THE DIVISOR CLASSES OF THE HYPERSURFACE
\[ z^{p^n} = G(x_1, \ldots, x_n) \] IN CHARACTERISTIC \( p > 0 \)

BY

JEFFREY LANG

ABSTRACT. In this article we use P. Samuel's purely inseparable descent techniques to study the divisor class groups of normal affine hypersurfaces of the form \( z^p = G(x_1, \ldots, x_n) \) and develop an inductive procedure for studying those of the form \( z^{p^n} = G \). We obtain results concerning the order and type of these groups and apply this theory to some specific examples.

Introduction. In this article we study the divisor class group of normal affine hypersurfaces \( F_m \subset \mathbb{A}^{n+1}_k \) defined by equations of the form \( z^{p^n} = G(x_1, \ldots, x_n) \), where the ground field \( k \) is assumed to be algebraically closed of characteristic \( p > 0 \).

O. Zariski briefly considered surfaces of this type for the case \( m = 1, n = 2 \) in [ZA]. Investigations of their geometry have been made by P. Blass [B1, B2], who introduced me to this project. P. Samuel in his 1964 Tata notes [SI] describes the class group of several of these surfaces, such as \( z^p = xy \) and \( z^p = x^i + y^i \). Results from Samuel's notes and R. Fossum's book [FO] form the foundation of this work, and a brief discussion of these appears in §1.

Facts concerning the order and type of the class group of \( F_i; z^p = G(x_1, \ldots, x_n) \) appear in §2, together with the calculation of \( z^p = H(x_1, \ldots, x_n) \), where \( H \) is a form of degree not divisible by \( p \).

The case \( m > 1 \) is attacked in §3. K. Baba in [BA] uses higher derivations to study the class group of the hypersurfaces. We develop an alternate, inductive method of attacking \( \text{Cl}(F_m; z^{p^m} = G) \). Again we collect results about the order and type of these groups, ending this section with some examples.

In §4 the local behavior of \( \text{Cl}(F_i; z^p = G(x_1, x_2)) \) is discussed. In §5 a description of the class group of Krull rings \( A \) such that \( k[x_1^{p^m}, \ldots, x_n^{p^m}] \subset A \subset k[x_1, \ldots, x_n] \) is given.

0. Notation. 0.1. \( k \)-algebraically closed field of characteristic \( p > 0 \), unless stated otherwise.

0.2. \( \mathbb{A}^n_k \)-affine \( n \)-space over \( k \).

0.3. Surface-irreducible, reduced, two-dimensional, quasiprojective variety over \( k \).

0.4. The notation \( F; f(x_1, \ldots, x_n) = 0 \) means

\[ F = \text{Spec} \left( \frac{k[x_1, \ldots, x_n]}{(f(x_1, \ldots, x_n))} \right); F \subset \mathbb{A}^n_k. \]
0.5. If $A$ is a Krull ring we denote by $\text{Cl}(A)$ the divisor class group of $A$.

0.6. If $F$ is a surface we denote by $\text{Cl}(F)$ the divisor class group of the coordinate ring of $F$.

0.7. For $f(x_1, \ldots, x_n) \in k[x_1, \ldots, x_n]$ we denote by:
- $\text{deg } f$ — the total degree of $f$.
- $\text{deg}_{x_i} f$ — the degree of $f$ in $x_i$.
- $\text{deg}_{x_i, x_j} f$ — the degree of $f$ in the variables $x_i$ and $x_j$.

1. Preliminaries. P. Samuel's 1964 Tata notes [S1] and R. Fossum's *The divisor class group of a Krull domain* [FO] form the framework for this article. What follows is a brief discussion of some results from these works. We begin with Samuel's notes.

**Definition.** Let $A$ be a domain. $A$ is a *Krull ring* if there exists a family $(v_i)_{i \in I}$ of discrete valuations of $\mathbb{q}(v_i)$ such that:

1. $A = \bigcap_i R_{v_i}$, where $R_{v_i}$ denotes the ring of $v_i$.
2. For every $x \neq 0 \in A$, $v_i(x) = 0$, for almost all $i \in I$.

**Theorem 1.1.** A Noetherian integrally closed domain is a Krull ring (see [S1, p. 5]).

**Definition.** Let $A$ be a domain with quotient field $K$. A *fractionary ideal* $a$ is an $A$-submodule of $K$ for which there exists an element $d \in A$ ($d \neq 0$) such that $da \subseteq A$. A fractionary ideal is called a *principal ideal* if it is generated by one element. $a$ is said to be *integral* if $a \subseteq A$. $a$ is said to be *divisorial* if $a \neq \{0\}$ and if $a$ is an intersection of principal ideals.

**Definition.** Let $I(A)$ denote the set of nonzero fractionary ideals of the domain $A$. On $I(A)$ we define an equivalence relation by $a \sim b \iff A: a = A: b$. The quotient set of $I(A)$ by this equivalence relation is called the set of *divisors* of $A$, denoted by $D(A)$. For each $a \in I(A)$, we denote by $\bar{a}$ the equivalence class of $a$ in $D(A)$.

**Definition.** Let $A$ be a Krull domain. The composition law $(a, b) \sim ab$ on $I(A)$ induces a well-defined operation on $D(A)$, thus giving $D(A)$ the structure of an abelian group with identity element $\bar{1}$ (see [S1, pp. 1–4]). Hereafter we will write this composition law additively. Thus $\bar{a} + \bar{b} = \bar{ab}$ for $\bar{a}, \bar{b} \in D(A)$. Let $F(A)$ denote the subgroup of $D(A)$ generated by the principal divisors (equivalence classes of principal ideals). We denote by $\text{Cl}(A)$ the quotient group $D(A)/F(A)$, called the *divisor class group* of $A$.

**Theorem 1.2.** Let $A$ be a Krull ring. Then:

1. $\text{Cl}(A)$ is generated by the classes of the height one primes of $A$.
2. $A$ is factorial if and only if $\text{Cl}(A) = 0$ (see [S1, pp. 6–7, 18]).

**Notation.** Let $A \subseteq B$ be rings. Let $p \subseteq A$ and $q \subseteq B$ be prime ideals. We write $q \mid p$ if $q \cap A = p$ and we say that $q$ lies over $p$.

**Theorem 1.3.** Let $A \subseteq B$ be Krull rings. Suppose that either $B$ is integral over $A$ or that $B$ is a flat $A$ algebra. Then there is a well-defined group homomorphism $\phi$: $\text{Cl}(A) \to \text{Cl}(B)$ (see [S1, pp. 19–20]).
Let us describe the homomorphism of Theorem 1.3. If \( q \) and \( p \) are height one primes of \( B \) and \( A \) with \( q | p \), we let \( e(q : p) \) denote the ramification index of \( q \) over \( p \). Then for each height one prime \( p \) of \( A \) we define \( \phi(p) = \sum_{q | p} e(q : p)p \), the sum taken over all height one primes in \( B \) lying over \( p \). This sum is always finite since \( B \) is a Krull ring. We then extend \( \phi \) by linearity. The hypotheses in Theorem 1.3 are needed to guarantee that this map induces a well-defined map on divisor classes.

**Theorem 1.4.** Let \( A \) be a Krull ring and \( S \) a multiplicatively closed subset in \( A \). Then \( S^{-1}A \) is an \( A \)-flat Krull ring and:

1. \( \phi : \text{Cl}(A) \to \text{Cl}(S^{-1}A) \) is surjective; and
2. if \( S \) is generated by prime elements then \( \phi \) is bijective (see [S1, p. 21]).

**Remark 1.5.** In Theorem 1.4, \( \ker \phi = H + F(A)/F(A) \), where \( H \subset D(A) \) is the subgroup generated by those height one primes \( p \) of \( A \) such that \( p \cap S \neq \emptyset \).

**Theorem 1.6.** Let \( R \) be a Krull ring. Then \( R[x] \) is a Krull ring and \( \phi : \text{Cl}(R) \to \text{Cl}(R[x]) \) is bijective [S1, p. 22].

Let \( A \) be a Noetherian ring and \( m \) an ideal contained in the Jacobson radical of \( A \). If we give \( A \) the \( m \)-adic topology, then \( (A, m) \) is called a Zariski ring. The completion \( \hat{A} \) of \( A \) will also be a Zariski ring and is \( A \)-flat with \( A \subset \hat{A} \).

**Theorem 1.7.** Let \( (A, m) \) be a Zariski ring. Then if \( \hat{A} \) is a Krull ring, so is \( A \). Also \( \phi : \text{Cl}(A) \to \text{Cl}(\hat{A}) \) is injective [S1, p. 23].

Throughout this article we will concentrate for the most part on the case where \( \text{qt}(B)/\text{qt}(A) \) is a purely inseparable extension. The following results are also from Samuel's notes.

We let \( B \) be a Krull ring of characteristic \( p > 0 \). Let \( \Delta \) be a derivation of \( \text{qt}(B) \) such that \( \Delta(B) \subset B \). Let \( K = \ker(\Delta) \) and \( A = B \cap K \). Then \( A \) is a Krull ring with \( B \) integral over \( A \). Thus we have a map \( \phi : \text{Cl}(A) \to \text{Cl}(B) \).

Set \( \hat{\mathcal{E}} = \{ t^{-1}\Delta t \mid t \in \text{qt}(B) \} \) and \( t^{-1}\Delta t \in B \). Note that \( \hat{\mathcal{E}} \) is an additive subgroup of \( B \), called the group of logarithmic derivatives of \( \Delta \). Set \( \hat{\mathcal{E}}' = \{ u^{-1}\Delta u \mid u \) is a unit in \( B \} \). Then \( \hat{\mathcal{E}} ' \) is a subgroup of \( \hat{\mathcal{E}} \).

**Theorem 1.8.** (a) There exists a canonical monomorphism \( \tilde{\phi} : \ker \phi \to \hat{\mathcal{E}}/\hat{\mathcal{E}}' \). (b) If \( [\text{qt}(B) : K] = p \) and \( \Delta(B) \) is not contained in any height one prime of \( B \), then \( \tilde{\phi} \) is an isomorphism [S1, p. 62].

**Theorem 1.9.** (a) If \( [\text{qt}(B) : K] = p \), then there exists \( a \in A \) such that \( \Delta^p = a\Delta \); (b) an element \( t \in B \) is in \( \hat{\mathcal{E}} \) if and only if \( \Delta^{p-1}(t) - at + t^p = 0 \) [S1, pp. 63–64].

**Remark 1.10.** We take a moment to describe the monomorphism \( \tilde{\phi} : \ker \phi \to \hat{\mathcal{E}}/\hat{\mathcal{E}}' \). Let \( \beta \in \ker \phi \subset \text{Cl}(A) \). Then \( \phi(\beta) = tB \) for some \( t \in \text{qt}(B) \). The map \( \tilde{\phi} \) sends \( \beta \) to \( t^{-1}\Delta t \).

To see that \( t^{-1}\Delta t \) is in \( B \), we write \( \beta \) as a linear combination of height one primes of \( A \), \( \beta = n_1q_1 + \cdots + n_rq_r \), where the \( q_i \) are height one primes of \( A \) and the \( n_i \) are integers. For each \( i \), there is a unique height one prime \( Q_i \) in \( B \) lying over \( q_i \). By definition \( \phi(\beta) = n_1e_1Q_1 + \cdots + n_re_rQ_r \), where \( e_i \) denotes the ramification index of
$Q$, $\phi(\beta) = tB$ implies that $B : Q_1^{1/e_1} \cdots Q_u^{1/e_u} = B : tB$. Thus for each height one prime $Q$ of $B$ the ramification index of $Q$ divides $v_Q(t)$ where $v_Q$ is the valuation corresponding to $Q$. It follows that there exists an $a \in K$ such that $v_Q(t) = v_Q(a)$, i.e. $t = au$ for $u$ a unit in $B_Q$. Thus $t^{-1}\Delta t = a^{-1}\Delta a + u^{-1}\Delta u = u^{-1}\Delta U$. Since $\Delta(B_Q) \subset B_Q$, we conclude that $t^{-1}\Delta t \in B_Q$ for each height one prime $Q$ of $B$. Since $B$ is a Krull ring we have that $t^{-1}\Delta t \in B$ (see [FO, p. 8]).

