C; x_\alpha)$ does not converge to 0, then $x_\alpha$ is canceled.

At any point in the construction we let, as in the proof of Theorem 2.1,
$$l(e) = \max\{x: (\forall y < x)[\Theta_e^0(A_0, C; y) = \Theta_e^1(A_1, C; y)]\}$$
and (say we are in stage $s$) we define $\beta \in 2^\omega$ by induction on $e$ by
$$\beta(e) = 0 \leftrightarrow (\forall t < s) \land \beta_t \uparrow e = \beta \uparrow e \rightarrow l(e)[t, 2] < l(e),$$
where $\beta_t$ is an element of $2^t$ which is defined at stage $t$.

Let $K$ be a complete r.e. set and let $\{k_s\}_{s \in \omega}$ be a one-one recursive enumeration of $K$. We now give the construction.

**Stage $s$.** **Substage 1.** For each $\alpha$ and $x$ such that $\lambda_\alpha^x$ is defined, if neither
$\Theta_{\lambda_\alpha^x-1}(A_0, C; x)$ nor $\Theta_{\lambda_\alpha^x-1}(A_1, C; x)$ converges to $\Lambda_\alpha^x$, then enumerate $\Lambda_\alpha^x$ into $C$
and cancel $X_\alpha x$ and $\Lambda_\alpha^x$. Repeat this process until for every $\Lambda_\alpha^x$ which is defined, at
least one of $\Theta_{\lambda_\alpha^x-1}(A_0, C; x)$, $\Theta_{\lambda_\alpha^x-1}(A_1, C; x)$ converges to $\Lambda_\alpha^x$.

Let $\beta_s$ be the current value of $\beta$, restricted to $s$.

**Substage 2.** See if for any $n < s$, $\beta_t \uparrow n$ requires attention. If not, then substage 2 is
over. If so, take $n$ minimal and set $\alpha = \beta_t \uparrow n$. Then $\alpha$ receives attention at stage $s$. If
$x_\alpha$ is undefined, then let $x_\alpha$ be $2s + 1$ and substage 2 is over. Otherwise, enumerate $x_\alpha$
into $A_\alpha$, enumerate a restraint of priority $\alpha$ equal to $s$, and cancel all $\lambda_\alpha^x$, $\Lambda_\alpha^x$, and
$x_\alpha$, with $\alpha < a'$.

**Substage 3.** For each $e < s$ such that $\beta_e(e) = 0$, find the least $p < l(e)[s, 2]$, if any, such that
$\Theta_p^0(A_0, C; p) = \Theta^1_p(A_1, C; p) = q$, say, and $\lambda^p_{\beta_e(e) + 1}$ is undefined and then
define $\lambda^p_{\beta_e(e) + 1}$ to be a number larger than any used in the construction so far and
define $\Lambda^p_{\beta_e(e) + 1} = q$.

**Substage 4.** Find the least $a$, if any, such that $2 \cdot k_s$ is a restraint of priority $\alpha$. If
this $a$ exists, put $2 \cdot k_s$ into $A_\alpha$. Otherwise, put $2 \cdot k_s$ into $A_0$.

**Lemma 1.** $K \subseteq T \cdot A_0 \oplus A_1$.

**Proof.** We have $x \in K \leftrightarrow 2x \in A_0 \cup A_1$. 

For each $s \geq n$, $\beta_s \uparrow n$ is a string of length $n$. Since there are only $2^n$
strings of length $n$, we can define $\delta_n$ to be the least string of length $n$ which is equal to $\beta_s \uparrow n$
for infinitely many $s \geq n$. Furthermore, for all $n$,

\begin{equation}
\delta_n \subseteq \delta_{n+1}.
\end{equation}

To see (3.3), let $a = \delta_{n+1} \uparrow n$. If $s \geq n + 1$ and $\beta_s \uparrow n + 1 = \delta_{n+1} \uparrow n = a$. Since there are infinitely many $s \geq n + 1$ with $\beta_s \uparrow n + 1 = \delta_{n+1} \uparrow n = a$. Conversely, if $s \geq n + 1$ and $\beta_s \uparrow n = \delta_n$, then for some $i = 0$ or 1, $\beta_s \uparrow n + 1 = \delta_n \uparrow i = i$. Hence there is a fixed $i_0 = 0$ or 1 such that for infinitely many $s \geq n + 1$,
$\beta_s \uparrow n + 1 = \delta_n \uparrow i_0$. Thus $a \uparrow i \cdot \delta_{n+1}(n) = \delta_{n+1} \uparrow i = i_0$. It follows that $a \uparrow i \cdot \delta_n \uparrow i_0$, as desired.

**Lemma 2.** For each $n$, $R_n$ is met and $\delta_n$ receives attention only finitely often.

**Proof.** Assume that the result holds for all $n' < n$. Suppose that at stage $s$ some $\alpha$
with $\alpha < \delta_n$, $\alpha \subseteq \delta_n$ receives attention. Then, by (3.3), $\alpha = \delta_{n'}$ with $n' = 1 \alpha < n$, so
by induction hypothesis there are only finitely many such s. Also, suppose that s \geq n
and at stage s some a with \alpha < \delta_n, \alpha \not\subseteq \delta_n receives attention. Then, by construction,
\alpha \subseteq \beta', so \beta' \uparrow n < \delta_n; but by definition of \delta_n there are only finitely many such s.
Thus, only finitely often does a strategy of higher priority than \delta_n receive attention,
so there is only finitely much restraint of priority < \delta_n put on during the construction.
Let q be the largest such restraint.

Now also, if s \geq n and at stage s a value is assigned to \lambda^a_m for some m and \alpha with
\alpha < \delta_n, \alpha \not\subseteq \delta_n, then \alpha \subseteq \beta', so \beta' \uparrow n < \delta_n. Hence only finitely many numbers are
ever assigned to be \lambda^a_m for some m and \alpha with \alpha < \delta_n, \alpha \not\subseteq \delta_n.

Thus we may take s_0 \geq n such that

\begin{equation}
\alpha < \delta_n, s \geq s_0 \rightarrow \alpha \text{ does not receive attention at stage s},
\end{equation}

\begin{equation}
\alpha < \delta_n, \alpha \not\subseteq \delta_n \rightarrow \text{if x is ever assigned to be } \lambda^a_m \text{ for some m,}
\quad \text{and } x \in C, \text{ then } x \in C[s_0],
\end{equation}

and

\begin{equation}
K \uparrow q[s_0] = K \uparrow q.
\end{equation}

Let A_{\delta_n} = A_. Then it follows from (3.6) that at no stage s \geq s_0 does 2 \cdot k_s enter A_{1-i}
if 2 \cdot k_s is < a restraint of priority \delta_n which exists at substage 4 of stage s.

