TENSOR PRODUCTS AND GROTHENDIECK TYPE INEQUALITIES OF OPERATORS IN $L_p$-SPACES

BERND CARL AND ANDREAS DEFANT

Abstract. Several results in the theory of $(p, q)$-summing operators are improved by a unified but elementary tensor product concept.

Introduction

Since the pioneering work of Grothendieck in Linear Functional Analysis there is an extensive literature dealing with operators in $L_p$-spaces. Still the most important result in this direction is Grothendieck's integral characterization [9] of operators from $l_1$ into $l_2$: There is a universal constant $K_G > 0$ such that for every operator $S: l_1 \to l_2$ there is a probability measure $\nu$ on the unit ball $B_{l_2}$ of $l_2$ (endowed with its weak* topology) for which

$$\|Sx\| \leq K_G \|S\| \int |\langle x, a \rangle| d\nu(a)$$

holds for all $x \in l_1$. For information on estimates of the constant $K_G$ we refer to [20]. This result which is now called Grothendieck's Theorem—Grothendieck himself called it "the fundamental theorem of the metric theory of tensor products"—motivated the following statement of this paper: there is an absolute constant $k > 0$ such that for every operator $S: l_1 \to l_v$ ($1 \leq v \leq \infty$) and every probability measure $\mu$ on $B_{l_v'}$ ($v'$ the conjugate index $v/(v-1)$) there is a probability measure $\nu$ on $B_{l_2}$ with

$$\left( \int |\langle Sx, a \rangle|^s d\mu(a) \right)^{1/s} \leq k \|S\| \int |\langle x, a \rangle| d\nu(a) ;$$

for all $x \in l_1$, where $2 \leq s \leq \infty$ and $\frac{1}{s} = \frac{1}{2} - \frac{1}{v}$. Operators satisfying such integral inequalities were defined and intensively studied by Maurey [16] who proved several deep equivalent characterizations. One of them combined with our result states that every operator $S: l_1 \to l_v$ ($1 \leq v \leq \infty$) maps an unconditional summable sequence $(x_i)$ in $l_1$ into a sequence $(Sx_i)$ which is the product of an absolutely $s'$-summable scalar sequence $(\alpha_i)$ and a weakly $s$-summable sequence $(y_i)$ in $l_v$, here again $2 \leq s \leq \infty$ and $\frac{1}{s} = \frac{1}{2} - \frac{1}{v}$. Within the theory of absolutely summing operators which was initiated by Pietsch [22], our result has the following formulation: If $2 \leq s \leq \infty$ and $\frac{1}{s} = \frac{1}{2} - \frac{1}{v}$,
then the composition of an arbitrary operator \( S : l_1 \to l_0 \) with an absolutely 
\( s \)-summing operator \( T : l_0 \to E \) is already absolutely summing.

The proof is based on two powerful concepts, which at a first glance have 
nothing in common with each other, and also Kwapien's important extension 
[12] of Grothendieck's Theorem, namely: If \( 1 \leq v \leq \infty \) and \( \frac{1}{r} = 1 - \frac{1}{2} - \frac{1}{v} \),
then every operator \( S : l_1 \to l_0 \) is absolutely \((r, 1)\)-summing, i.e., it transforms 
every unconditional summable sequence of \( l_1 \) into an absolutely \( r \)-summable 
sequence of \( l_0 \). Our first step is to use Kwapien's result and the concept of 
Weyl numbers (treated in König [11] and Pietsch [23]) to obtain some weaker 
estimates concerning our statement. The next step is to improve these estimates 
by a general procedure based on a certain kind of tensor multiplicativity of some 
operator norms with respect to tensor products of \( L_p \)-spaces.

Along similar lines we study identity operators \( I \) from \( l_u \) into \( l_v \) (\( 1 \leq 
u \leq v \leq \infty \)). In particular, we prove for \( I : l_u \leftarrow l_2 \) the following integral 
characterization: there is a constant \( k(u) > 0 \) (depending just on \( u \)) such that 
for every probability measure \( \mu \) on \( B_{l_2} \) there is a probability measure \( \nu \) on 
\( B_{l_u} \) for which

\[
\left( \int |(x, a)|^{u'} \, d\mu(a) \right)^{1/u'} \leq k(u) \int |(x, a)|^{u} \, d\nu(a)
\]

holds for all \( x \in l_u \). This is a generalization of a well-known characterization of 
absolutely \((r, 1)\)-summing identity operators \( I : l_u \leftarrow l_2 \) due to Bennett [2] and 
(independently) the first author [4], which itself extends old results of Hardy 
and Littlewood [10] on continuous bilinear forms on \( l_p \times l_q \) (\( 1 \leq p, q \leq \infty \)).