These facts are to be found in Fossum's book [FO].

**Theorem 1.11.** Let $A = A_0 + A_1 + \cdots$ be a graded Noetherian Krull domain such that $A_0$ is a field. Let $m = A_1 + \cdots$. Then $\text{Cl}(A) \to \text{Cl}(A_m)$ is a bijection [FO, p. 42].

**Theorem 1.12.** Let $A = A_0 + A_1 + \cdots$ be a graded Krull domain such that $A_0$ is a field $k$. Let $k'$ be an extension field of $k$. Suppose $A \otimes_k k' = A'$ is a Krull domain. Then $A'$ is a faithfully flat $A$-module and the induced homomorphism $\text{Cl}(A) \to \text{Cl}(A')$ is an injection [FO, p. 43].

The next theorem generalizes 1.8.

**Theorem 1.13.** Let $\mathcal{S}$ be a finite group of derivations of a Krull domain $B$ of characteristic $p > 0$. Let $A$ be the fixed subring of $\mathcal{S}$. Let $D_1, \ldots, D_r$ be a basis for $\mathcal{S}$ over $\mathbb{Z}/p\mathbb{Z}$. Then the kernel of the homomorphism $\text{Cl}(A) \to \text{Cl}(B)$ is isomorphic to a subgroup of $V_0/V'_0$, where $V_0$ and $V'_0$ are the following subgroups of $L', L = \text{qt}(B)$. $V_0 = \{(t^{-1}D_1 t, \ldots , t^{-1}D_r t) ; \ t \in \text{qt}(B)\}$ and $V'_0 = \{(u^{-1}D_1 u, \ldots , u^{-1}D_r u) ; \ u \in B^*\}$ with $B^*$ the units of $B$ (see [FO, p. 92]).

**Remark 1.14.** The injection in 1.13 is analogous to that of 1.8. If $I$ is a divisorial ideal of $A$ whose class is in the kernel of $\phi : \text{Cl}(A) \to \text{Cl}(B)$, then $B : (B : IB)$ is a principal ideal, say $xB$, for some $x \in B$. We then map $I$ to $(x^{-1}D_1 x, \ldots , x^{-1}D_r x)$ in $V_0/V'_0$.

**2. Properties of $\text{Cl}(F : z^p = G)$.** Throughout this article, unless stated otherwise, $k$ is an algebraically closed field of characteristic $p > 0$. Let $G(x_1, \ldots , x_n) \in k[x_1, \ldots , x_n] \setminus k[x_1^p, \ldots , x_n^p]$ be a polynomial in $n$ variables and $F \subset A_n^{p+1}$ be the hypersurface defined by the equation $z^p = G(x_1, \ldots , x_n)$.

Since $G \not\in k[x_1^p, \ldots , x_n^p]$ if and only if $\partial G/\partial x_i \neq 0$ for some $i = 1, \ldots , n$, we will assume that $\partial G/\partial x_1 \neq 0$.

We will also restrict our attention to hypersurfaces that are normal, or equivalently, to hypersurfaces $F : z^p = G$ for which the greatest common divisor of the $n$-tuple of polynomials $(\partial G/\partial x_1, \ldots , \partial G/\partial x_n)$ in $k[x_1, \ldots , x_n]$ is 1 (see [MA, p. 125]).

Thus we will hereafter assume that $G$ satisfies the condition

\[
(\star) \quad \frac{\partial G}{\partial x_1} \neq 0 \quad \text{and} \quad \gcd \left( \frac{\partial G}{\partial x_1}, \ldots , \frac{\partial G}{\partial x_n} \right) = 1.
\]

**Lemma 2.1.** The coordinate ring of $F$ is isomorphic to $A = k[x_1^p, \ldots , x_n^p, G]$. 

THE HYPERSURFACE $z^p = G(x_1, \ldots, x_n)$

PROOF. The coordinate ring of $F$ is $R = k[x_1, \ldots, x_n, z]/I$, where $I$ is the ideal in $k[x_1, \ldots, x_n, z]$ generated by $z^p - G$. Let $\Phi: k[x_1, \ldots, x_n, z] \to A$ be the mapping that sends each $\alpha \in k$ to $\alpha^p$, each $x_i$ to $x_i^p$, and $z$ to $G$. This is a surjective homomorphism since $k$ is perfect. Thus the kernel of $\Phi$ is a height one prime containing $I$. Since $I$ is height one, $I = \ker \Phi$. Therefore $R$ is isomorphic to $A$ (note that this isomorphism is not a $^p$-isomorphism).

2.2. For each $i = 1, \ldots, n - 1$, let $D_i: k(x_1, \ldots, x_n) \to k(x_1, \ldots, x_n)$ be the $k$-derivation defined by

$$D_i = \frac{\partial G}{\partial x_{i+1}} \cdot \frac{\partial}{\partial x_1} - \frac{\partial G}{\partial x_1} \cdot \frac{\partial}{\partial x_{i+1}}.$$

LEMMA 2.3. $\bigcap_{i=1}^{n-1} D_i^{-1}(0) \cap k[x_1, \ldots, x_n] = A$.

PROOF. We have that

$$k(x_1, \ldots, x_n) \owns D_i^{-1}(0) \owns D_i^{-1}(0) \cap D_i^{-1}(0) \owns \cdots \owns D_i^{-1}(0) \cap \cdots \cap D_{n-1}^{-1}(0) \owns \text{qt}(A),$$

because for each $j = 1, \ldots, n - 1$, $x_{j+1} \in (D_i^{-1}(0) \cap \cdots \cap D_{j-1}^{-1}(0))$ and $D_j(x_{j+1}) \neq 0$. Since $[k(x_1, \ldots, x_n): \text{qt}(A)] = p^n - 1$, it follows that $\text{qt}(A) = \bigcap_{i=1}^{n-1} D_i^{-1}(0)$. Since $A$ is integrally closed, the result follows.

LEMMA 2.4. Let $V = \{(t^{-1}D_i t, \ldots, t^{-1}D_{n-1} t): t \in k(x_1, \ldots, x_n) \text{ and } t^{-1}D_i t \in k[x_1, \ldots, x_n]\}$. Then $\text{Cl}(F)$ injects into $V$.

PROOF. By 1.13 $\text{Cl}(F)$ injects into $V/V'$, where $V' = \{(u^{-1}D_i u, \ldots, u^{-1}D_{n-1} u): u \text{ is a unit in } k[x_1, \ldots, x_n]\}$. Since the units of $k[x_1, \ldots, x_n]$ are exactly the elements of $k$, $V' = 0$.

We can strengthen 2.4 when $n = 2$.

LEMMA 2.5. If $n = 2$, then the injection of 2.4 is also surjective.

PROOF. By 2.1 and 2.3 the coordinate ring of $F$ is isomorphic to $A = k[x_1^p, x_2^p, G]$ and $A = D_1^{-1}(0) \cap k[x_1, x_2]$. Note that $D_1(x_1) = \partial G/\partial x_2$ and $D_1(x_2) = -\partial G/\partial x_1$. Thus the image of $D_1$ restricted to $k[x_1, x_2]$ is not contained in any height one prime of $k[x_1, x_2]$. By 1.8(b), $\text{Cl}(F) \cong V$.

LEMMA 2.6. Let $t \in k[x_1, \ldots, x_n]$ be a logarithmic derivative of $D_i$. Then $\deg t \leq \deg G - 2$.

PROOF. We have that $t = f^{-1}D_i f$ for some $f \in k(x_1, \ldots, x_n)$. There exists $h, g \in k[x_1, \ldots, x_n]$ such that $f = g^{-p}h$. Thus $h^{-1}D_i h = t$. We have that $D_i h = h_x G x_i - h x_{i+1} G x_i$ is of degree at most $\deg h + \deg G - 2$. This shows that $\deg t \leq \deg G - 2$.

PROPOSITION 2.7. $\text{Cl}(F)$ is a $p$-group of type $(p, \ldots, p)$ of order $p^f$, where $f \leq (n - 1)g/(g - 1)/2$, where $g = \deg G$.

PROOF. Let $(t_1, \ldots, t_{n-1}) \in V$. By (2.6), $\deg t_i \leq g - 2$ for each $i$. We will show that there are at most $p^{g/(g-1)}/2$ such $t_i$ for each $i = 1, \ldots, n - 1$. We begin with $t_1$. 

$$D_i = \frac{\partial G}{\partial x_2} \cdot \frac{\partial}{\partial x_1} - \frac{\partial G}{\partial x_1} \cdot \frac{\partial}{\partial x_2}.$$
We have that \( k(x_1, \ldots, x_n) \) is a purely inseparable extension of \( D_1^{-1}(0) \) of degree \( p \).

By 1.9 there exists an \( a \in k[x_1, \ldots, x_n] \cap D_1^{-1}(0) \) such that \( D^p = aD_1 \) and \( t_1 \) is a logarithmic derivative of \( D_1 \) if and only if

\[
D_1^{p-1}(t_1) - at_1 = -t_1^p.
\]

We write \( t_1 = \sum_{r \leq g} \alpha_r x_1^r \) where \( \alpha_r \in k[x_3, \ldots, x_n] \). Substituting this expression for \( t_1 \) into (2.7.1), we obtain on the left side of this equation a polynomial in \( x_1 \) and \( x_2 \) whose coefficients are linear expressions in the \( \alpha_r \) with coefficients in \( k[x_3, \ldots, x_n] \). Comparing the coefficients of \( x_1^p x_2^m \) on both sides of (2.7.1) we see that for each pair of nonnegative integers \( (e, m) \) with \( e + m \leq g - 2 \), \( \alpha_{em} \) must satisfy an equation of the form

\[
L_{em} = \alpha_{em}^p, \quad \text{where } L_{em} \text{ is a linear expression in the } \alpha_r \text{ with coefficients in } k[x_3, \ldots, x_n].
\]

There are a total of \( g(g - 1)/2 \) such equations.

Let \( L \) be an algebraic closure of \( k(x_3, \ldots, x_n) \). The ring \( R = L[\ldots, \alpha_{rs}, \ldots] \) with the relations \( L_{rs} = \alpha_{rs}^p \) is a finite-dimensional \( L \)-vector space spanned by all monomials in the \( \alpha_{rs} \) of degree \( \leq (p - 1)g(g - 1)/2 \). Thus \( R' \) is Artinian and has a finite number of maximal ideals (see [A–M, p. 89]).

Therefore, the \( g(g - 1)/2 \) equations in (2.7.2) have a finite number of solutions in \( L \), which by Bezout's theorem [SH, p. 198] is at most \( p^g(g - 1)/2 \). Hence, the equations in (2.7.2) have at most \( p^g(g - 1)/2 \) solutions in \( k[x_3, \ldots, x_n] \). This implies that there are at most \( p^g(g - 1)/2 \) \( t_1 \)'s.

Similarly, there are at most \( p^g(g - 1)/2 \) possibilities for each \( t_i, i = 2, \ldots, n - 1 \), from which it follows that \( V \) has order \( p^f \) where \( f = (n - 1)g(g - 1)/2 \). Since \( V \subseteq k[x_1, \ldots, x_n] \), each element of \( V \) has \( p \)-torsion. By 2.4, \( \text{Cl}(F) \subseteq \mathbb{V} \). The result follows.