Suppose that at some stage s \geq s_0, \delta_n receives attention and x_{\delta_n} is put into
A_{\delta_n} = A_. Then \Psi_{(C; x_{\delta_n})}[s, 2] = 0. We claim that this computation is correct. In
fact we show that A_{1-i} \cup C \uparrow s[s, 2] = A_{1-i} \cup C \uparrow s which suffices to show the claim.
Suppose that \psi is the first number < s which enters A_{1-i} \cup C after substage 1 of
stage s, say \psi enters A_{1-i} \cup C at stage \psi \geq s \geq s_0. Then \psi is not 2 \cdot k_s, since at
substage 2 of stage s a restraint of priority \delta_n equal to s is enumerated. Suppose that
\psi = x_\alpha for some \alpha. When x_{\delta_n} is put into A_, at stage s, we cancel x_{\gamma} for \gamma > \delta_n
and any later values of x_{\gamma} will be > s, so we cannot have \alpha > \delta_n. We rule out \alpha = \delta_n
since no values of x_{\delta_n} are put into A_{1-i} and \alpha < \delta_n is ruled out by (3.4) since x_\alpha put
into A_{1-i} at stage s' implies \alpha receives attention at stage s'. Thus \psi = x_\alpha is
impossible. The only remaining possibility is w = \lambda^a_m for some m and \alpha. When x_{\delta_n} is
put into A_ at stage s, we cancel \lambda^a_m for all \alpha > \delta_n and any later values of \lambda^a_m will be
> s, so \alpha > \delta_n is impossible. We cannot have \alpha < \delta_n, \alpha \not\subseteq \delta_n by (3.5), so we must
have \alpha \subseteq \delta_n. Since w < s, \lambda^a_m must have been assigned to w before stage s,
say at stage v < s where we must have \alpha \subseteq \beta_\psi(s \text{ lha} \psi < v) and m < l(l(ha - 1)[v, 2].
Now \alpha(l(ha - 1) = 0 and \alpha \subseteq \delta_n \subseteq \beta_\psi, so \beta_\psi(l(ha - 1) = \alpha(l(ha - 1) = 0, i.e.,
\beta(l(ha - 1)[s, 2] = 0. We have l(ha - 1) \leq v < s and \beta_\psi(l(ha - 1) = \beta_\psi(l(ha - 1) = \beta_\psi l(ha - 1) = \psi = 0, so by definition of \beta(l(ha - 1) = 0 we must have
m < l(l(ha - 1)[v, 2] < l(l(ha - 1)[s, 2]. Thus, just prior to substage 2 of stage s, both
\Theta^1_{l(ha - 1)}(A_0, C; m) and \Theta^1_{l(ha - 1)}(A_1, C; m) converge to some number, say p. We must
have p = \lambda^a_m[s, 2], else at substage 1 of stage s, \lambda^a_m would be canceled. But when
w = \lambda^a_m is put into C at stage \psi, \Theta^1_{l(ha - 1)}(A_{1-i}, C; m) does not converge to p, so at
some point after substage 1 of stage s and before w is put into C a number < s has
entered A_{1-i} \cup C to destroy the computation \Theta^1_{l(ha - 1)}(A_{1-i}, C; m)[s, 2]. This
contradicts choice of w. Thus w = \lambda^a_m is ruled out and the claim is proved. But then,
since \( s \gg s_0 \) and \( \Psi_\delta(C; x_\delta)[s, 2] = 0 \) by a correct computation, \( x_\delta \) is not canceled at a stage \( \geq s \), so \( \delta_n \) never requires attention at a stage \( > s \), so \( \delta_n \) receives attention only finitely often.

If the case of the preceding paragraph fails to hold, so that if \( \delta_n \) receives attention at a stage \( s \geq s_0 \) then \( x_\delta \) is not put into \( A_t \) at stage \( s \), then we again have that \( \delta_n \) receives attention only finitely often. For suppose that at some stage \( t \geq s_0 \), \( \delta_n \) receives attention. Then \( x_\delta \) is assigned a value at stage \( t \) and this value is not in \( A_t \), when \( x_\delta \) is assigned to it, so, by our assumption, this value will never be put into \( A_t \). But then, by (3.4), \( x_\delta \) is never canceled from the value assigned to it at stage \( t \), so no new value will ever be assigned to \( x_\delta \). Thus again \( \delta_n \) receives attention only finitely often.

Finally, to see that \( R_n \) is met, since \( \delta_n \) receives attention finitely often, \( x_\delta \) is either eventually permanently defined or eventually permanently undefined. Suppose that the latter case holds. Then for some \( s \gg s_0 \) with \( \delta_n \subseteq \beta_s \), \( x_\delta \) is permanently undefined by stage \( s \). But then \( \delta_n \) requires attention, via (3.1), throughout stage \( s \), so, by (3.4), \( \delta_n \) receives attention at stage \( s \) and \( x_\delta \) is assigned a value, a contradiction. Thus \( x_\delta \) is eventually permanently defined. If the final value \( x_\delta[\omega] \) is in \( A_t \), then we cannot have \( \Psi_\delta(C; x_\delta[\omega]) = 1 \), else \( x_\delta \) would be canceled and this value would not be the final value of \( x_\delta \), so \( R_n \) is won on \( x_\delta[\omega] \). If \( x_\delta[\omega] \) is not in \( A_t \), then we cannot have \( \Psi_\delta(C; x_\delta[\omega]) = 0 \) else at some large enough stage \( s \gg s_0 \) with \( \delta_n \subseteq \beta_s \), \( \delta_n \) would require attention through (3.2) and \( x_\delta[\omega] \) would be put into \( A_t \), a contradiction, so again \( R_n \) is won on \( x_\delta[\omega] \).

**Lemma 3.** For all \( e \), \( N_e \) is met.

**Proof.** Suppose that \( \Theta^0_e(A_0, C) = \Theta^1_e(A_1, C) = f \), \( f \) total. Then we claim that \( \delta_{e+1}(e) = 0 \). To see this, let \( S = \{s \geq e\colon \beta_s \uparrow e = \delta_e\} \). Then \( S \) is infinite and \( \lim_{s \in S} l(e)[s, 2] = \infty \). Given \( n \), let \( s_n \) be the least \( s \in S \) with \( l(e)[s, 2] > n \). Then if \( e \leq t < s_n \) and \( \beta_t \uparrow e = \beta_t \uparrow [s_n, 2] = \beta_t \uparrow e = \delta_e \), then \( t \in S \), so by definition of \( s_n \), \( l(e)[t, 2] < n \leq l(e)[s_n, 2] \), and hence, by definition of \( \beta \), \( \beta(e)[s_n, 2] = 0 \). If \( s_n > e \), then \( \beta_{s_n}(e) = \beta(e)[s_n, 2] = 0 \), so \( \beta_{s_n} \uparrow e + 1 = \delta_e \cdot 0 \). As \( n \) runs over all integers, \( s_n \) takes on infinitely many values, so by (3.3), \( \delta_{e+1} = \delta_e \cdot 0 \) and \( \delta_{e+1}(e) = 0 \).

As in the proof of Lemma 2, there is a stage \( s_0 \) such that if \( s \geq s_0 \) and \( \alpha < \delta_{e+1} \), then \( \alpha \) does not receive attention at stage \( s \). Thus if a value of \( \lambda^{e+1}_m \) is canceled at a stage \( \geq s_0 \), then \( \lambda^{e+1}_m \) is put into \( C \) (for the first time) at that stage. Thus if each \( \lambda^{e+1}_m \) comes to a final value, these final values can be found recursively in \( C \) and then the corresponding final values of \( \Lambda^{e+1}_m \) can be determined. Hence it only remains to show that for each \( m \), \( \lambda^{e+1}_m \) reaches a final value and that the corresponding final value of \( \Lambda^{e+1}_m \) is \( f(m) \). Suppose that this holds for all \( m' < m \). Then take \( s_1 \gg s_0 \) such that

\[
(3.7) \quad m' < m \rightarrow \lambda^{e+1}_{m'} \text{ has obtained its final value prior to stage } s_1, \quad \text{and}
\]

\[
(3.8) \quad l(e)[s_1] > m \text{ and all the computations for } \Theta^0_e, \Theta^1_e \text{ on numbers } \leq m \text{ existing just before stage } s_1 \text{ are correct.}
\]
If \( \lambda_{m}^{\delta s} \) is defined just prior to stage \( s \), and \( \Lambda_{m}^{\delta s}[s] = f(m) \), then \( \lambda_{m}^{\delta s+1} \) will never be canceled (by (3.8) and the fact that \( s \geq s_{0} \)), as desired. If \( \lambda_{m}^{\delta s+1}[s] \) is defined and \( \Lambda_{m}^{\delta s+1}[s] \neq f(m) \), then \( \lambda_{m}^{\delta s+1} \) is canceled at stage \( s \). If \( \lambda_{m}^{\delta s+1} \) is ever assigned a value at a stage \( s \geq s_{1} \), then at this stage, by (3.8), \( \Lambda_{m}^{\delta s} \) is set equal to \( f(m) \) and is never canceled from this value. Hence we will be done if we can show that if \( \lambda_{m}^{\delta s+1} \) is undefined at some point during a stage \( s \geq s_{1} \), then it will later be defined. Let \( s' > s, e + 1 \) be such that \( \beta_{s}(e) = 0, m < l(e)[s', 2] \) (by (3.8)) and \( m \) is the least \( m' \) such that \( x_{stf} = t_{te+1} \) is undefined (by (3.7)). Thus \( \lambda_{m}^{\delta s+1} \) is defined at stage \( s' \), completing the proof. \( \square \)

Now by Lemma 1, \( a_{0} \cup a_{1} = 0' \); by Lemma 2, \( a_{0} \) and \( a_{1} \) are \( \geq c \); and by Lemma 3, \( a_{0} \) and \( a_{1} \) inf to \( c \), as desired. \( \blacksquare \)

4. The Robinson technique. We would like to carry out the construction of Theorem 3.1 above an arbitrary low r.e. degree. In [5], Robinson introduced a technique for lifting a construction in the r.e. degrees above a given low r.e. degree. We discuss the technique and then illustrate its use by proving a special case of the Robinson Splitting Theorem.