Moreover, we give new integral descriptions of Schatten-von Neumann oper-
ators of type \( L_r \).

The paper is divided into two main parts; in the first part we recall the basic 
definitions and results of Maurey's theory of \((s, p)\)-mixing operators and de-
develop our basic tools; in the second part we prove the above-mentioned integral 
characterizations of operators acting between \( L_p \)-spaces.

1. \((s, p)\)-MIXING OPERATORS, WEURL NUMBERS AND 
TENSOR MULTIPLICATIVITY

Let us start with some preliminaries. We shall use standard notations and 
notions from Banach space theory, as presented in [15]. For the general theory 
of Banach operator ideals which was founded by Pietsch, we refer the reader to 
the monograph [22].

If \( E \) is a Banach space (over the scalar field \( \mathbb{K} = \mathbb{R} \) or \( \mathbb{C} \)), then \( B_E \) is its 
(closed) unit ball and \( E' \) its dual. By \( W(B_{E'}) \) we denote the set of all (regular 
Borel) probability measures on the weak*-compact space \( B_{E'} \). A family \( (x_i) \) in \( E \) is called absolutely \( p \)-summable (\( 0 < p \leq \infty \)) if

\[
l_p(x_i) := l_p(x_i; E) := \left( \sum_i \|x_i\|_p^p \right)^{1/p} < \infty,
\]

and weakly \( p \)-summable if

\[
w_p(x_i) := w_p(x_i; E) := \sup \left\{ \left( \sum_i |(x_i, a)|^p \right)^{1/p} \mid a \in B_{E'} \right\} < \infty
\]
(with the obvious modifications for \( p = \infty \)). By an \( L_p \)-space \( (1 \leq p \leq \infty) \) we mean a Banach space \( L_p(\Omega, \Sigma, \mu) \) for some measure space \((\Omega, \Sigma, \mu)\). The class of all \( L_p \)-spaces includes \( l_p \) and all spaces \( l_p^n := \mathbb{K}^n \) equipped with the norm \( l_p(\cdot) \).

As usual \( \mathcal{L}(E, F) \) denotes the Banach space of all (bounded and linear) operators \( S \) from \( E \) to \( F \) endowed with the operator norm

\[
\|S\| := \sup\{\|Sx\| \mid x \in B_E\}.
\]

An operator \( T \in \mathcal{L}(E, F) \) is called absolutely \((r, p)\)-summing \((0 < p \leq r \leq \infty)\) if there is a constant \( \rho \geq 0 \) such that \( l_r(Tx_i) \leq \rho w_p(x_i) \), for all finite sets of elements \( x_1, \ldots, x_n \in E \). In this case the infimum over all possible \( \rho \geq 0 \) is denoted by \( \pi_{r, p}(T) \). Then \([\mathcal{P}_r, p, \pi_{r, p}]\) is a \([\min\{p, 1\}]\)-normed Banach ideal of operators.

By a result of Kwapien

\[
[\mathcal{P}_{r_1, p_1}, \pi_{r_1, p_1}] \subseteq [\mathcal{P}_{r_2, p_2}, \pi_{r_2, p_2}],
\]

if \( r_1 \leq r_2, \ p_1 \leq p_2 \) and \( 1/r_1 - 1/p_1 = 1/r_2 - 1/p_2 \). If \( r = p \) one gets the ideal \([\mathcal{P}_p, \pi_p]\) of all absolutely \( p \)-summing operators. The Grothendieck-Pietsch domination theorem states that \( S \in \mathcal{P}_p^p(E, F) \) \((0 < p \leq \infty)\) if and only if there is a \( \rho \geq 0 \) and a \( \nu \in W(B_{F'}) \) for which

\[
\|Sx\| \leq \rho \left( \int |\langle x, a \rangle|^p d\nu(a) \right)^{1/p}
\]

holds for each \( x \in E \). In this case again \( \pi_p(T) = \min \rho \). Moreover, we mention Pietsch's composition formula for absolutely summing operators:

\[
[\mathcal{P}_s, \mathcal{P}_r, \pi_s \cdot \pi_r] \subseteq [\mathcal{P}_p, \pi_p], \quad \frac{1}{s} + \frac{1}{r} = \frac{1}{p} \leq 1.
\]