The next result, which I proved in [L2], is entitled "Ganong's formula". Several useful conversations with R. Ganong [G1, G2] led to its discovery. Although Ganong's formula plays a minor role in this article, it is used extensively in [L1 and L2]. For the proof of 2.8 see [L2].

**Theorem 2.8 (Ganong's formula).** Let \( k \) be a field of characteristic \( p > 0 \), \( G \in k[x_1, x_2] \) satisfy condition (*), \( D: k(x_1, x_2) \rightarrow k(x_1, x_2) \) be the \( k \)-derivation \( D = (\partial G/\partial x_2)(\partial/\partial x_1) - (\partial G/\partial x_2)(\partial/\partial x_1) \), and \( a \in k[x_1^p, x_2^p, G] \) be such that \( D^p = aD \) (see 1.9). Then for all \( \alpha \in k(x_1, x_2) \),

\[
D^{p-1}\alpha - a\alpha = -\sum_{i=0}^{p-1} G^i \nabla (G^{p-(i+1)}\alpha),
\]

where \( \nabla = \partial^{2(p-1)}/(\partial x_1^{p-1}\partial x_2^{p-1}) \).

Proposition 2.9 uses Ganong's formula to refine the upper bound of 2.7 in the case \( \gcd(\partial G/\partial x_1, \partial G/\partial x_i) = 1 \) for each \( i = 2, \ldots, n \).
Proposition 2.9. For each $i = 2, \ldots, n$, let $m_i$ be a nonnegative integer such that $2pm_i \leq \deg_{x_i,x_n}(g) \leq 2p(m_i + 1)$. Assume that for each $i$, $\gcd(\partial G/\partial x_i, \partial G/\partial x_i) = 1$. Then the order of $\text{Cl}(F)$ is $p^\ell$, where

$$f \leq g(g - 1)(n - 1)/2 - (p - 1) \sum_{i=1}^{n-1} m_i(2m_i - 1).$$

Proof. For each $i = 1, \ldots, n - 1$, let $D_i$ be as in 2.2. Let $V$ be as in 2.4. If $t$ is a logarithmic derivative of $D_1$, then by 2.6, $\deg_{x_i,x_n}(t) \leq g - 2$. Thus $t = \sum_{r+s+e = g - 2} c_{rs} x_i^r x_n^s$ for some $c_{rs} \in k[x_3, \ldots, x_n]$.

From 1.9 and Ganong’s formula we have that

\begin{equation}
\nabla(G^q t) = \begin{cases}
0, & \text{if } 0 \leq q \leq p - 2, \\
t^p, & \text{if } q = p - 1,
\end{cases}
\end{equation}

where $\nabla = \partial^{2(p-1)}/(\partial x_i^{p-1}\partial x_e^{p-1})$.

Since $\nabla(G^{p-1} t) = t^p$ we obtain for each of the $c_{rs}$ an equation of the form

\begin{equation}
l_{rs} = c_{rs}^p, \text{ where } l_{rs} \text{ is a linear expression in the } c_{je} \text{ with coefficients in } k[x_3, \ldots, x_n].
\end{equation}

If we regroup terms we can write

$$t = \sum_{0 \leq u, v \leq p-1} \alpha_{uv} x_1^u x_2^v$$

with

$$\alpha_{uv} = \sum c_{(u+cp)(v+dp)} x_1^u x_2^v,$$

where this sum is taken over all pairs $(c,d)$ of nonnegative integers such that $0 \leq u + cp + v + dp \leq g - 2$.

Since $\nabla(G^q t)$ is $0$ for $q = 0, \ldots, p - 2$, we obtain the equation

\begin{equation}
L_q: \sum_{0 \leq u, v \leq p-1} \alpha_{uv} \nabla(G^q x_1^u x_2^v) = 0 \quad \text{for } 0 \leq q \leq p - 2.
\end{equation}

These $(p - 1)$ equations (2.9.3) in the $\alpha_{uv}$ with coefficients $\nabla(G^q x_1^u x_2^v)$ are independent over $E = k(x_1^p, x_2^p, x_3, \ldots, x_n)$. For suppose that $\beta_q \in E$, $q = 0, \ldots, p - 2$, such that $\beta_0 L_0 + \cdots + \beta_{p-2} L_{p-2} = 0$.

\begin{equation}
\nabla\left((\beta_0 + \cdots + \beta_{p-2} G^{p-2}) x_1^u x_2^v\right) = 0 \quad \text{for all } 0 \leq u, v \leq p - 1,
\end{equation}

which implies that $\beta_0 + \beta_1 G + \cdots + \beta_{p-2} G^{p-2} = 0$ and, hence, $\beta_0 = \beta_1 = \cdots = \beta_{p-2} = 0$.

We conclude that $(p - 1)$ of the $\alpha_{uv}$'s are $E$-linearly dependent on the remaining ones. Note that each $\alpha_{uv}$ involves at least $m_i(2m_i - 1)$ of the $c_{rs}$'s. Thus we have that among the $c_{rs}$'s there are $(p - 1)m_i(2m_i - 1)$ of them that are determined by the choice of the remaining $g(g - 1)/2 - (p - 1)m_i(2m_i - 1)$ ones. Each of these remaining ones must satisfy an equation of the form (2.9.2). By the argument used in the proof of 2.7 there are $p^{s_1}$ possibilities for the $g(g - 1)/2$-tuple $(c_{00}, c_{10}, c_{01}, \ldots, c_{(g-2)2})$, where $s_1 \leq g(g - 1)/2 - (p - 1)m_i(2m_i - 1)$. Thus there are $p^{s_1}$ possibilities for $t$.

Similarly, $D_i$ has $p^{s_1}$ logarithmic derivatives for $i = 2, \ldots, n - 1$, where

$$s_i \leq g(g - 1)/2 - (p - 1)m_i(2m_i - 1).$$
It follows that $V$ and, hence, $\text{Cl}(F)$ has order $p^s$ where 

$$s \leq (n - 1)g(g - 1)/2 - (p - 1) \sum_{i=1}^{n-1} m_i(2m_i - 1). \quad \text{Q.E.D.}$$

Note that if $\partial G/\partial x_j = 0$ for some $j = 1, \ldots, n - 1$ we can replace $D_j$ with $\partial/\partial x_j$ and still have that $\bigcap_{j \neq i} D_i^{-1}(0) \cap (\partial/\partial x_j)^{-1}(0) = A$.

Since $\partial/\partial x_j$ has only $0$ as a logarithmic derivative, we have the following results.

**Lemma 2.10.** If $G$ is such that $\partial G/\partial x_j = 0$ for $j = 1, \ldots, n$ for some $r > 2$, then $\text{Cl}(F)$ injects into $V' = \{(t^{-1}D_1(t), \ldots, t^{-1}D_{r-1}(t)) : t \in k(x_1, \ldots, x_n) \text{ and } t^{-1}D_i(t) \in k[x_1, \ldots, x_n]\}$.

**Proposition 2.11.** With $G$ as in 2.10 the order of $\text{Cl}(F) = p^s$ where $s < r^{-1}g(g - 1)/2$.

**Proof.** Use 2.10 and the same argument used in the proof of 2.7.

We end this section with some examples.

**Proposition 2.12.** Let $h_1, \ldots, h_r$ be distinct homogeneous irreducible polynomials in $k[x_1, \ldots, x_n]$, the sum of whose degrees is $g$ with $g$ not divisible by $p$. Let $G = h_1 \cdots h_r$ and let $F$ be the hypersurface defined by the equation $z^p = G$. Then $F$ is normal and $\text{Cl}(F)$ has order $p^{r-1}$ generated by the height one primes $GA + h_iA$ in $A = k[x_1^p, \ldots, x_n^p, G]$.

**Proof.** By Euler’s formula, $\sum_{j=1}^{r} x_j(\partial G/\partial x_j) = gG$. If $h$ is a factor of $\partial G/\partial x_j$ for $j = 1, \ldots, n$, then $h$ divides $G$ and must be a multiple factor of $G$. Therefore $\gcd(\partial G/\partial x_1, \ldots, \partial G/\partial x_n) = 1$ and $F$ is normal.

For each pair of positive integers $(j, l)$ with $j \neq l$ and $j, l \leq n$, let $D_{jl}$: $k(x_1, \ldots, x_n) \rightarrow k(x_1, \ldots, x_n)$ be the $k$-derivation defined by

$$D_{jl} = \frac{\partial G}{\partial x_l} \frac{\partial}{\partial x_j} - \frac{\partial G}{\partial x_j} \frac{\partial}{\partial x_l}.$$

Clearly $A \subset (\bigcap D_{jl}^{-1}(0)) \cap k[x_1, \ldots, x_n]$. The reverse inclusion holds by 2.3. Thus $A = (\bigcap D_{jl}^{-1}(0)) \cap k[x_1, \ldots, x_n]$.

Let $\mathcal{H}$ be the $\mathbb{Z}/p\mathbb{Z}$-vector space spanned by the $D_{jl}$. Let $\overrightarrow{D_1}, \ldots, \overrightarrow{D_m}$ be a basis for $\mathcal{H}$, and $W' = \{(f^{-1}\overrightarrow{D_1}(f), \ldots, f^{-1}\overrightarrow{D_m}(f)) : f \in k(x_1, \ldots, x_n) \text{ and } f^{-1}\overrightarrow{D_i}(v) \in k[x_1, \ldots, x_n]\}$ for $i = 1, \ldots, m$. By 1.13, $\text{Cl}(F)$ injects into $W'$.

We begin by showing that

(2.12.1) \quad \text{if } (V_1, \ldots, V_m) \in W', \text{ then there exists a homogeneous polynomial } t \in k[x_1, \ldots, x_n] \text{ such that } t^{-1}\overrightarrow{D_i}(t) = v_i \text{ for } i = 1, \ldots, m.

Temporarily fix an $i = 1, \ldots, m$. Suppose that $v = u^{-1}\overrightarrow{D_i}(u) \in k[x_1, \ldots, x_n]$ where $u \in k(x_1, \ldots, x_n)$. Multiplying $u$ by an element in $k[x_1^p, \ldots, x_n^p]$ we can assume that $u \in k[x_1, \ldots, x_n]$.

Let $v_1$ and $u_1$ ($v_2$ and $u_2$) be the lowest (highest) degree forms of $v$ and $u$, respectively.
We have that \( \deg(u_1) + g - 2 \leq \deg(D_i(u)) \leq \deg(u_2) + g - 2 \). If we compare the forms of lowest and highest degree of both sides of the equality \( D_i(u) = uv \), we see that \( \deg(v_2) + \deg(u_2) \leq \deg(u_2) + g - 2 \) and \( \deg(v_1) + \deg(u_1) \geq \deg(u_1) + g - 2 \). This implies that \( g - 2 \leq \deg(v_1) \leq \deg(v_2) \leq g - 2 \) (i.e. \( v \) is homogeneous of degree \( g - 2 \)). Thus it must be that \( \deg(D_i(u)) = \deg(u_2) + g - 2 \) and hence \( D_i(u_2') = u_2v \).

It follows that if \( (v_1, \ldots, v_n) \in W \) with \( u^{-1}D_i(u) = v_i \) for each \( i \), then we can assume that \( u \) is a polynomial and the highest degree form of \( u \), say \( \tilde{u} \), is such that \( u^{-1}D_i(\tilde{u}) = v_i \) for each \( i \). This verifies (2.12.1).