Say \( D \) is a low r.e. set. Roughly speaking, Robinson discovered that there is an oracle procedure for answering questions of the form "is \( \mathbb{R}_{X} \subseteq D \)?" The oracle procedure may give a false positive answer, but never a false negative answer. Under certain conditions, the number of false positive answers is manageable. A typical situation is where we have a strategy for requirement \( R_{n} \) which from time to time sees an apparent computation \( \Phi_{e}(A, D; x) \), where \( A \) is a set under construction, and would like to make an attack if the computation is correct. The strategy can take steps to ensure that the computation is \( A \)-correct, but needs the oracle procedure to know whether \( \mathbb{R}_{X} \subseteq D \) where \( \mathbb{R}_{X} \) consists of those numbers \( < \) the use in the computation which have not yet appeared in \( D \). If the oracle procedure gives a positive answer, an attack is made. The positive answer may turn out to be false, or a higher priority strategy may force a number into \( A \) destroying the computation even though the oracle procedure's positive answer was correct. If we ensure that the latter case can happen only finitely often, then the former case can happen only finitely often, and \( R_{n} \) is met. The result which gives us this oracle procedure is contained in the following theorem.

**Theorem 4.1.** If \( D \) is an r.e. set, then \( D \) is low iff there is a recursive function \( f \) such that for all \( j \),

\[
W_{j} \cap \{x: \mathbb{R}_{X} \subseteq D\} = W_{f(j)} \cap \{x: \mathbb{R}_{X} \subseteq D\},
\]

and

\[
W_{j} \cap \{x: \mathbb{R}_{X} \subseteq D\} \text{ finite} \rightarrow W_{f(j)} \text{ finite}.
\]

**Proof.** This result is similar to Theorem 2.7 of [11]. It can be obtained by combining these two results from [11]: the characterization of low r.e. sets given just prior to Theorem 2.7 and Theorem 2.6. \( \blacksquare \)
The theorem is used to give the oracle procedure in the following way. If \( R_n \) wants to know whether or not \( \mathcal{D}_x \subset D \), then \( x \) is enumerated into a set \( W_{j,n} \) (the recursion theorem allows us to assume that for each \( n \) we know the r.e. index for the set of characteristic indices about which \( R_n \) asks) and we look ahead in the enumeration of \( D \) to see if a number in \( \mathcal{D}_x \) later appears in \( D \) while simultaneously looking for \( x \) in \( W_{f,j,n} \). By (4.1) one of these two searches must succeed. If the latter one succeeds first, \( R_n \) makes an attack on the assumption that the computation is correct. Equation (4.2) implies that if \( R_n \) asks about only finitely many \( \mathcal{D}_x \)'s with \( \mathcal{D}_x \subset D \), then the oracle procedure can give only finitely many different false positive answers.

We illustrate this technique by proving a result which is a weak form of our main theorem, Theorem 5.1, and is also a special case of the Robinson Splitting Theorem [5, Corollary 9], one of the original results obtained with the Robinson technique. In this proof we show explicitly how the recursion theorem is used. In later proofs we will use the recursion theorem implicitly and not give details.

**Theorem 4.2.** Let \( d \) be a low r.e. degree. Then there are incomparable r.e. degrees \( a_0 \) and \( a_1 \), both \( \geq d \), such that \( a_0 \cup a_1 = 0' \).

**Proof.** Let \( D \) be an r.e. set in \( d \). We construct r.e sets \( A_0 \) and \( A_1 \) and set \( a_i = \deg(A_i \oplus D) \). For each \( e \in \omega \) and \( i = 0 \) or 1 we have the requirement

\[
(4.3) \quad R_e: \Phi_e(A_{i-1}, D) \neq A_i.
\]

Let \( \{R_e\}_{e \in \omega} \) be an effective listing of all the \( R_e \)'s. We attempt to meet \( R_n \) by diagonalization on a number \( x_n \). The value assigned to \( x_n \) may be defined, canceled, and redefined throughout the construction.

During stage \( s \) we say that \( R_n = R'_e \) requires attention if either

\[
(4.4) \quad x_n \text{ is undefined,}
\]

or

\[
(4.5) \quad x_n \text{ is defined, } x_n \not\in A_i, \text{ and } \Phi_e(A_{i-1}, D; x_n) = 0.
\]

If at some point in the construction \( x_n \in A_i \) and \( \Phi_e(A_{i-1}, D; x_n) \) does not converge to 0, then \( x_n \) is canceled.

Since \( D \) is low, there is a recursive function \( f \) satisfying (4.1) and (4.2). We give a construction which depends on a parameter \( r \). In the \( r \)th construction, we construct a set of \( Q_r \) which consists of those numbers \( \langle n, x \rangle \) where \( R_n \) asks about \( \mathcal{D}_x \). In the \( r \)th construction, we proceed as if \( Q_r = W_r \). By the recursion theorem, for some construction, say the \( r_0 \)th, this assumption will be true, and it is the \( r_0 \)th construction which works. Let \( \{h_n\}_{n \in \omega} \) be a uniformly recursive sequence of recursive functions such that for all \( x \), \( W_{h_n(x)} = \{y: \langle n, y \rangle \in W_r\} \).

Let \( K \) be an r.e. set of degree \( 0' \) and let \( \{k_s\}_{s \in \omega} \) be a one-one recursive enumeration of \( K \). We now give the construction.

**Stage s. Substage 1.** For each \( n, n \leq s \), such that \( R_n \) requires attention, starting with the least such and continuing in increasing order until either some \( R_n \) receives attention or else no more \( n \)'s are left, proceed as follows. Let \( R_n \) be \( R'_e \). If (4.4) holds
for $n$, then appoint $2s + 1$ to be $x_n$ and $R_n$ receives attention. Otherwise, (4.5) holds. Let $\Box_x = \bar{D} \upharpoonright \Phi_e(A_{i-1}, D; x_n)$ and put $\langle n, x \rangle$ into $Q_r$. Begin looking ahead in the enumeration of $D$ for an element of $\Box_x$ to appear in $D$ and at the same time search for $x$ in $W_{f_{h,r}}$. (If neither search terminates, the construction peters out here.) If the latter search terminates first, enumerate $x_n$ into $A_i$, enumerate a restraint of priority $n$ equal to $s$ and cancel all $x_{n'}$ with $n' > n$; $R_n$ receives attention. If the former search terminates first, $R_n$ does not receive attention; go on to the next $n$, if any.

Substage 2. Find the least $n$ such that $2 \cdot k_s$ is a restraint of priority $n$. If $n$ exists and $R_n = R'_e$, put $2 \cdot k_s$ into $A_i$. Otherwise, put $2 \cdot k_s$ into $A_0$. \(\square\)

The instructions for this construction depend uniformly on $r$. Hence there is a recursive function $g$ such that $Q_r = W_{g(r)}$ for all $r$. By the recursion theorem, there is an $r_0$ with $W_{g(r_0)} = W_{r_0}$ and $Q_{r_0} = W_{r_0}$. In the $r_0$th construction, if $\langle n, x \rangle$ is put into $Q_{r_0} = W_{r_0}$ (so $x \in W_{h,(r_0)}$), then either $\Box_x \subseteq \bar{D}$ or else

\[
x \in W_{h,(r_0)} \cap \{ x : \Box_x \subseteq \bar{D} \} = W_{f_{h,(r_0)}} \cap \{ x : \Box_x \subseteq \bar{D} \},
\]

so $x \in W_{f_{h,(r_0)}}$. Thus the $r_0$th construction never peters out. From now on we refer only to the $r_0$th construction.