Furthermore, if \( \tilde{u} = u_1^{r_1} \cdots u_s^{r_s} \) is a prime factorization of \( \tilde{u} \), then \( e_1u_1^{-1}D_i(u_1) + \cdots + e_su_s^{-1}D_i(u_s) = v_i \) and each of the elements \( e_1u_1^{-1}D_i(u), \ldots, e_su_s^{-1}D_i(u) \in k[x_1, \ldots, x_n] \), for each \( i \). Thus

\[
W \text{ is generated by all elements of the form}
\]

\[
\left( \tilde{u}^{-1}D_i(\tilde{u}), \ldots, \tilde{u}^{-1}D_m(\tilde{u}) \right) \text{ with } \tilde{u} \text{ an irreducible homogeneous polynomial.}
\]

Let \( y \in k[x_1, \ldots, x_n] \) be irreducible and homogeneous such that \( y \) divides \( D_i(y) \) for each \( i \). Since the \( D_i \) generate \( \mathfrak{m} \), \( y \) divides \( D_j(y) \) for each pair \( (j, l), j \neq l \leq n \).

Therefore, for each \( j = 1, \ldots, n, y \) divides

\[
\sum_{i \neq j} x_iD_j(y) = \sum_{i \neq j} x_i \left( \frac{\partial G}{\partial x_i} \frac{\partial y}{\partial x_j} - \frac{\partial G}{\partial x_j} \frac{\partial y}{\partial x_i} \right)
\]

\[
= \sum_{i = 1}^n x_i \left( \frac{\partial G}{\partial x_i} \frac{\partial y}{\partial x_j} - \frac{\partial G}{\partial x_j} \frac{\partial y}{\partial x_i} \right)
\]

\[
= gG \frac{\partial y}{\partial x_j} - \deg(y) \frac{\partial G}{\partial x_j} y
\]

by Euler's formula. This implies that \( y \) divides \( G(\partial y/\partial x_j) \) for each \( j = 1, \ldots, n \). Since \( y \) is irreducible there exists \( j_0 \) such that \( \partial y/\partial x_j \neq 0 \). Then \( y \) does not divide \( \partial y/\partial x_{j_0} \) and hence \( y \) divides \( G \). This fact, together with (2.12.2), implies that

\[
W \text{ is generated by the elements}
\]

\[
w_q = \left( h_q^{-1}D_i(h_q), \ldots, h_q^{-1}D_m(h_q) \right), \quad q = 1, \ldots, r.
\]

Note that \( w_1 + \cdots + w_r = (G^{-1}D_i(G), \ldots, G^{-1}D_m(G)) = (0, \ldots, 0) \). Thus \( (w_1, \ldots, w_{r-1}) \) generate \( W \) over \( \mathbf{Z}/p\mathbf{Z} \).

If \( d_1, \ldots, d_{r-1} \) are positive integers such that \( d_1w_1 + \cdots + d_{r-1}w_{r-1} = 0 \), then \( D_i(h_1^{d_1} \cdots h_r^{d_{r-1}}) = 0 \) for each \( i \) and thus \( h = h_1^{d_1} \cdots h_{r-1}^{d_{r-1}} \in A \). We then have that

\[
k(x_1^{p}, \ldots, x_n^{p}) \subset k(x_1^{p}, \ldots, x_n^{p}, h) \subset qt(A).
\]

If \( k(x_1^{p}, \ldots, x_n^{p}, h) = qt(A) \), then there exists \( \alpha_0, \ldots, \alpha_p \in k[x_1^{p}, \ldots, x_n^{p}] \) such that \( \alpha_0G = \alpha_1 + \alpha_2h + \cdots + \alpha_ph^{p-1} \). Since \( G \) and \( h \) are homogeneous, we may assume that \( \alpha_0, \ldots, \alpha_p \) are also. Since \( \deg(\alpha_ih^{i-1}) \) is congruent to \( (i - 1)\deg h \) modulo \( p \) and \( \deg(\alpha_iG) = g \pmod{p} \), we have that only one of \( \alpha_1, \ldots, \alpha_p \neq 0 \). Thus \( \alpha_0G = \alpha_ih^{i-1} \) for some \( i = 1, \ldots, p \). But this is clearly impossible.
Thus $k(x_1^p, \ldots, x_n^p, h) = k(x_1^p, \ldots, x_n^p)$ and $d_i = \cdots = d_{r-1} = 0 \pmod{p}$. It follows that $\{w_1, \ldots, w_{r-1}\}$ forms a basis for $W$ over $\mathbb{Z}/p\mathbb{Z}$ and the order of $W$ is $p^{r-1}$.

Finally we note that the nonprincipal height one primes $Q_i = GA + h_i^pA$ in $A$ map to the elements $w_i$ for $i = 1, \ldots, r$, under the homomorphism described in 1.14. Therefore $\text{Cl}(F) \approx W$ and has order $p^{r-1}$ generated by $Q_1, \ldots, Q_{r-1}$.

Remark 2.13. Proposition 2.12 is not valid when $p$ divides $g$. For we will see in a moment that the hypersurface $z^p = x_1^p \cdots x_n^p + x_0$ has nontrivial class group although the polynomial $x_1^p \cdots x_n^p + x_0$ is irreducible in $k[x_0, x_1, \ldots, x_p]$.

We can use 2.12 to attack some special cases when $p$ divides $g$.

Corollary 2.14. Let $h_1, h_2, \ldots, h_r$ be distinct homogeneous irreducible polynomials in $k[x_1, \ldots, x_n]$. Let $G = x_0h_1 \cdots h_r$. Then $F: z^p = G \subset \mathbb{A}^{n+2}$ is normal and the order of $\text{Cl}(F)$ is $p^r$.

Proof. Let $g = \deg G$. If $p$ does not divide $g$ then the result follows by 2.12.

Suppose then that $g = pm$. Then $\gcd(\partial G/\partial x_1, \ldots, \partial G/\partial x_n) = x_0$. Thus $\gcd(\partial G/\partial x_0, \ldots, \partial G/\partial x_n) = 1$ and $F$ is normal.

Let $R = k[x_0, \ldots, x_n, z]$, $z^p = G$. $R$ is the coordinate ring of $F$.

We have that $R[1/x_0] \cong R_1$ where $R_1 = k[x_0', \ldots, x_n', z', 1/x_0']$. $(z')^p = h_1' \cdots h_r'$, where $h_j' = h_j(x_1', \ldots, x_n')$ for $j = 1, \ldots, r$.

The map $R_1 \to R$ is given by $x_0' \to x_0$, $z' \to z/x_0^m$, $x_i' \to x_i/x_0$ for $i = 1, \ldots, n$.

By 1.4, $\text{Cl}(R_1) \cong \text{Cl}(R_2)$, where $R_2 = k[x_0', \ldots, x_n', z']$, $(z')^p = h_1' \cdots h_r'$. By 1.6, $\text{Cl}(R_2) \cong \text{Cl}(R_3)$ where $R_3 = k[x_1', \ldots, x_n', z']$, $(z')^p = h_1' \cdots h_r'$. By 2.12, the order of $\text{Cl}(R_3)$ is $p^{r-1}$. Hence $\text{Cl}(R[1/x_0])$ has order $p^{r-1}$.

Again by 1.4 we have an exact sequence

$$0 \to \ker \phi \to \text{Cl}(R) \xrightarrow{\phi} \text{Cl}(R[1/x]) \to 0,$$

where $\ker \phi$ is generated by those height one primes in $R$ that contain $x_0$. Such a prime ideal would have to contain $z$ also and hence the ideal $x_0R + zR$ which is easily seen to be a nonprincipal height one prime.

Thus $\ker \phi \cong \mathbb{Z}/p\mathbb{Z}$, from which it follows that $\text{Cl}(R)$ has order $p^r$.

Corollary 2.15. The divisor class group of the hypersurface $F \subset \mathbb{A}^{n+2}$ defined by the equation $z^p = x_1 \cdots x_n$ is a direct sum of $np - 1$ copies of $\mathbb{Z}/p\mathbb{Z}$.

Remark 2.16. The hypersurface in 2.13 is isomorphic to the hypersurface $z^p = x_1 \cdots x_n$ which has nontrivial class group by 2.15.

3. The hypersurface $z^{p^m} = G$. In this section we study the divisor class group of hypersurfaces of the form $z^{p^m} = G(x_1, \ldots, x_n)$. Studies of this type, using higher order derivations, have been conducted by K. Baba [BA]. We describe another sort of inductive procedure of obtaining information about $\text{Cl}(F: z^{p^m} = G)$.

As always, we let $k$ be an algebraically closed field of characteristic $p > 0$ and $G(x_1, \ldots, x_n) \in k[x_1, \ldots, x_n]$ satisfy condition ($\ast$). For each positive integer $m$, let $F_m \subset \mathbb{A}_k^{n+1}$ be the hypersurface (necessarily normal) defined by the equation $z^{p^m} = G(x_1, \ldots, x_n)$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Lemma 3.1. For each $m$, the coordinate ring of $F_m$ is isomorphic to $A_m = k[x_1^{p^m}, \ldots, x_n^{p^m}, G]$.

Proof. Similar to the proof of 2.1.

For each positive integer $m$, let $B_m = k[x_1^{p^m+1}, \ldots, x_n^{p^m+1}, G^p]$. $B_m$ is clearly isomorphic to $A_m$ and $B_m \subset A_{m+1} \subset A_m$ with $A_m$ integral over $B_m$. Also $[\text{qt}(A_m) : \text{qt}(A_{m+1})] = p^{m-1}$ and $[\text{qt}(A_m) : \text{qt}(B_m)] = p$.

By 1.3 there exist group homomorphisms $\theta_m : \text{Cl}(B_m) \to \text{Cl}(A_{m+1})$ and $\phi_m : \text{Cl}(A_{m+1}) \to \text{Cl}(A_m)$. We use derivations to study $\theta_m$ and $\theta_m$. We start with $\theta_m$.

Let $E_m$ be the restriction of the derivation $G_x(\partial/\partial x_1)$ on $k(x_1, \ldots, x_n)$ to $A_{m+1}$.

Lemma 3.2. $E_m$ maps $A_{m+1}$ into $A_{m+1}$ and has kernel $B_m$.

Proof. Let $\alpha \in A_{m+1}$. Then $\alpha = \sum_{i=0}^{p-1} \beta_i G^i$ for unique $\beta_i \in B_m$. We have that $E_m(\alpha) = \sum_{i=1}^{p-1} i \beta_i G^{i-1}$.

Thus $E_m(\alpha) \in A_{m+1}$ and $E_m(\alpha) = 0$ if and only if $\beta_1 = \cdots = \beta_{p-1} = 0$, that is, if and only if $\alpha \in B_m$.

Proposition 3.3. For each positive integer $m$, $\text{Cl}(F_m)$ injects into $\text{Cl}(F_{m+1})$.

Proof. With $E_m : A_{m+1} \to A_{m+1}$ as above, let $\mathcal{E}_{m+1} \subset A_{m+1}$ be the group of logarithmic derivatives of $E_m$. Let $\mathcal{E}_{m+1}$ be the group of logarithmic derivatives of units of $A_{m+1}$.

Given $\alpha \in A_{m+1}$, $\text{deg}(E_m(\alpha)) < \text{deg} \alpha - \text{deg} G$. It follows that if $\alpha^{-1} E_m(\alpha) \in A_{m+1}$, then $E_m(\alpha) = 0$. Therefore $\mathcal{E}_{m+1} = \mathcal{E}_{m+1}$. By 1.8, $\ker(\theta_m) = 0$. To gain some understanding of $\phi_m : \text{Cl}(A_{m+1}) \to \text{Cl}(A_m)$ we define derivations $D_{mi} : \text{qt}(A_m) \to \text{qt}(A_m)$ for each $i = 1, \ldots, n - 1$.

Given $\alpha \in \text{qt}(A_m)$, there exists unique $\alpha_j \in k[x_1, \ldots, x_n]$ such that

$$\alpha = \sum_{j=0}^{p^m-1} \alpha_j G^j.$$

3.4. Define

$$D_{mi}(\alpha) = \sum_{j=0}^{p^m-1} \left(D_i(\alpha_j)\right) \alpha_j G^j$$

where

$$D_i = \frac{\partial G}{\partial x_{i+1}} \frac{\partial}{\partial x_i} - \frac{\partial G}{\partial x_i} \frac{\partial}{\partial x_{i+1}} \quad \text{for} \quad i = 1, \ldots, n - 1.$$

Of course we must show that $D_{mi}$ is indeed a derivation.

Lemma 3.5. The mappings $D_{mi}$, as defined in 3.4, are derivations.

Proof. Clearly $D_{mi}$ is additive. We show that the multiplicative property holds, that is, $D_{mi}(u v) = u D_{mi}(v) + v D_{mi}(u)$ for all $u, v \in \text{qt}(A_m)$.

Let

$$u = \sum_{j=0}^{p^m-1} \alpha_j G^j \quad \text{and} \quad v = \sum_{j=0}^{p^m-1} \beta_j G^j \in \text{qt}(A_m),$$

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
where the $\alpha_i, \beta_j \in k(x_1, \ldots, x_n)$. We argue by induction on the number of nonzero coefficients appearing in $u$ plus the number of nonzero coefficients appearing in $v$.

Suppose this sum is 2. Then $u = \alpha_p^s G^r$ and $v = \beta_p^s G^s$ for some $u, v \in k(x_1, \ldots, x_n)$, $r, s$ nonnegative integers.

Then
\[
D_{m_1}(uv) = D_{m_1}\left( (\alpha\beta)^{p^m} G^{r+s} \right) = (D_1(\alpha\beta))^{p^m} G^{r+s} = (\alpha D_1\beta + \beta D_1\alpha)^{p^m} G^{r+s} \\
= \alpha_p^s G^r D_{m_1}(\beta_p^s G^s) + \beta_p^s G^s D_{m_1}(\alpha_p^s G^r) = uD_{m_1}(v) + vD_{m_1}(u).
\]

Now assume that the total number of nonzero coefficients appearing in $u$ and $v$ is greater than 2. Let $0 < j_0 < p^m$ be the highest power of $G$ with nonzero coefficient in $v$. Let this coefficient be $\gamma_p^m$. Then
\[
D_{m_1}(uv) = D_{m_1}\left( u(v - \gamma_p^m G^{j_0}) \right) + D_{m_1}\left( u\gamma_p^m G^{j_0} \right),
\]

which, by the induction hypothesis,
\[
= uD_{m_1}(v - \gamma_p^m G^{j_0}) + (v - \gamma_p^m G^{j_0})D_{m_1}(u) + uD_{m_1}(\gamma_p^m G^{j_0}) + \gamma_p^m G^{j_0}D_{m_1}(u) \\
= uD_{m_1}(v) + vD_{m_1}(u).
\]

**Lemma 3.6.** Let $D_{m_1}$: $q_1(A_m) \to q_1(A_m)$ be as in 3.4.

(i) Then $A_{m+1} = \ker D_{m_1} \cap \cdots \cap \ker D_{m(n-1)} \cap A_m$.

(ii) Let
\[
V_m = \left\{ \left( t_{-1}D_{m_1}t, \ldots, t_{-1}D_{m(n-1)}t \right) : t \in q_1(A_m) \text{ and } t_{-1}D_{m_1}t \in A_m \right\}.
\]
Then $\ker \phi_n$ injects into $V_m$.

(iii) Let $a_i \in D_{i-1}(0) \cap k[x_1, \ldots, x_n]$ be such that $D_{m_i}p = a_iD_i$. Then $D_{m_i}p = a_i^{p^m}D_{m_1}$, $i = 1, \ldots, n - 1$.

**Proof.** (i) Similar to 2.3.

(ii) Similar to 2.4.

(iii) By 1.9, $\exists a_i \in D_{i-1}(0) \cap k[x_1, \ldots, x_n]$ such that $D_{i}p = a_iD_i$. Then
\[
D_{m_i}(x_1^{p^m}) = (D_{i}p(x_1))^{p^m} = (a_iD_i(x_1))^{p^m} = a_i^{p^m}D_{m_1}(x_1).
\]

**Proposition 3.7.** For each $j = 1, 2, \ldots, n - 1$, let
\[
t_j = \alpha_0^{p^m} + \alpha_1^{p^m} G + \cdots + \alpha_{k(n-1)}^{p^m} G^{p^m} \in A_m.
\]

(a) If $(t_1, \ldots, t_{n-1}) \in V_m$, then $\alpha_{j_0} = 0$ if and only if $\alpha_{j_r} = 0$ for $r = 0, \ldots, p^m - 1$.

(b) If $\gcd(G_{x_1}, G_{x_j}) = 1$ in $k[x_1, \ldots, x_n]$ for each $j = 1, \ldots, n - 1$, then $(t_1, \ldots, t_{n-1}) \in V_m$ if and only if
\[
(1) \ \nabla_j(G^{s}\alpha_{j_r}) = 0 \text{ for } 0 \leq r \leq p^m - 1 \text{ and } r \not\equiv 0 \pmod{p}, \text{ and} \\
(2) \ \nabla_j(G^{s}\alpha_{j(x)}(G^{s}\alpha_{j(x)}) = \alpha_j(x)^s(\alpha_{j(x)}^{p^m} - 1) \text{ for } s = 0, 1, \ldots, p^m - 1 - 1, \text{ where } \nabla_j = \frac{\partial^{|x|}}{\partial x_j^{|x|}} \text{ and } |x| = \frac{|x_j|}{p^{|x|-1}}. \\
\]

**Proof.** (b) Let $j = 1, \ldots, n - 1$. By 1.9(b) and 3.6(iii) we have
\[
D_{m_j}^{-1}(t_j) - a_j^p t_j = -t_j^p, \ \text{ where } D_{m_j} = a_jD_j.
\]
This is equivalent to
\[
\sum_{r=0}^{p^m-1} \left( D_{j}^{p^{-1}} \alpha_j - a_j \alpha_j \right)^{p^m} G^r = - \sum_{s=0}^{p^m-1} \alpha_s^{p^{m-1}} G^{sp}.
\]

Comparing coefficients of $G^r$ in (3.7.2) we obtain
\[
(t_1, \ldots, t_{n-1}) \in V_m \quad \text{if and only if for each } j = 1, \ldots, n-1,
\]

(1) \quad $D_{j}^{p^{-1}} \alpha_j - a_j \alpha_j = 0$ \quad for $r \neq 0 \pmod{p}$, \quad $0 \leq r \leq p^m - 1$,

and
\[
\sum_{s=0}^{p^{(m-1)-1}} \left( D_{j}^{p^{-1}} \alpha_{js(p)} - a_j \alpha_{js(p)} \right)^{p^m} G^{sp} = - \sum_{s=0}^{p^m-1} \alpha_s^{p^{m-1}} G^{sp}.
\]

Taking $p$th roots and comparing coefficients of $G^s$ in (3.7.3)(2), (2) becomes
\[
\left( D_{j}^{p^{-1}} \alpha_{js(p)} - a_j \alpha_{js(p)} \right) \left( D_{j}^{p^{-1}} \alpha_{js(p)} - a_j \alpha_{js(p)} \right)^{p^{-1}} = - \sum_{i=0}^{p^{-1}} \alpha_{js+i(p^{m-1})}^{p^{(m-1)}} G^{ip^{m-1}}
\]
for $0 \leq s \leq p^{(m-1)} - 1$,

which is equivalent to
\[
D_{j}^{p^{-1}} \alpha_{js(p)} - a_j \alpha_{js(p)} = - \sum_{i=0}^{p^{-1}} \alpha_{js+i(p^{m-1})}^{p} G^{i} \quad \text{for } 0 \leq s \leq p^{(m-1)} - 1.
\]

If $\gcd(G_{x_j}, G_{y_j}) = 1$, then we can apply Ganong’s formula (2.8) to the left side of (3.7.3)(1) and to the left side of (3.7.5), and comparing coefficients of $G^i$ we obtain (b).

**Proof of (a).** To prove (a), we proceed by reverse induction on $v(r)$, where $v(r)$ = the highest power of $p$ that divides $r$.

Note that if $v(r) \geq m$ then $\alpha_j = \alpha_0$. Assume then that $v(r) = d < m$. We can write $r = s + 0 \cdot p^{m-1}$ for unique $s = 0, \ldots, p^{(m-1)} - 1, c = 0, \ldots, p - 1$. Since $v(r) = d$ we have that $s = p^d e$ for some $e = 0, \ldots, p - 1$.

By the induction hypothesis $\alpha_{js(p)} = 0$. By (3.7.5), we see that
\[
\sum_{i=0}^{p^{-1}} \alpha_{js+i(p^{m-1})}^{p} G^{i} = 0,
\]
which shows that $\alpha_j = 0$.

**Theorem 3.8.** For each $m$, $\ker \varphi_m$ is a $p$-group of type $(p, \ldots, p)$ of order $p^f$ where $f \leq (n-1)g(g-1)/2$ with $g = \deg G$.

**Proof.** For each $j = 1, \ldots, n-1$ let $t_j = \alpha_{j0}^{p^m} + \cdots + \alpha_{j(p^{m-1})}^{p^m} G^{p^m-1} \in A_m$. Assume that $(t_1, \ldots, t_{n-1}) \in V_m$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Proof. By (3.7.5)

\[
D_j^{p-1} \alpha_j - a_j \alpha_j = - \sum_{i=0}^{p-1} \alpha_i \alpha_j^{p^i-1} G^i, \quad \text{where } D_j^p = a_j D_j.
\]

Let \( E_j: k(x_1, \ldots, x_n) \to k(x_1, \ldots, x_n) \) be the derivation defined by \( E_j = G^{-1}_x(\partial / \partial x_j) \).
Then \( E_j(A_1) \subset A_1 \) and if \( h \in A_1 \), then \( \deg(E_j(h)) = \deg h - g \). From (3.8.1) we obtain

\[
(3.8.2) \quad \alpha_j^0 = -E_j^{p-1} G^{p-1}(D_j^{p-1} \alpha_j - a_j \alpha_j^0) \quad \text{and} \quad p \deg(\alpha_j^0) \leq \deg D_j^{p-1} \alpha_j - a_j \alpha_j^0.
\]

For all \( h \in k[x_1, \ldots, x_n] \), \( \deg(D_j h) \leq \deg(h) + g - 2 \). Thus

\[
\deg(a_j) \leq (p-1)(g-2)
\]

and

\[
(3.8.3) \quad \deg D_j^{p-1} \alpha_j - a_j \alpha_j^0 \leq \deg(\alpha_j^0) + (p-1)(g-2).
\]

(3.8.2) and (3.8.3) together imply that

\[
(3.8.4) \quad \deg(\alpha_j^0) \leq g-2.
\]

Claim 3.8.5. Let \( L \) be an algebraic closure of \( k(x_2, \ldots, x_{j-1}, x_{j+1}, \ldots, x_n) \). If \( \alpha_1, \ldots, \alpha_r \in L[x_1, x_j] \) satisfy (3.8.2) and are \( \mathbb{Z}/p\mathbb{Z} \)-independent, then \( \alpha_1, \ldots, \alpha_r \) are \( L \)-independent also.