**Lemma 1.** $K \upharpoonright q[s_0] = K \upharpoonright q$.

**Proof.** We have $x \in K \iff 2x \in A_0 \cup A_1$. \(\square\)

**Lemma 2.** For all $n$, $R_n$ receives attention only finitely often and is met.

**Proof.** Suppose that the result holds for all $n' < n$. Then there is only finitely much restraint of priority $< n$ put on during the construction. Let $q$ be the largest such restraint. Let $s_0$ be such that

\[(4.6) \quad s \geq s_0, \quad n' < n \rightarrow R_{n'} \text{ does not receive attention at stage } s,
\]

and

\[(4.7) \quad K \upharpoonright q[s_0] = K \upharpoonright q.
\]

Let $R_n$ be $R'_e$. If $x_n$ is put into $A_i$ at a stage $s \geq s_0$, then all values of $x_{n'}$ with $n' > n$ are canceled and a restraint of priority $n$ equal to $s$ is enumerated, so by (4.6) and (4.7), $A_{1-1} \upharpoonright s[s] = A_{1-1} \upharpoonright s$.

Now suppose that at some stage $s \geq s_0$ a number $\langle n, x \rangle$ is put into $Q_{r_0} = W_{r_0}$ and $\Box_x \subseteq \bar{D}$. Then $x_n$ is put into $A_i$ at stage $s$ and the computation $\Phi_e(A_{1-i}, D; x_n) = 0$ which exists at stage $s$ is correct. Hence, by (4.6), $x_n$ is never later canceled and $R_n$ never later requires attention, so no further numbers $\langle n, x \rangle$ are put into $W_{r_0}$. Thus $W_{h,(r_0)} \cap \{ x : \Box_x \subseteq \bar{D} \}$ is finite, so, by (4.2), $W_{f_{h,(r_0)}}$ is finite.

Suppose that $x_n$ is put into $A_i$ at stages $s_1$ and $s_2$ with $s_2 > s_1 \geq s_0$. Then, for $j = 1$ or 2, at stage $s_j$, $\langle n, y_j \rangle$ is put into $W_{r_0}$, where $\Box_{y_j} \subseteq \bar{D}[s_j, 1]$ and $y_j \in W_{f_{h,(r_0)}}$. When $x_n$ is put into $A_i$ at stage $s_1$, there is a computation $\Phi_e(A_{1-i}, D; x_n)[s_1, 1] = 0$. As long as this computation remains, $x_n$ is not canceled and $R_n$ does not receive attention. Since the computation is $A_{1-1}$-correct, before or at stage $s_2$ a number in $\Box_{y_2}$ must appear in $D$ to destroy the computation. Since $\Box_{y_1} \subseteq \bar{D}[s_2, 1]$, $y_2 \neq y_1$. Since $W_{f_{h,(r_0)}}$ is finite, it follows that for some $t_0 \geq s_0$, $x_n$ is not put into $A_i$ at any
stage \( t \geq t_0 \). Now if \( R_n \) receives attention at a stage \( t \geq t_0 \), (4.4) must hold, so \( x_n \) is appointed a new value. This new value is not in \( A_i \) and will never be put in, so by (4.6) \( x_n \) will never be canceled from this value, so \( R_n \) never later receives attention. Hence \( R_n \) receives attention only finitely often.

If \( x_n \) is undefined just before some stage \( s \geq s_0, n \), then \( R_n \) requires attention, so receives it and \( x_n \) is assigned a value. Thus \( x_n \) has a final value. If the final value of \( x_n \) is in \( A_i \), then we cannot have \( \Phi_e(A_{i+1}, D; x_n[\omega]) = 1 \), else \( x_n \) would be canceled and \( x_n[\omega] \) would not be the final value, so \( R_n \) is won on \( x_n[\omega] \). If \( x_n[\omega] \notin A_i \), then we cannot have \( \Phi_e(A_{1-i}, D; x_n[\omega]) = 0 \) else at some large enough stage \( s \geq s_0 \), \( R_n \) would require attention via (4.5) and the number \( \langle n, x \rangle \) put into \( W_{s_0} \) would have \( \Diamond_x \subseteq \bar{D} \), since \( s \) is so large that the true computation holds at stage \( s \), so \( x_n[\omega] \) is put into \( A_i \), a contradiction. Thus again \( R_n \) is won on \( x_n[\omega] \).

The theorem follows from the lemmas. Let \( a_i = \deg(A_i \oplus D) \) for \( i = 0 \) or \( 1 \). Then \( d \leq a_0, a_1 \). By Lemma 1, \( 0' \leq a_0 \cup a_1 \) and by Lemma 2, \( a_0 \) and \( a_1 \) are incomparable.

5. Branching degrees above low degrees. In this section we use the technique of Robinson described in §4 to show that the construction of Theorem 3.1 can be carried out above a given low r.e. degree. We thereby simultaneously show that there is a branching degree above any given low r.e. degree and strengthen the positive answer to the generalized nondiamond question given by Shoenfield and Soare, and Lachlan.

Let \( d \) be a low r.e. degree and \( D \) be an r.e. set in \( d \). We wish to show that there are r.e. degrees \( c, a_0, \) and \( a_1 \) with \( d \leq c, a_0 \) and \( a_1 \) incomparable, \( c = a_0 \cap a_1 \) and \( 0' = a_0 \cup a_1 \). We will construct r.e. sets \( C, A_0 \) and \( A_1 \) to meet, for all \( e \in \omega \) and \( /' = 0 \) or \( 1 \), requirements

\[
N_e: \Theta^0_e(A_0, C, D) = \Theta^1_e(A_1, C, D) = f, \text{ } f \text{ } \text{total} \rightarrow f \leq_T C,
\]

and

\[
R'_e: \Phi_e(C, D) \neq A_i,
\]

where \( \langle \Theta^0, \Theta^1 \rangle \) is an effective enumeration of all pairs of partial recursive functionals of three set variables. We will then set

\[
c = \deg(C \oplus D) \quad \text{and} \quad a_i = \deg(A_i \oplus C \oplus D).
\]

Let \( (R_n)_{n \in \omega} \) be an effective listing of the \( R'_e \)’s.

We meet the \( N_e \) requirements as in the proof of Theorem 3.1, i.e., \( N_e \) works on \( 2^e \) reductions \( A^e \), one for each string \( a \) with \( \text{lha} = e + 1 \) and \( a(e) = 0 \). Also as in the proof of Theorem 3.1 each \( R_n \) has \( 2^n \) strategies, one for each string \( a \) with \( \text{lha} = n \). A strategy \( a \) attempts to win \( R_{\text{lha}} \) by diagonalizing on a witness \( x_a \). In the proof of Theorem 4.2, when \( R_n \) sees a computation on its witness \( x_n \) against which it wishes to diagonalize, it uses its oracle procedure to ask whether \( D \) is correct through the use in the computation. If the oracle procedure gives a positive answer an attack is made; if the answer is negative, the computation can be ignored because it is not correct. In the construction under discussion we define a set \( \hat{D} \) which is a speeded-up enumeration of \( D \). If strategy \( a \) sees at stage \( s \) a computation \( \Phi_e(C, \hat{D}; x_a) = 0 \)
against which it wishes to diagonalize (say $R_{\text{tha}}$ is $R_e^i$), it is not sufficient to ask the oracle procedure if $\hat{D}$ is correct through the use in this computation. For there may be a marker $\lambda^\gamma_m$, with $\gamma \subseteq \alpha$, whose value is less than the use $\varphi_e(C, \hat{D}; x_\alpha)$, but with $\Theta_{\text{hyr}}^{-i}(A_{1-i}, C, \hat{D}; m)$ very large. Then, even though $\hat{D}$ is correct on the use $\varphi_e(C, \hat{D}; x_\alpha)$, at some later stage a number $< \Theta_{\text{hyr}}^{-i}(A_{1-i}, C, \hat{D}; m)$ but $\geq \varphi_e(C, \hat{D}; x_\alpha)$ may enter $\hat{D}$, thereby destroying the computation $\Theta_{\text{hyr}}^{-i}(A_{1-i}, C, \hat{D}; m)$. Then strategy $\gamma$ may have to put $\lambda^\gamma_m$ into $C$ and destroy the computation against which $\alpha$ is trying to diagonalize. Thus when $\alpha$ wishes to diagonalize at stage $s$, it asks the oracle procedure whether $\hat{D}$ is correct through $s$. If the oracle procedure gives a positive answer, then an attack is made, while if the answer is negative, then a number $< s$ has entered $\hat{D}$ and we repeat the process, using whatever strategies now look correct.

We now give the complete proof.

**Theorem 5.1.** If $d$ is a low r.e. degree, then there are r.e. degrees $c, a_0$, and $a_1$ such that $d = \leq c, a_0$, and $a_1$, are incomparable, $a_0 \cap a_1 = c$, and $\theta' = a_0 \cup a_1$.

**Proof.** Let $D$ be an r.e. set in $d$. We construct r.e. sets $C$, $A_0$, and $A_1$. For each $e \in \omega$ and $i = 0$ or $1$, we wish to meet $N_e$ and $R_e^i$ as given by (5.1) and (5.2). Let $\{R_e^i\}_{n \in \omega}$ be an effective listing of the $R_e^i$'s. If $R_{\text{tha}}$ is $R_e^i$, we write $\Phi_e$ for $\Phi_e$, $\varphi_e$ for $\varphi_e$ and $A_e$ for $A_e$. We have $x_a, A^a_m, \lambda^a_m$ as discussed previously.

As usual, we assume that we are given some standard effective stage-by-stage enumeration of $D$. In the course of the construction we define a set $\hat{D}$. The numbers put into $\hat{D}$ are exactly those numbers which are in $D$, put in in the same order as they appear in the standard enumeration of $D$. Substage 4 of the construction ensures that “in the limit,” i.e., at the end of the construction, $\hat{D}$ equals $D$, but, in general, at a given point in the construction, the numbers which we have put into $\hat{D}$ (by looking ahead in the enumeration of $D$) will not appear in $D$ until a much later stage. Thus $\hat{D}$ is the result of a “speeded-up” enumeration of $D$.

In our construction, substage 1 of stage $s$ will be divided into a varying number of subsubstages, each of which has two parts a and b. We write substage 1.t.a or 1.t.b for parts a or b of subsubstage t of substage 1. We also let $u_s$ be the last subsubstage of substage 1 of stage $s$.

During stage $s$ of the construction we define

\[ l(e) = \max\{x: (\forall y < x)[\Theta^i_e(A_0, C, \hat{D}; y) = \Theta^i_e(A_1, C, \hat{D}; y)]\}, \]

and we define inductively $\beta \in 2^\omega$ by

\[ \beta(e) = 0 \leftrightarrow (\forall t)[(e \leq t < s \land \beta_t \uparrow e = \beta \uparrow e) \rightarrow l(e)[t, 1.u_s.b] < l(e)], \]

where $\beta_t$ is a string of length $t$ defined at stage $t$.

At any point in the construction we say that $\alpha$ requires attention for $R_{\text{tha}}$ if either

\[ x_\alpha \text{ is undefined}, \]

or

\[ x_\alpha \text{ is defined, } x_\alpha \not\in A_\alpha \text{ and } \Phi_\alpha(C, \hat{D}; x_\alpha) = 0. \]
If at some point in the construction we have \( x_\alpha \) defined with \( x_\alpha \in A_\alpha \) and \( \Phi_\alpha(C, \tilde{D}; x_\alpha) \) does not converge to 0, we cancel \( x_\alpha \).

Since \( D \) is low, there is a recursive function \( f \) satisfying (4.1) and (4.2). From time to time during the construction a strategy \( \alpha \) for \( R_{\text{tha}} \) wishes to know if \( \bar{\delta}_x \subseteq \tilde{D} \), so enumerates \( x \) into a set. We assume, by the recursion theorem, that for each \( \alpha \) we know the index \( j_\alpha \) such that \( W_{j_\alpha} \) equals the set of canonical indices about which \( \alpha \) asks.

Let \( K \) be an r.e. set of degree \( \Theta' \) and let \( \{k_s\}_{s \in \omega} \) be a one-one recursive enumeration of \( K \).

We now present the construction.

**Stage s. Substage 1.** Set \( t = 0 \).

**Substage 1.**

**Substage 1.a.** For each \( \alpha \) and \( n \) such that \( \lambda_n^\alpha \) is defined, if neither \( \Theta_{\text{tha}-1}^0(A_0, C, \tilde{D}; n) \) nor \( \Theta_{\text{tha}-1}^1(A_1, C, \tilde{D}; n) \) converges to \( \Lambda_n^\alpha \), then enumerate \( \lambda_n^\alpha \) into \( C \) and cancel \( \lambda_n^\alpha \) and \( \Lambda_n^\alpha \). Repeat this process until for every \( \lambda_n^\alpha \) which is defined at least one of \( \Theta_{\text{tha}-1}^0(A_0, C, \tilde{D}; n) \) and \( \Theta_{\text{tha}-1}^1(A_1, C, \tilde{D}; n) \) converges to \( \Lambda_n^\alpha \).

**Substage 1.b.** Let \( \beta_{s,t} \) be the current value of \( \beta \) restricted to \( s \). See if, for any \( n < s, \beta_{s,t} \) requires attention for \( R_n \). If not, then substage 1 is over. If so, let \( n \) be the least such and set \( \alpha = \beta_{s,t} \uparrow n \). If \( x_\alpha \) is undefined, let \( x_\alpha \) be \( 2s + 1 \); then \( \alpha \) receives attention at stage \( s \) for \( R_n \) and substage 1 is over. Otherwise, let \( \bar{\delta}_x = \tilde{D} \uparrow s \), enumerate \( x \) into \( W_{j_\alpha} \), and then simultaneously enumerate new elements from \( D \) into \( \tilde{D} \) and search for \( x \) in \( W_{j_\alpha} \). Either an element of \( \bar{\delta}_x \) will appear in \( \tilde{D} \) or else \( x \) will appear in \( W_{j_\alpha} \). Stop the searches when one of these two events occurs. If the former occurs first, increase \( t \) by 1 and begin subsubstage \( t \). Otherwise, enumerate \( x_\alpha \) into \( A_\alpha \), cancel all \( \lambda_m^\alpha \), \( \Lambda_m^\alpha \) and \( x_\alpha \) with \( \alpha < \alpha' \), and enumerate a restraint of priority \( \alpha \) equal to \( s \); \( \alpha \) receives attention at stage \( s \) and substage 1 is over.

Let \( u_s \) be the final subsubstage of substage 1, and let \( \beta_s = \beta_{s,u_s} \).

**Substage 2.** For each \( e < s \) such that \( \beta_e(e) = 0 \), find the least \( p < l(e)[s, 1, u_s, b] \), if any, such that \( \Theta_\alpha^0(A_0, C, \tilde{D}; p) = \Theta_\alpha^1(A_1, C, \tilde{D}; p) = q \), say, and \( \lambda_p^{\beta_e e+1} \) is undefined and then define \( \lambda_p^{\beta_e e+1} \) to be a number larger than any used in the construction so far and define \( \Lambda_p^{\beta_e e+1} = q \).

**Substage 3.** Find the least \( a_s \), if any, such that \( 2 \cdot k_s \) is < a restraint of priority \( \alpha \). If this \( a_s \) exists, put \( 2 \cdot k_s \) into \( A_{a_s} \). Otherwise, put \( 2 \cdot k_s \) into \( A_0 \).

**Substage 4.** Enumerate a new element from \( D \) into \( \tilde{D} \).

Note that if \( t \) is not the final subsubstage of substage 1 of stage \( s \), then during substage 1.t.b of stage \( s \) a number < \( s \) is enumerated into \( \tilde{D} \). Thus for each \( s \), there are only finitely many subsubstages in substage 1 of stage \( s \).

**Lemma 1.** \( K \leq_T A_0 \oplus A_1 \).

**Proof.** We have \( x \in K \leftrightarrow 2x \in A_0 \cup A_1 \).

For each \( n \), let \( \delta_n \) be the least string of length \( n \) which is equal to \( \beta_{s \uparrow n} \) for infinitely many \( s \geq n \). Then for all \( n \), \( \delta_n \subseteq \delta_{n+1} \), as in the proof of Theorem 3.1.