Proof of claim. The case \( r = 1 \) is obvious. We proceed by induction on \( r \).
Suppose that \( e_1, \ldots, e_r \in L \) are such that \( e_i \alpha_1 + \cdots + e_r \alpha_r = 0 \). From (3.8.2) we obtain

\[
e_1 \alpha_1^0 + \cdots + e_r \alpha_r^0 = 0 \quad \text{Thus} \quad (e_1^{p-1} e_2^p - e_2^p \alpha_1^0 + \cdots + (e_1^{p-1} e_r^p - e_r^p) \alpha_r^0 = 0.
\]

By the induction hypothesis we have that \( e_i^{p-1} e_i^p = e_i^p = 0 \) for \( i = 2, \ldots, r \). If \( e_1 \neq 0 \), then \( (e_1 / e_1)^p = e_i / e_i^p \), that is \( e_i / e_1 \in \mathbb{Z}/p\mathbb{Z} \) for each \( i \). But this contradicts the fact that the \( \alpha_i \) are \( \mathbb{Z}/p\mathbb{Z} \)-independent since \( \alpha_1 + (e_2 / e_1) \alpha_2 + \cdots + (e_r / e_1) \alpha_r = 0 \). Therefore \( e_1 \) must equal 0. Using the induction hypothesis again, we have that \( e_2 = \cdots = e_r = 0 \) also. \( \Box \)

Note that the \( L \)-vector space of all polynomials in \( L[x_1, x_j] \) of degree \( \leq g - 2 \) has dimension \( g(g-1)/2 \).

From (3.8.4) and (3.8.5) it follows that the \( \mathbb{Z}/p\mathbb{Z} \)-vector space of all \( \alpha_j^0 \) satisfying (3.8.2) is of dimension at most \( g(g-1)/2 \).

From 3.7(a) we conclude that \( V_m \), and hence ker \( \phi_m \), has order \( p^f \) where \( f \leq ng(g-1)/2 \). Q.E.D.

Theorem 3.9. For each \( m \), \( \text{Cl}(F_m) \) is a finite \( p \)-group of type \( (p^{i_1}, \ldots, p^{i_s}) \) where each \( i_j \leq m \). The order of \( \text{Cl}(F_m) \) \( \leq p^{m(n-1)g(s-k)/2} \), where \( g = \deg G \).

Proof (by induction on \( m \)). For \( m = 1 \), use 2.7. For each \( m > 1 \), we have the exact sequence

\[
(3.9.1) \quad 0 \to \ker \phi_m \to \text{Cl}(F_{m+1}) \xrightarrow{\phi_m} \text{Cl}(F_m) \to 0.
\]

Now just use induction and 3.8.
Remark 3.10. Using the mappings $\theta_m$ and $\phi_m$ we obtain an inductive procedure for studying $\text{Cl}(F_m)$. For we have the following diagram for each $m$:

$$
\begin{align*}
\text{Cl}(B_m) & \xrightarrow{\theta_m} \text{Cl}(A_{m+1}) \xrightarrow{\phi_m} \text{Cl}(A_m) \\
D_{m,j} : A & \rightarrow A_m \\
\ker \phi_m & \xrightarrow{V_m} \{ t^{-1}D_{m_1}, \ldots, t^{-1}D_{m_{n-1}}, t \in \text{qt}(A_m) \\
& \& t^{-1}D_{m_j}t \in A_m, j = 1, 2, \ldots, n-1 \}\.
\end{align*}
$$

We finish this section with two examples.

Proposition 3.11. Let $h_1, \ldots, h_r$ be distinct homogeneous irreducible polynomials in $k[x_1, \ldots, x_n]$, the sum of whose degree is g not divisible by p. For each $m$, let $F_m \subseteq A_{n+1}$ be the hypersurface defined by $z^m = G$ where $G = h_1 \cdots h_r$. Then $F_m$ is normal and $\text{Cl}(F_m)$ is a direct sum of $r-1$ copies of $\mathbb{Z}/p^m\mathbb{Z}$, generated by the height one primes $GA_m + h_1^p A_m$ in $A_m$, $i = 1, \ldots, r-1$.

Proof. As in the proof of 2.12, we have that $\gcd(\partial G/\partial x_1, \ldots, \partial G/\partial x_n) = 1$. Thus $F_m$ is normal for each $m$.

Also, as in 2.12, we let $D_{st} = (\partial G/\partial x_s)(\partial G/\partial x_t) - (\partial G/\partial x_t)(\partial G/\partial x_s)$ for each pair $(s, t)$ with $s \neq t$ and $1 \leq s, t \leq n - 1$. Let $\mathcal{C}$ be the $\mathbb{Z}/p\mathbb{Z}$-vector space spanned by the $D_{st}$. Let $D_1, \ldots, D_{\lambda}$ be a basis for $\mathcal{C}$, and $W = \{(f^{-1}\overline{D_1}f), \ldots, f^{-1}\overline{D_{\lambda}}f) : f \in k[x_1, \ldots, x_n] \text{ and } f^{-1}D_{st}f \in k[x_1, \ldots, x_n] \text{ for } i = 1, \ldots, \lambda\}$.

For each $m > 0$, let $D_m : \text{qt}(A_m) \rightarrow \text{qt}(A_m)$ be defined by

$$
D_m(\alpha_0^m + \cdots + \alpha_{p-1}^m G^{p^{-1}}) = (\overline{D_1} \alpha_0)^m + \cdots + (\overline{D_{\lambda}} \alpha_{p-1})^m G^m.
$$

$W_m = \{(f^{-1}\overline{D_1}f, \ldots, f^{-1}\overline{D_{\lambda}}f) : f \in \text{qt}(A_m) \text{ and } f^{-1}D_{m_1}f \in A_m \text{ for } i = 1, \ldots, \lambda\}$.

Then as in 3.6(i), $\bigcap_{m=1}^{\lambda} D_m \cap A_m = A_{m+1}$. Since the $D_m$ are $\mathbb{Z}/p\mathbb{Z}$ independent, so are the $D_{m_i}$. By 2.4, $\phi_m$ injects into $W_m$. We will now demonstrate that $W_m$ has order $p^{r-1}$ and $\ker \phi_m$ surjects onto $W_m$.

Let $v \in A_m$ be such that $v = f^{-1}\overline{D_m}f$ for some $f \in \text{qt}(A_m)$ and some $i$. Clearly, we can assume that $f \in A_m$. Let $f_1$ and $v_1$ be the lowest degree forms and $f_2$ and $v_2$ the highest degree forms of $f$ and $v$, respectively. Then $f_1, v_1, f_2, v_2$ all belong to $A_m$ and either $\overline{D_m}(f_2) = 0$ or $\deg \overline{D_m}(f_2) = \deg f_2 + (g - 2)p^m$. Similarly, for $f_1$.

Thus

$$
\deg v_2 + \deg f_2 \leq \deg f_2 + (g - 2)p^m
$$

and

$$
\deg v_1 + \deg f_1 \geq \deg f_1 + (g - 2)p^m.
$$

It follows that $(g - 2)p^m \leq \deg v_1 \leq \deg v_2 \leq (g - 2)p^m$. Thus $v$ is homogeneous of degree $(g - 2)p^m$. Therefore $v$ can only be of the form $v = u^p$ for some $u \in k[x_1, \ldots, x_n]$ of degree $g - 2$. By 1.9(b), $v$ is a logarithmic derivative of $\overline{D_m}$ if and only if $(\overline{D_m})^{p^{-1}}(v) - \overline{\alpha_m} v = -v^p$ where $\overline{\alpha_m}$ is the element of $A_m$ such that
\( \tilde{D}_i^p = \tilde{a}_i D_i^p \). From 3.6(iii), \( \tilde{a}_i = \tilde{a}_i^p \) where \( \tilde{a}_i \in k[x_1, \ldots, x_n] \) is such that \( \tilde{D}_i^p = \tilde{a}_i D_i \). We then have that

\[
\begin{align*}
\text{if } v \in A_m \text{ is a logarithmic derivative of } \tilde{D}_i, \
\text{and only if } v = u^p \text{ where } u \in k[x_1, \ldots, x_n] \text{ and} \\
\tilde{D}_i^p - \tilde{a}_i u = -u^p \text{ (i.e. } u \text{ is a logarithmic} \\
\text{derivative of } \tilde{D}_i). 
\end{align*}
\]

Thus

\[
(3.11.1) \quad (v_1, \ldots, v_{n-1}) \in W_{m} \text{ if and only if there exists} \\
u_j \in k[x_1, \ldots, x_n] \text{ such that } (u_1, \ldots, u_{n-1}) \in W
\]

where \( v_j = u_j^p \), where \( W \) is as in 2.4.

From this fact it follows that the mapping \((u_1, \ldots, u_{n-1}) \to (u_1^p, \ldots, u_{n-1}^p)\) from \( W \) to \( W_{m} \) is an isomorphism.

In 2.12 we showed that \( W \) has order \( p^{n-1} \), hence \( \ker \phi_m \) has order \( p^{n-1} \). We have that the height one primes \( \mathfrak{Q}_i = GA_m + h_i^{p} A_m \) have ramification index 1 over their contractions \( Q_i = GA_{m+1} + h_i^{p} A_{m+1} \) in \( A_{m+1} \), and \( Q_i \) has ramification index \( p \) over their contractions \( \mathfrak{Q}_i' = G^{p} B_m + h_i^{p^m} B_m \) in \( B_m \), \( i = 1, \ldots, r - 1 \).

Using induction we have that the primes \( \mathfrak{Q}_i \) generate \( \text{Cl}(A_m) \) and are of order \( p^m \), hence the same holds true of the primes \( \mathfrak{Q}_i' \) in \( B_m \).

Since \( \theta_m : \text{Cl}(B_m) \to \text{Cl}(A_{m+1}) \) is injective by 3.3 we see that the elements \( p^m Q_i \) are a \( \mathbb{L}/p\mathbb{Z} \)-basis for \( \ker \phi_m \). Since the ramification indexes \( e(\mathfrak{Q}_i; Q_i) = 1 \) we have that \( \phi_m \) is surjective. The theorem follows.

**PROPOSITION 3.12.** Let \( h_1, \ldots, h_r \) be distinct irreducible homogeneous polynomials in \( k[x_1, \ldots, x_n] \). Let \( G = x_0 h_1 \cdots h_r \) and \( F_m \subset A^{n+2} \) be the hypersurface defined by \( z^p^m = G \). Then \( \text{Cl}(F_m) \) is a direct sum of \( r \) copies of \( \mathbb{L}/p^m \mathbb{Z} \), generated by the nonprincipal height one primes \( Q_i = h_i^{p} A_m + GA_m, \) \( i = 1, \ldots, r \).

**PROOF.** Let \( h = h_1 \cdots h_r \), and \( R = k[x_0, x_1, \ldots, x_n, z], \ z^p^m = G \), which is the coordinate ring of \( F_m \). By 1.4 we have an exact sequence

\[
(3.12.1) \quad 0 \to H \to \text{Cl}(R) \to \text{Cl}(R[1/h]) \to 0,
\]

where \( H \) is the subgroup of \( \text{Cl}(R) \) generated by those nonprincipal height one primes in \( R \) that contain \( h \).

We have that

\[
R \left[ \frac{1}{h} \right] \simeq k \left[ \frac{z^p^m}{h}, x_0, x_1, \ldots, x_n, z, \frac{1}{h} \right] = k \left[ x_1, \ldots, x_n, z, \frac{1}{h} \right].
\]

By 1.4, \( k[x_0, \ldots, x_n, z, 1/h] \) is factorial. Therefore, \( \text{Cl}(R[1/h]) = 0 \). From (3.12.1) we see that \( H \) is isomorphic to \( \text{Cl}(R) \). It follows that \( \text{Cl}(A_m) \) is generated by those height one primes in \( A_m \) that contain \( h^p^m \). Let \( Q \subset A_m \) be one such prime. Then there is a unique principal height one prime \( f k[x_0, \ldots, x_n] \) in \( k[x_0, \ldots, x_n] \) that lies over \( Q \). \( f \) must divide \( h \), thus \( f \) must be a \( k \)-multiple of \( h_i \) for some \( i = 1, \ldots, r \). Thus \( Q = Q_i \) for some \( i = 1, \ldots, r \), and \( \text{Cl}(A_m) \) is generated by the \( Q_i \).
THE HYPERSURFACE $z^p = G(x_1, x_2)$

By 3.9, $p^m Q_i = 0$ in $\text{Cl}(A_m)$ for each $i$. We will now show that the $Q_i$ are $\mathbb{Z}/p^m \mathbb{Z}$-independent. The $m = 1$ case is covered by 2.14. We proceed by induction on $m$.