**Lemma 2.** For all \( n \), \( R_n \) is met and \( \delta_n \) receives attention only finitely often.
Proof. Suppose that the result holds for \( n' < n \). Let \( q \) be the largest restraint of priority \( < \delta_n \) put on during the construction. Take \( s_0 \geq n \) so large that (3.4), (3.5), and (3.6) are satisfied. Let \( A_{\delta_n} \) be \( A_i \). Then, by (3.6), at no stage \( s \geq s_0 \) does \( 2 \cdot k_s \) enter \( A_{1-s} \) if \( 2 \cdot k_s \) is less than a restraint of priority \( \delta_n \) which exists at substage 3 of stage \( s \). Also

\[
\text{if } s \geq s_0 \text{ and } \delta_n \subseteq \beta_s, \text{ then at substage 1.} u_s \text{ either } \delta_n \text{ does not require attention for } R_n \text{ or else } \delta_n \text{ receives attention for } R_n.
\]

To see (5.5), note that at substage 1.\( u_s \), either no initial segment of \( \beta_{s, u_s} = \beta_s \) requires attention, so \( \delta_n \) does not require attention, or else some initial segment \( a \) of \( \beta_s \) receives attention. In the latter case, if \( a \subset \delta_n \), then \( a = \delta_n \), \( n' = lha < n \), and this contradicts (3.4). If \( a = \delta_n \), then (5.5) holds. If \( a \subset \delta_n \), then we must have \( \delta_n \) does not require attention at substage 1.\( u_s \) (else \( a \) would not receive attention), so again (5.5) holds.

Now suppose that at stage \( s \geq s_0 \), \( x_{\delta_n} \) is put into \( A_{\beta_n} = A_i \) at substage 1.\( u_s \). Then we claim that the first change in \( A_{1-s} \cup C \cup D \) below \( s \) at or after substage 1.\( u_s \) of stage \( s \) is a change in \( D \). The proof is similar to the proof of the corresponding claim in Lemma 2 of Theorem 3.1. Let \( w \) be the first number \( < s \) to enter \( A_{1-s} \cup C \cup D \) at or after substage 1.\( u_s \) of stage \( s \), say \( w \) enters at stage \( t \geq s \). We can rule out \( w = 2 \cdot k_s \), since a restraint of priority \( \delta_n \) equal to \( s \) is enumerated at substage 1.\( u_s \) of stage \( s \). By cancellation and (3.4), \( w = x_a \) for some \( a \) is ruled out. If \( w = \lambda^a_m \), then by (3.5) and cancellation we have \( \alpha \subseteq \delta_n \subseteq \beta_{s, u_s} \), so \( \beta_{s, u_s} (lha - 1) = 0 \). Since \( w \) equalled \( \lambda^a_m \) before stage \( s \), \( m < l(lha - 1) \), so both \( \Theta_{lha-1}^0 (A_0, C, \bar{D}; m) [s, 1. u_s, b] \) and \( \Theta_{lha-1}^1 (A_1, C, \bar{D}; m) [s, 1. u_s, b] \) converge to a common value, \( z \), say, and \( \lambda^a_m [s, 1. u_s, b] = z \), so before \( w \) is put into \( C \) at stage \( t \), a number \( < \theta_{lha-1}^i (A_{1-s}, C, \bar{D}; m) [s, 1. u_s, b] < s \) must enter \( A_{1-s} \cup C \cup D \). But then \( w \) was not the first number \( < s \) to enter \( A_{1-s} \cup C \cup D \) at or after substage 1.\( u_s \) of stage \( s \). Thus \( w \) must enter \( D \).

Next, suppose that at stage \( s \geq s_0 \) a number \( x \) is put into \( W_{j_{n_x}} \) and \( \cap_j C \subseteq \bar{D} \). Then \( x_{\delta_n} \) is put into \( A_i \) at stage \( s \) and by the preceding paragraph and the fact that \( C \subseteq \bar{D} \), the computation \( \Phi_{\delta_n} (C, \bar{D}; x_{\delta_n}) [s, 1. u_s, b] = 0 \) is correct. Hence \( x_{\delta_n} \) is never canceled and \( \delta_n \) never later requires attention, so no further numbers are put into \( W_{j_{n_x}} \). Thus \( W_{j_{n_x}} \cap \{ x: \cap_j C \subseteq \bar{D} \} \) is finite, so by (4.2), \( W_{f(j_{n_x})} \) is finite.

Suppose that \( x_{\delta_n} \) is put into \( A_i \) at stages \( s_1 \) and \( s_2 \) with \( s_2 > s_1 \geq s_0 \). Then for \( r = 1 \) or \( 2 \), at stage \( s_r \), \( y_r \) is put into \( W_{j_{n_x}} \) where \( \cap_y C \subseteq \bar{D} [s_r, 1. u_s, b] \) and \( y_r \in W_{f(j_{n_x})} \). After \( x_{\delta_n} \) is put into \( A_{\delta_n} \) at stage \( s_1 \), as long as no element of \( \cap_y C \) appears in \( \bar{D} \), \( \delta_n \) does not require attention for \( R_n \), so \( \cap_y C \subseteq \bar{D} [s_2, 1. u_s, b] \) and \( y_1 \neq y_2 \). Since \( W_{f(j_{n_x})} \) is finite, it follows that for some \( t_0 > s_0 \), \( x_{\delta_n} \) is not put into \( A_i \) at a stage \( \geq t_0 \). Hence if \( \delta_n \) receives attention for \( R_n \) at a stage \( \geq t_0 \), a value is appointed to \( x_{\delta_n} \) at that stage. This value is not in \( A_i \) and will never be put in, so by (3.4), \( x_{\delta_n} \) is never canceled from this value, so \( \delta_n \) never later receives attention. Thus \( \delta_n \) receives attention only finitely often.
To see that $R_n$ is met, note that if $x_{\delta_n}$ were eventually permanently undefined, then $\delta_n$ would require attention through (5.3) cofinitely through the construction. Since there are infinitely many $s$ with $\beta_s \upharpoonright n = \delta_n$, this would contradict (5.5), so $x_{\delta_n}$ has a final value. If this final value is in $A_j$, then we cannot have $\Phi_{\delta_n}(C, D; x_{\delta_n}[\omega]) = 1$, else $x_{\delta_n}$ would be canceled from its final value, so $R_n$ is won on $x_{\delta_n}[\omega]$. If this final value is not in $A_j$, then we cannot have $\Phi_{\delta_n}(C, D; x_{\delta_n}[\omega]) = 0$, else at some large enough stage $s$ with $\delta_n \subseteq \beta_s$, $\delta_n$ would require attention throughout stage $s$ by (5.4), again contradicting (5.5). Thus $R_n$ is won on $x_{\delta_n}[\omega]$. □

**Lemma 3.** For all $e$, $N_e$ is met.

**Proof.** The proof is virtually the same as the proof of Lemma 3 of Theorem 3.1. □

The theorem follows from the lemmas, for if

$$c = \deg(C \oplus D) \quad \text{and} \quad a_i = \deg(A_i \oplus C \oplus D)$$

for $i = 0$ or 1, then by Lemma 1, $0' = a_0 \cup a_1$, by Lemma 2, $a_0$ and $a_1$ are $> c$, and by Lemma 3, $a_0 \cap a_1 = c$. ■

The "diamond lattice" is the four-element lattice with two incomparable elements. As immediate corollaries of Theorem 5.1 we have

**Corollary 5.2.** If $d$ is a low r.e. degree, then there is a branching degree $c$ with $d < c$. ■

**Corollary 5.3.** The diamond lattice can be embedded into the r.e. degrees above any given low r.e. degree, with greatest element preserved. ■

Corollary 5.3 extends the result of Shoenfield and Soare, and Lachlan, giving a positive answer to the generalized nondiamond question.

We would now like to strengthen Theorem 5.1 by adding avoiding a cone, i.e., in the notation of that theorem, if $b$ is a degree with $b \nleq d$, then we would like to add to the conclusion that $b \nleq c$. With this strengthened theorem we can deduce that the branching degrees form an automorphism base for the r.e. degrees and that, given an incomplete, nonzero r.e. degree, there is a branching degree incomparable with the given degree. If $b \nleq 0'$, then $b \nleq c$ is automatic, so we may take $b \leq 0'$. Let $B \in b$. Then by Shoenfield's Limit Lemma [8, p. 29], there is a recursive sequence of finite sets $\{B_s\}_{s \in \omega}$ which converges to $B$. When we refer to $B$ during stage $s$, we mean $B_s$. The usual avoiding the cone technique is that of Sacks negative restraint. For each $e$ we have the requirement

$$S_e: \Phi_e(C, D) \neq B.$$ 

For the Sacks negative restraint technique to work, $B$ must not be recursive in the injury set to $S_e$. The usual way to ensure this would be for the set put into $C$ for sake of any given $N_e$ to be recursive in $D$. However, $C$ itself can be recursive in the set put into $C$ for sake of a single $N_e$ and in general $D \sim T C$. Hence the Sacks strategy cannot be used without modification; nevertheless, the basic idea behind our strategy is the same as that of the Sacks strategy.
Each $S_e$ has $2^e$ strategies, one for each string $a$ of length $e$. Strategy $\alpha$ is played when $\alpha$ looks like the correct guess; if $lha = e$ and $y$ is $< e$ the length of agreement between $B$ and $\Phi_e(C, \hat{D})$ at stage $s$, then strategy $\alpha$ wants to verify the computation $\Phi_e(C, \hat{D}; y)$ by asking the oracle procedure if $\hat{D}$ is correct through $s$. If a positive answer is given, strategy $\alpha$, through cancellation and restraint ensures that the apparent computation $\Phi_e(C, \hat{D}; y)$ is correct unless the oracle’s answer is false. If $S_e$ fails, then for every $y$ a $\hat{D}$-correct computation $\Phi_e(C, \hat{D}; y)$ becomes verified by $\delta_e$ and then $B \leq_T D$, a contradiction. Here are the details.

**Theorem 5.4.** If $d$ is a low r.e. degree and $b \not\leq d$, then there are r.e. degrees $c, a_0,$ and $a_1$ with $d < c$, $b \not\leq c$, $a_0$ and $a_1$ incomparable, $a_0 \cap a_1 = c$, and $a_0 \cup a_1 = \emptyset'$.

**Proof.** We indicate only the modifications which must be made to the proof of Theorem 5.1. Let $B \in b$. We may assume $b \not\leq \emptyset'$ (else $b \not\leq c$ is automatic) so there is a recursive sequence $\{B_s\}_{s \in \omega}$ of finite sets converging to $B$. When we refer to $B$ during stage $s$, we mean $B_s$.

We have for each $e$ requirement $S_e$ given by (5.6). Each string $a$ of length $e$ besides being a strategy for $R_e$ is also a strategy for $S_e$. We say that $\alpha$ requires (receives) attention for $R_e$ ($S_e$) if strategy $\alpha$ for $R_e$ ($S_e$) requires (receives) attention. If $\alpha$ requires (receives) attention for either $R_e$ or $S_e$, then we say that $\alpha$ requires (receives) attention. When $\alpha$ receives attention for $S_e$, it does so through a certain number $y$. At this time $\langle \alpha, y \rangle$ becomes verified and a number is specified such that if $C \cup \hat{D}$ later changes below this number, then $\langle \alpha, y \rangle$ becomes unverified; $\langle \alpha, y \rangle$ remains verified until such a change occurs.

At any point during the construction we let

$$l^B(e) = \max\{x: (\forall y < x)[\Phi_e(C, \hat{D}; y) = B(y)]\}$$

and we say that $\alpha$ requires attention for $S_{lha}$ if there is a $y < l^B(lha)$ with $\langle \alpha, y \rangle$ unverified.

From time to time during the construction a strategy $\alpha$ for $S_{lha}$ wants to know, for sake of some $y$, if $\bigcup_x \subseteq \hat{D}$, so enumerates $x$ into a set. We assume, by the recursion theorem, that for each $\alpha$ and $y$ we know the index $\nu_{(\alpha,y)}$ such that $W_{\nu_{(\alpha,y)}}$ equals the set of canonical indices about which strategy $\alpha$ for $S_{lha}$ asks for sake of $y$.

The construction is identical to that of Theorem 5.1, except for substage 1.t.b which we give here.

**Substage 1.t.b.** Let $\beta_{s,t}$ be the current value of $\beta$ restricted to $s$. See if for any $n < s$, $\beta_{s,t} \uparrow n$ requires attention. If not, then substage 1 is over. If so, let $n$ be the least such and set $\alpha = \beta_{s,t} \uparrow n$. If $\alpha$ requires attention for $R_n$, then proceed as before. Otherwise $\alpha$ requires attention for $S_n$. Let $y$ be the least number $< l^B(n)$ such that $\langle \alpha, y \rangle$ is unverified, and let $\bigcup_x = \hat{D} \uparrow s$. Enumerate $x$ into $W_{\nu_{(\alpha,y)}}$ and then simultaneously enumerate new elements from $D$ into $\hat{D}$ and search for $x$ in $W_{\nu_{(\alpha,y)}}$. Either an element of $\bigcup_x$ will appear in $\hat{D}$ or else $x$ will appear in $W_{\nu_{(\alpha,y)}}$. Stop the searches when one of these events occurs. If the former happens first, increase $t$ by 1 and begin subsstage $t$. Otherwise declare $\langle \alpha, y \rangle$ to be verified until $C \cup \hat{D}$ changes below $s$, cancel all $\lambda'_n$, $\Lambda'_n$, and $\pi_n$ with $\alpha < \alpha'$, and enumerate a restraint of priority $\alpha$ equal to $s$; $\alpha$ receives attention for $S_n$ at stage $s$ and substage 1 is over. □
Again, if \( t \) is not the final subsubstage of substage 1 of stage \( s \), then a number \(< s \) is enumerated into \( \hat{D} \) during substage 1.r.b of stage \( s \), so for all \( s \) there are only finitely many subsubstages in substage 1 of stage \( s \).

**Lemma 1.** \( K \leq TA_0 \oplus A_1 \). \( \Box \)

Define \( \delta_n \) as before. Then for all \( n \), \( \delta_n \subseteq \delta_{n+1} \).

**Lemma 2.** For each \( n \),
1. \( R_n \) is met and \( \delta_n \) receives attention for \( R_n \) only finitely often, and
2. \( S_n \) is met and \( \delta_n \) receives attention for \( S_n \) only finitely often.

**Proof.** Suppose that the result holds for all \( n' < n \). The proof of (i) is as before. Assuming that (i) holds for \( n \), we may take \( s_0 \geq n \) such that (3.4), (3.5), and (3.6) are satisfied and, in addition,

\[
(5.7) \quad s \geq s_0 \rightarrow \delta_n \text{ does not receive attention for } R_n \text{ at stage } s. 
\]

Corresponding to (5.5) we now have

\[
(5.8) \quad \text{if } s \geq s_0 \text{ and } \delta_n \subseteq B, \text{ then at substage } 1.u.s.b \text{ either } \delta_n \text{ does not require attention for } S_n \text{ or else } \delta_n \text{ receives attention for } S_n. 
\]

Let \( A_\delta = A_\iota \). Suppose that at stage \( s \geq s_0 \), \( \delta_n \) receives attention for \( S_n \) through \( y \). Then we claim that the first change in \( A_\iota \cup C \cup \hat{D} \) below \( s \) at or after substage 1.u.s.b of stage \( s \) is a change in \( \hat{D} \). The proof of this claim is as before.

Next suppose that for some \( y \) a number \( x \) with \( \bar{\delta}_x \subseteq \hat{D} \) is put into \( W_{v(\delta_n, y)} \) at stage \( s \geq s_0 \). Then \( \langle \delta_n, y \rangle \) is declared verified at stage \( s \) and \( \hat{D} \uparrow s[1, 1.u.s.b] = \hat{D} \uparrow s \), so by the previous claim \( C \cup \hat{D} \uparrow s[1, 1.u.s.b] = C \cup \hat{D} \uparrow s \). Hence \( \langle \delta_n, y \rangle \) remains verified throughout the rest of the construction and no further numbers are put into \( W_{v(\delta_n, y)} \).