We will be done if we show that the elements $p^{m-1} Q_i$ are independent over $\mathbb{Z}/p \mathbb{Z}$. Let $Q_i = Q_i \cap B_{m-1} = h_i^{p^{m-1}} B_{m-1} + G^p B_{m-1}$. The ramification index of $Q_i$ over $Q_i$ is $p$ for $i = 1, \ldots, r$. By induction $\{p^{m-2} Q_i, \ldots, p^{r} Q_i\}$ are $\mathbb{Z}/p \mathbb{Z}$-independent in $\text{Cl}(B_m)$. Since $\theta_{m-1}(p^{m-2} Q_i) = p^{m-1} Q_i$ for $i = 1, \ldots, r$ and $\theta_{m-1}$ is an injection, the elements $p^{m-1} Q_i$ are independent over $\mathbb{Z}/p \mathbb{Z}$.

Remark 3.13. Note that if $\emptyset$ is the origin of the surface $F_m$ in 3.12 or 3.13, then by 1.11 the divisor class group of the local ring of $F_m$ at $\emptyset$, $\text{Cl}((F_m)_{\emptyset})$, and $\text{Cl}(F_m)$ are isomorphic.

4. $\text{Cl}(F: z^p = G(x_1, x_2))$ for a generic $G$. We begin this section by focusing our attention on the case $n = p = 2$. We assume that $k$ is an algebraically closed field of characteristic 2. Let $G(x_1, x_2) \in k[x_1, x_2]$ satisfy condition $(*), D$ be the derivation on $k(x_1, x_2)$ defined by $D = (\partial G/\partial x_2)(\partial/\partial x_1) - (\partial G/\partial x_1)(\partial/\partial x_2), \mathcal{E} \subset k[x_1, x_2]$ be the group of logarithmic derivatives of $D$ (i.e. $\mathcal{E} = \{f^{-1} Df | f \in k(x, y) \text{ and } f^{-1} Df \in k[x_1, x_2]\}$), and $F \in A_2^k$ be defined by the equation $z^2 = G(x_1, x_2)$.

By 2.5, $\text{Cl}(F) \cong \mathcal{E}$.

Observe that $D(G_{x_1}) = G_{x_2} G_{x_1 x_1} - G_{x_1} G_{x_1 x_2} = G_{x_1} G_{x_1 x_2}$. Hence $G_{x_1 x_2} = G_{x_1}^{-1} D(G_{x_1}) \in \mathcal{E}$. Therefore

(4.1) If $G_{x_1 x_2} \neq 0$, then $\text{Cl}(F) \neq 0$. Thus for a generic choice of $G$, the surface $F$ has nontrivial divisor class group.

Note that by 3.3 we have that

(4.2) If $G_{x_1 x_2} \neq 0$, then the divisor class group of the surface $F_n: z^{2^n} = G(x_1, x_2)$ is not trivial.

Remark 4.3. By (4.1), $G_{x_1 x_2} \neq 0$ implies that $\text{Cl}(F: z^2 = G) \neq 0$. We then should be able to produce a nonprincipal height one prime in $A = k[x^2, y^2, G]$, which is isomorphic to the coordinate ring of $F$ (2.1). This is accomplished with the aid of the next lemma.

Lemma 4.4. Let $f \in k[x_1, x_2]$ be such that $f^{-1} Df \in k[x_1, x_2]$. Suppose that $f = g'h$, where $g \in k[x_1, x_2]$ is irreducible, $h \in k[x_1, x_2]$ is such that $\gcd(h, g) = 1$, and $r$ is a positive integer not divisible by $p$ (the characteristic of $k$). Then $g^{-1} Dg \in k[x_1, x_2]$.

Proof. Let $t = f^{-1} Df$. Then $ft = Df = D(g'h) = rg'^{-1}(Dg)h + g'^{-1} Dh$. Thus $g$ divides $rhDg$, which implies that $g$ divides $Dg$.

We continue the search for the nonprincipal height one prime. Let $G_{x_1} = G_{x_1}^{r_1} \cdots G_{x_1}^{r_n}$ be a factorization of $G_{x_1}$ into irreducible factors in $k[x_1, x_2]$. Since $G_{x_1 x_2} \neq 0$, one of the $r_i$ is not divisible by 2, say $r_1$. By 4.4, $G_{x_1}^{-1} D G_{x_1} \in k[x_1, x_2]$.

Let $I = G_{x_1} k[x_1, x_2] \cap A$. $I$ is clearly a height one prime. To show that $I$ is not principal, first note that $D(G_{x_1} G_{x_2}^{x_2}) = 0$. By 2.3, $G_{x_1} G_{x_2} \in A$. $r_1 = 2s_1 + 1$ for some nonnegative integer $s_1$. Then

$$G_{x_1}^{2s_1} G_{x_1} G_{x_2} = G_{x_1}^{2s_1} \cdots G_{x_1}^{r_n} G_{x_2} \in k[x_1, x_2] \cap \text{quat}(A) = A.$$
We conclude that $G_1^{-2x}G_2G_3$ is an element of $I$ by value 1 in the valuation on $k(x_1, x_2)$ induced by $G_1 k[x_1, x_2]$. It follows that the ramification index of $G_1 k[x_1, x_2]$ over $I$ is 1. Thus $\phi_0: Cl(A) \rightarrow \mathbb{L}$ maps $I$ to $G_1^{-1}DG_1$. Since $\phi$ is well defined, $I$ must be nonprincipal.

**Remark 4.5.** Since $Cl(F: z^2 = G(x_1, x_2)) \neq 0$ for a generic $G$ (namely, if $G_{x_1 x_2} \neq 0$), we naturally arrive at two questions.

(4.5.1) What is $Cl(F: z^2 = G(x_1, x_2))$ for a generic choice of the coefficients of $G$?

(4.5.2) Is it also the case that for $p > 2$ the surface $F''z^p = G(x_1, x_2)$ has nontrivial class group?

One approach towards answering these questions is to bound the degree of $G$ and study the corresponding system of equations one obtains via the differential equation of 1.9(b). More explicitly, for a positive integer $n$, we let $G_n(x_1, x_2)$ be a polynomial in the variables $x_1$ and $x_2$ with undetermined coefficients of degree $n$. Let $D$ be the derivation on $k(x_1, x_2)$ defined by $D = (\partial G_n/\partial x_2)(\partial /\partial x_1) - (\partial G_n/\partial x_1)(\partial /\partial x_2)$. We then try to determine if there is a generic way of choosing the coefficients of $G$ so that the differential equation of 1.9(b) has a fixed number of solutions in $k(x_1, x_2)$.

This approach I used in [L2], demonstrating that for a generic choice of $G_n$ the divisor class group of the surface $F: z^p = G_n$ is 0 in the following cases: (i) $p = 3$, $n = 4$, (ii) $p = 3$, $n = 6$, and (iii) $p > 2$, $n = 3$.

Also in [L2], I showed that for a generic $G_n$, $Cl(F: z^2 = G_n)$ is $\mathbb{Z}/2\mathbb{Z}$ if $n = 5$ or 6, and is a direct sum of four copies of $\mathbb{Z}/2\mathbb{Z}$ if $n = 4$ (see [L2] for more details).

In this paper we attempt to shed some light on the local version of these questions. We ask

(4.5.3) Does there exist a group $\mathfrak{M}$ and a generic way of choosing $G(x_1, x_2)$ such that for each singular point $Q \in F: z^p = G$, $Cl(F_Q) \simeq \mathfrak{M}$ (by $F_Q$ we mean the local ring of $F$ at $Q$)?

**Proposition 4.6.** The divisor class group of the ring $R_n = k[x_1^n, x_2^n, x_1 x_2]$ is isomorphic to $\mathbb{Z}/p^n\mathbb{Z}$.

We give two very different and interesting proofs of 4.6. The first of these, which makes use of a proposition of N. Hallier [HA1], involves logarithmic derivatives. The second, a geometric argument, uses results of J. Lipman [LI2, pp. 224–240] and P. Blass [BL1, pp. 107–121].

The following proposition, whose proof we provide, is due to N. Hallier [HA1, p. 2].

**Proposition 4.6.1.** Let $A$ be a local Krull domain with maximal ideal $m$ such that $A$ and $A/m$ are of equal characteristic $p > 0$. Let $D: A \rightarrow A$ be a derivation such that the ideal $I = D(A) \cdot A$ in $A$ is contained in $m$. Let $a \in A$ be such that $D^p = aD$. If $a$ is a unit in $A$ then each $t \in m$ that is the logarithmic derivative of an element $f \in qt(A)$ is the logarithmic derivative of a unit $u$ in $A$.

**Proof.** Replacing $f$ by an element of $A^pf$ we can assume that $f \in A$. If $f$ is a unit in $A$, we are done. If $f \in m$, then we have by induction that $(af)^{-1}D^pf \in m$ for all positive integers $n$. Let $u = -1 + (af)^{-1}D^{p^{-1}}f$. Then $D(u^{-1})/u^{-1} = f^{-1}Df = t$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
**Proposition 4.6.2.** Let $A, m, D, I$ and $a$ be as in (4.6.1). Let $U$ be the multiplicative group of units in $A$. Let $\mathcal{E} = \{f^{-1}Df \mid f \in \text{qt}(A) \text{ and } f^{-1}Df \in A \}$ be the group of logarithmic derivatives in $A$ and $\mathcal{E}' = \{u^{-1}Du \mid u \in U \}$. Then either $\mathcal{E} = \mathcal{E}'$ or $\mathcal{E}/\mathcal{E}' \cong \mathbb{Z}/p\mathbb{Z}$.

**Proof.** Let $\theta: \mathcal{E} \to A/m$ be the additive group homomorphism mapping each $t \in \mathcal{E}$ to its image $i$ in $A/m$. By (4.6.1), $\ker \theta = \mathcal{E}'$. Thus $\theta$ induces an injection $\tilde{\theta}: \mathcal{E}/\mathcal{E}' \to A/m$.

By 1.9, an element $t \in \mathcal{E} \Rightarrow D^{p-1}(t) - at = -t^p$. Thus if $t \in \mathcal{E}$ we have that $at = i^p$. Since $\widetilde{a} \neq 0$, the polynomial $x^p - \widetilde{a}x$ has $p$ distinct roots in an algebraic closure of $A/m$. It follows that the order of $\tilde{\theta}(\mathcal{E}/\mathcal{E}')$ is at most $p$. Since $\mathcal{E}/\mathcal{E}'$ is a $p$-group the result follows.

**First Proof of (4.6).** Let $D: k[[x_1, x_2]] \to k[[x_1, x_2]]$ be the derivation defined by $D = x_1(\partial/\partial x_1) - x_2(\partial/\partial x_2)$. Then, as in 3.4, we can use $D$ to define derivations $D_n: R_n \to R_n$ with $\ker D_n = R_{n+1}$ and $D_n^p = D_n$ for each $n$. If we let $\phi_n: \text{Cl}(R_{n+1}) \to \text{Cl}(R_n)$ be the homomorphism of 1.3, then by 1.8, $\ker(\phi_n) \cong \mathcal{E}_n/\mathcal{E}_n'$, where $\mathcal{E}_n = \{f^{-1}D_n(f) \mid f \in \text{qt}(R_n) \text{ and } f^{-1}D_n f \in R_n \}$ and $\mathcal{E}_n' = \{u^{-1}D_n(u) \mid u \text{ is a unit in } R_n \}$.