It follows that

\[
W_{v(\delta_n, y)} \cap \{ x : \bar{\delta}_x \subseteq \hat{D} \} 
\]

is finite, so \( W_{f(v(\delta_n, y))} \) is finite for each \( y \).

Suppose that \( \delta_n \) receives attention for \( S_n \) through \( y \) at stages \( s_1 \) and \( s_2 \) with \( s_2 > s_1 \geq s_0 \). Then for \( r = 1 \) or 2, at stage \( s_r \), \( x_r \) is put into \( W_{v(\delta_n, y)} \) where \( \bar{\delta}_{x_r} \subseteq \hat{D}[s_r, 1.u.s.b] \) and \( x_r \in W_{f(v(\delta_n, y))} \). As long as no element of \( \bar{\delta}_{x_1} \) appears in \( \hat{D} \), \( \langle \delta_n, y \rangle \) remains verified, so \( \bar{\delta}_{x_1} \not\subseteq \hat{D}[s_2, 1.u.s.b] \) and \( x_1 \neq x_2 \). Since, for all \( y \), \( W_{f(v(\delta_n, y))} \) is finite, for all \( y \), \( \delta_n \) receives attention for \( S_n \) through \( y \) only finitely often. Thus for each \( y \), \( \langle \delta_n, y \rangle \) is either eventually permanently verified or eventually permanently unverified.

Now suppose that \( S_n \) fails, so \( \Phi_n(C, D) = B \). Then we claim that for all \( y \), \( \langle \delta_n, y \rangle \) is eventually permanently verified. Suppose not. Take \( y_0 \) least such that \( \langle \delta_n, y_0 \rangle \) is eventually permanently unverified. Let \( s_1 \geq s_0 \) be such that

\[
(5.9) \quad \langle \delta_n, y_0 \rangle \text{ is permanently unverified by the beginning of stage } s_1, 
\]

\[
(5.10) \quad y < y_0 \rightarrow \langle \delta_n, y \rangle \text{ is permanently verified by the beginning of stage } s_1, 
\]

and

\[
(5.11) \quad y_0 < l^B(n) \text{ throughout all stages } s \geq s_1. 
\]
Let $s \geq s_1$ be such that $\beta_s \parallel n = \delta_n$. Then by (5.9) and (5.11), $\delta_n$ requires attention for $S_n$ throughout stage $s$, so by (5.8) $\delta_n$ receives attention for $S_n$ at stage $s$. By (5.9)–(5.11), $\delta_n$ receives attention for $S_n$ through $y_0$ at stage $s$, contradicting (5.9). This proves the claim.

Now let $y$ be such that $\delta_n$ does not receive attention for $S_n$ through $y$ prior to stage $s_0$ (this is true for almost all $y$). Then by the previous claim, at some stage $s \geq s_0$, $\delta_n$ receives attention for $S_n$ through $y$ at stage $s$ and $\langle \delta_n, y \rangle$ remains verified throughout the rest of the construction. Thus, given a $D$ oracle and such a $y$, we may successfully search for a stage $s \geq s_0$ such that $\delta_n$ receives attention for $S_n$ through $y$ at stage $s$ and $\hat{D} \upharpoonright s[s, 1, u_x, b] = \hat{D} \upharpoonright s$. By an earlier claim we in fact have $C \cup \hat{D} \upharpoonright s[s, 1, u_x, b] = C \cup \hat{D} \upharpoonright s$ so since $\Phi_n(C, \hat{D}; y)[s, 1, u_x, b]$, $B(y) = \Phi_n(C, \hat{D}; y) = \Phi_n(C, \hat{D}; y)[s, 1, u_x, b]$, where $s$ was found effectively in $D$. Thus $B \leq_T D$, contradicting $b \notin d$. Hence $S_n$ is met.

It remains to show that $\delta_n$ receives attention for $S_n$ only finitely often. Since $S_n$ holds, let $p = \mu p'[\neg(\Phi_n(C, D; p') = B(p'))]$. Then $\langle \delta_n, p \rangle$ is either eventually permanently verified or eventually permanently unverified. If $\langle \delta_n, p \rangle$ is eventually permanently verified, then $\Phi_n(C, D; p)[\omega] \upharpoonright \neq B(p)$, so throughout all sufficiently large stages $l^p(n) = p$. Thus for all sufficiently large $s$, if $\delta_n$ receives attention for $S_n$ through $y$ at stage $s$, then $y < p$. But we already know that for any fixed $y$, $\delta_n$ receives attention for $S_n$ through $y$ only finitely often, so in this case $\delta_n$ receives attention for $S_n$ only finitely often. If $\langle \delta_n, p \rangle$ is eventually permanently unverified, then once $\langle \delta_n, p \rangle$ is permanently unverified, $\delta_n$ cannot receive attention for $S_n$ through any $y > p$. Hence again $\delta_n$ receives attention for $S_n$ only finitely often and the lemma is established. □

**Lemma 3.** For all $e$, $N_e$ is met.

**Proof.** The proof is exactly the same as that of Lemma 3 of Theorem 5.1. □

The theorem follows from the lemmas. Let

$$c = \deg(C \oplus D) \quad \text{and} \quad a_i = \deg(A_i \oplus C \oplus D)$$

for $i = 0$ and 1. Then by Lemma 1, $\theta^* = a_0 \cup a_1$, by Lemma 2, $a_i > c$ for $i = 0$ and 1 and $b \leq c$, and by Lemma 3, $c = a_0 \cap a_1$. □

An automorphism of the r.e. degrees is a map $\Theta$ taking r.e. degrees to r.e. degrees such that $\Theta$ is a bijection and for all r.e. degrees $a$ and $b$, $a \leq b \leftrightarrow \Theta(a) \leq \Theta(b)$. A set $S$ of r.e. degrees is called an automorphism base for the r.e. degrees if any two automorphisms of the r.e. degrees which agree on $S$ are necessarily the same automorphism.

**Corollary 5.5.** The branching degrees are an automorphism base for the r.e. degrees.

**Proof.** It is easily seen that a set $S$ of r.e. degrees is an automorphism base for the r.e. degrees iff the only automorphism of the r.e. degrees which fixes each element of $S$ is the identity map. By the Sacks Splitting Theorem, as given in [10], the low r.e.
degrees generate the r.e. degrees under join, so form an automorphism base for the r.e. degrees.

Suppose that \( \Theta \) is an automorphism of the r.e. degrees which fixes each branching degree. We want to show that \( \Theta \) is the identity. It suffices to show that \( \Theta \) fixes each low r.e. degree. Suppose for a contradiction that for some low r.e. degree \( d \), \( \Theta(d) \neq d \). If \( \Theta(d) \downarrow d \), let \( \overline{\Theta} = \Theta \) and \( \overline{d} = d \). If \( \Theta(d) \downarrow d \), then in fact \( \Theta(d) < d \); take \( \overline{\Theta} = \Theta^{-1} \) and \( \overline{d} = \Theta(d) \). Then in either case, \( \overline{\Theta} \) is an automorphism of the r.e. degrees which fixes each branching degree and \( \overline{d} \) is a low r.e. degree such that \( \overline{\Theta}(d) \downarrow \overline{d} \). By Theorem 5.4, there is a branching degree \( c \) with \( \overline{d} \leq c \) and \( \overline{\Theta}(d) \downarrow c \). Then \( \overline{\Theta}(d) \leq \overline{\Theta}(c) = c \), giving the desired contradiction. ■

**Corollary 5.6.** For each r.e. degree \( b \) with \( 0 < b < 0' \), there is a branching degree \( c \) with \( b \mid c \) (i.e., \( b \parallel c \) and \( c \parallel b \)).

**Proof.** Since \( 0 < b < 0' \), there is a low r.e. degree \( d \) with \( b \mid d \). (This fact follows, nonuniformly in an r.e. index for a set in \( b \), from the version of the Sacks Splitting Theorem given in [10, Theorem 1.2 and Remark 4.5].) By Theorem 5.4, there is a branching degree \( c \) with \( d \leq c \) and \( \overline{\Theta}(d) \downarrow c \). We must also have \( c \parallel b \), else \( d \leq c \leq b \), so \( b \mid c \), as desired. ■