By (4.6.2), the order of $\ker(\phi_n) \leq p^n$. Then by induction we see that the order of $\text{Cl}(R_n) \leq p^n$. By 1.7 and 3.12 we have the desired result.

Since the second proof of (4.6) uses techniques not developed in this paper, we give only an outline. For more details see the above-mentioned articles.

**Second Proof of (4.6).** Let $m$ be the maximal ideal of $R_n$. There exists a desingularization $f: X \to \text{Spec}(R_n)$ such that the closed fibre has distinct components $E_1, E_2, \ldots, E_{p^n-1}$ with intersection as follows:

\[
E_i \cdot E_j = 1 \quad \text{if } |i - j| = 1,
E_i \cdot E_j = 0 \quad \text{if } 0 \neq |i - j|,
E_i^2 = -2
\]

(see [BL1, pp. 107–121] for the case $n = 1, p > 2$).

The intersection matrix $((E_i, E_j))$ is given by the $(p^n - 1)$ by $(p^n - 1)$ square matrix

\[
\begin{bmatrix}
-2 & 1 & & & \\
1 & -2 & & & \\
& & \ddots & & \\
& & & -2 & 1 \\
& & & 1 & -2
\end{bmatrix}
\]

with determinant $p^n$.

From Proposition 17.1 of [LI2] and the discussion on p. 225 of [LI2] we have that the order of $\text{Cl}(R_n)$ is equal to $(d_1 \cdots d_{p^n-1})^{-1}\det((E_i, E_j))$, where $d_i$ = degree of $E_i$.

Applying 1.7 and 3.12 we conclude that

\[
\frac{1}{d_1 \cdots d_{p^n-1}} \det((E_i, E_j)) = p^n \quad \text{and} \quad \text{Cl}(R_n) \cong \mathbb{Z}/p^n\mathbb{Z}.
\]
Remark. 4.7. Suppose that $G(x_1, x_2)$, in addition to satisfying condition $(*)$, is such that the polynomials $G_{x_1}, G_{x_2}$, and $G_{x_1}G_{x_2} - G_{x_1x_2}$ have no points in common (a generic assumption on $G$).

P. Blass [BL1] has shown that under this condition all singularities on $F^{$: $z^p = G(x_1, x_2)$ are rational with local equation of the form $z^p = xy +$ (higher degree terms).

Hereafter we will refer to this additional condition on $G(x_1, x_2)$ as condition (B).

Proposition 4.8. Let $G \in k[x_1, x_2]$ satisfy condition (B). Let $Q$ be a singular point of the surface $F \subset \mathbb{A}^2_k$ defined by the equation $z^p = G$. Then $\text{Cl}(F)$ injects into $\mathbb{Z}/p\mathbb{Z}$.

Proof. After a linear change of coordinates we may assume that $Q$ is the origin $(x_1 = x_2 = z = 0)$ of $F$ and $G$ has the form $G = x_1x_2 +$ higher degree terms (see Remark 4.7).

Let $A = k[x_1^p, x_2^p, G]$ and let $m$ be the maximal ideal of $A$ corresponding to $Q$.

By 1.7 there exists an injection $\text{Cl}(A_m) \rightarrow \text{Cl}(\hat{A})$, where $\hat{A}$ is the completion of $A_m$ at $m$.

We have that $\hat{A} = k[x_1^p, x_2^p, G]$. In $k[x_1, x_2] G$ factors into a product $G = uv$ where $u$ and $v$ are of the form $u = x_1 +$ higher degree terms, $v = x_2 +$ higher degree terms. Clearly $k[x, y] = k[u, v]$. Thus $\hat{A} = k[u^p, v^p, uv]$. By 4.6, $\text{Cl}(A) \approx \mathbb{Z}/p\mathbb{Z}$.

Thus question (4.5.3), posed at the beginning of this section, can be answered when $p = 2$.

Corollary 4.9. Let $k$ be an algebraically closed field of characteristic 2, $G \in k[x_1, x_2]$ satisfy condition (B), and $Q$ be a singular point of the surface $F: z^2 = G(x_1, x_2)$. Then $\text{Cl}(F_Q) \cong \mathbb{Z}/2\mathbb{Z}$.

Proof. Note that $G_{x_1x_2} \neq 0$ since $G$ satisfies condition (B) and $F$ has a singularity. Then as in Remark 4.3, there exists an irreducible polynomial $G_1 \in k[x_1, x_2]$ such that $G_1$ divides $G_{x_i}$ and such that the height one prime $G/k[x_1, x_2] \cap A = I$ in $A = k[x_1^p, x_2^p, G]$ is nonprincipal. Since $Q$ is a singular point, $I$ is contained in the maximal ideal of $A$ corresponding to $Q$. Therefore the mapping $\text{Cl}(F) \rightarrow \text{Cl}(F_Q)$ of 1.4 is not the zero mapping. By 4.8, $\text{Cl}(F_Q) \subset \mathbb{Z}/2\mathbb{Z}$, from which it follows that $\text{Cl}(F_Q) \approx \mathbb{Z}/2\mathbb{Z}$.

Remark (4.10). For the case $p > 2$, 4.8 tells us that if $Q$ is a singularity of the surface $F: z^p = G(x_1, x_2)$, with $G$ satisfying condition (B), then $\text{Cl}(F_Q) = 0$ or $\mathbb{Z}/p\mathbb{Z}$. The question as to which, if either, of these groups is $\text{Cl}(F_Q)$ for a generic $G$ is an open one.

5. $\text{Cl}(A)$ for $A$ between $k[x_1^p, \ldots, x_n^p]$ and $k[x_1, \ldots, x_n]$. We come to the last topic to be discussed in this article. We show that if $A$ is an integrally closed domain such that $k[x_1^p, \ldots, x_n^p] \subset A \subset k[x_1, \ldots, x_n]$, where $k$ is a field of characteristic $p > 0$, then $\text{Cl}(A)$ is a finite $p$-group of type $(p^{i_1}, \ldots, p^{i_r})$ with each $i_j < mn$. We will use the following fact found in [JA, p. 185, Exercise 3].
**Lemma 5.1.** Let $P$ and $L$ be fields such that $P$ is purely inseparable of exponent 1 over $L$ and $[P : L] = p^m < \infty$. Then there exists a derivation $D$ of $P/L$ such that $D^{-1}(0) = L$.

**Lemma 5.2.** Let $k$ be field of characteristic $p > 0$, $B$ an integrally closed finitely-generated $k$-subalgebra of $k[x_1, \ldots, x_n]$ and $D$ a $q(B)/k$ derivation such that $[q(B) : D^{-1}(0)] = p$. Let $A = D^{-1}(0) \cap B$. Then the homomorphism $\phi: Cl(A) \to Cl(B)$ of 1.3 has kernel of finite order and type $(p, \ldots, p)$.

**Proof.** There exists $f_1, \ldots, f_r \in k[x_1, \ldots, x_n]$ such that $B = k[f_1, \ldots, f_r]$. We can insure by multiplying $D$ by an appropriate element of $B$ that $D(B) \subset B$. Let $\mathcal{E} \subset B$ be the group of logarithmic derivatives of $D$. That is, $\mathcal{E} = \{ t'xDt | t \in q(B) \text{ and } t'xDt \in B \}$. By 1.8(a) there exists an injection $\ker\phi \subseteq \mathcal{E}$. Let

$$d = \max \{ \deg(Df_i) - \deg f_i \}.$$ 

If $h \in \mathcal{E}$, then there exists $t \in q(B)$ such that $t^{-1}Dt = h$. We can assume $t \in B$, for we can multiply $t$ by a $p$th power of an element in $B$ to arrange this.

We have that $\deg(Dt) \leq \deg t + d$, which implies that $\deg h \leq d$. Thus $\mathcal{E}$ is contained in the $k$-vector space of polynomials of degree $\leq d$, which has dimension $< \infty$.

(5.2.1) If $h_1, \ldots, h_s$ are in $\mathcal{E}$ and are independent over $\mathbb{Z}/p\mathbb{Z}$, then $h_1, \ldots, h_s$ are $\bar{k}$-independent ($\bar{k}$ an algebraic closure of $k$).

We prove (5.2.1) by induction on $s$. The case $s = 1$ is obvious.

Suppose that $\alpha_i h_1 + \cdots + \alpha_s h_s = 0$ with $\alpha_i \in k$ and $\{h_1, \ldots, h_s\}$ independent over $\mathbb{Z}/p\mathbb{Z}$.

By 1.9, there exists $a \in A$ such that $D^p = aD$. We also have that

$$(5.2.2) \quad \sum_{i=1}^{s} \alpha_i h_i^p - \sum_{i=1}^{s} (D^p - aI)\alpha_i h = - (D^p - aI) \sum_{i=1}^{s} \alpha_i h = 0,$$

where $I$ is the identity map. Thus $\sum_{i=1}^{s} (\alpha_i)^{1/p} h_i = 0$.

Suppose that $\alpha_s \neq 0$. Then

$$(5.2.3) \quad \sum_{i=1}^{s-1} \left[ (\alpha_s)^{1/p} \alpha_i - \alpha_s (\alpha_i)^{1/p} \right] h_i = (\alpha_s)^{1/p} \sum_{i=1}^{s} \alpha_i h_i - \alpha_s \sum_{i=1}^{s} (\alpha_i)^{1/p} h_i = 0.$$ 

By induction, $(\alpha_s)^{1/p} \alpha_i - \alpha_s (\alpha_i)^{1/p} = 0$ for $1 \leq i \leq s - 1$. This implies that $(\alpha_i/\alpha_s)^p = \alpha_i/\alpha_s$ and $\alpha_i/\alpha_s \in \mathbb{Z}/p\mathbb{Z}$ for each $i$.

Hence $\sum \alpha_i h_i = 0$ implies that $\sum (\alpha_i/\alpha_s) h_i = 0$, which contradicts the fact that the $h_i$ are $\mathbb{Z}/p\mathbb{Z}$ independent. We conclude that $\alpha_s$, and hence all $\alpha_i$, equals 0.

Since $\mathcal{E} \subset B$, each element of $\mathcal{E}$ has $p$-torsion. By (5.2.1) $\mathcal{E}$ has no more than a finite number of independent elements.

**Proposition 5.3.** Let $k$ be a field of characteristic $p > 0$ and let $A$ be an integrally closed domain such that $k[x_1^p, \ldots, x_n^p] \subset A \subset k[x_1, \ldots, x_n]$. Then $Cl(A)$ is a finite $p$-group of type $(p^i_1, \ldots, p^i_r)$ with each $i_j < mn - 1$.

**Proof.** $k(x_1, \ldots, x_n)$ is a purely inseparable extension of $q(B)$ of degree $p^t$ where $s < mn$. There exist fields $k(x_1, \ldots, x_n) = L_0 \supset L_1 \supset \cdots \supset L_s = q(B)$, with $L_i/L_{i+1}$ a purely inseparable extension of degree $p$. 
For each \( i = 0, \ldots, s \), let \( A_i = k[x_1, \ldots, x_n] \cap L_i \). Then \( A_s = A \) and each \( A_i \) is a finite \( k[x_1^{p}, \ldots, x_n^{p^s}] \)-module. Thus each \( A_i \) is Noetherian and a Krull domain (\( A_i \) is an intersection of Krull domains). Hence each \( A_i \) is integrally closed (see [SI, p. 5]).

By 5.1, there exist derivations \( D_i : L_i \to L_i \) such that \( D_i^{-1}(0) = L_{i+1} \).

By 5.2 the homomorphism \( \phi_i : \text{Cl}(A_{i+1}) \to \text{Cl}(A_i) \) has kernel of finite order and of type \((p, \ldots, p)\). Inductively we see that each \( A_i \) has class group of finite order and of type \((p_1, \ldots, p_s)\) where each \( r_j \leq i \).