Let us finally recall the definition of a \( p \)-nuclear operator. An operator \( T \in \mathcal{L}(E, F) \) is said to be \( p \)-nuclear \((1 \leq p \leq \infty)\) if it admits a representation

\[
T = \sum_{i=1}^{\infty} a_i \otimes y_i,
\]

with \( l_p(a_i; E')w_p(y_i; F) < \infty \). Put \( N_p(T) := \inf l_p(a_i)w_p(y_i) \). Then the class \( \mathcal{N}_p \) of all \( p \)-nuclear operators together with \( N_p \) defines a Banach ideal of operators and

\[
[\mathcal{N}_p, N_p] \subseteq [\mathcal{P}_p, \pi_p], \quad 1 \leq p \leq \infty.
\]

### 1.1. A brief résumé of Maurey's theory of \((s, p)\)-mixing operators.

Operators of the following type for the first time were investigated in Maurey's fundamental thesis [16]:

An operator \( S \in \mathcal{L}(E, F) \) is called \((s, p)\)-mixing \((0 < p \leq s < \infty)\) if there is a constant \( \rho \geq 0 \) such that for every probability measure \( \mu \in W(B_{F'}) \) there is a probability measure \( \nu \in W(B_{E'}) \) with

\[
\left( \int |\langle Sx, a \rangle|^s d\mu(a) \right)^{1/s} \leq \rho \left( \int |\langle x, a \rangle|^p d\nu(a) \right)^{1/p},
\]

for all \( x \in E \).

With \( \mu_{s, p}(S) := \inf \rho = \min \rho \) the class \( \mathcal{M}_{s, p} \) of all \((s, p)\)-mixing operators forms a \([\min\{p, 1\}]\)-normed Banach ideal. Obviously \([\mathcal{M}_p, \mu_p, p] = \]
and because of the domination theorem it makes sense to define $[\mathcal{L}_p, \mu, \pi_p] := [\mathcal{R}_p, \pi_p]$ for $0 < p \leq \infty$.

We now recall some basic results about $(s, p)$-mixing operators most of which can be found at least implicitly in Maurey’s thesis [16] (see also [17]). In a condensed form the theory of these operators appeared in Pietsch [22] and Puhl [24]. Most of the following results will be used throughout this paper.

The phrase “$(s, p)$-mixing” refers to the following deep characterization by Maurey [16]: an operator $S \in \mathcal{L}(E, F)$ is $(s, p)$-mixing if and only if it maps every weakly $p$-summable scalar sequence $(x_i)$ in $E$ into a sequence which can be written as a product $(\alpha_i, y_i)$ of an absolutely $r$-summable scalar sequence $(\alpha_i)$ and a weakly $s$-summable sequence $(y_i)$ in $F$, where $1 + \frac{1}{s} + \frac{1}{r} = \frac{1}{p}$.

The following very useful composition formula is an immediate consequence of the definition: for $0 < p \leq s \leq t \leq \infty$

$$[\mathcal{M}_t, s \cdot \mathcal{M}_s, p, \mu_{t, s}, \mu_{s, p}] \subseteq [\mathcal{M}_t, p, \mu_t, p]$$

Furthermore, we need a “local” version of the definition of an $(s, p)$-mixing operator: By the Grothendieck-Pietsch domination theorem it is easy to see that an operator $S \in \mathcal{L}(E, F)$ is $(s, p)$-mixing $(0 < p \leq s < \infty)$ if and only if for every $\mu \in W(B_{F'})$ the mapping

$$E \rightarrow F \rightarrow L_\infty(B_{F'}, \mu)$$

$$x \mapsto (a \mapsto (Sx, a))$$

is absolutely $p$-summing, i.e., there is $\rho > 0$ such that for all $x_1, \ldots, x_n \in E$

$$\left( \sum_{i=1}^{n} \left( \int |(Sx_i, a)|^p d\mu(a) \right)^{1/p} \right)^{1/p} \leq \rho w_p(x_i).$$

Since the discrete probabilities are (weak*-)-dense in $W(B_{F'})$ this implies that $S \in \mathcal{L}(E, F)$ is $(s, p)$-mixing iff there is a constant $\rho > 0$ such that for all finite families of elements $x_1, \ldots, x_n \in E$ and functionals $b_1, \ldots, b_m \in F'$

$$\left( \sum_{i=1}^{n} \left( \sum_{k=1}^{m} |(Sx_i, b_k)|^p \right)^{1/p} \right)^{1/p} \leq \rho w_p(x_i)(b_k).$$

Again the infimum over all possible $\rho$ equals $\mu_{s, p}(S)$ (compare with [22, 20.1.4]).

Now we recall some basic examples. An immediate consequence of the domination theorem is the following quotient formula

$$[\mathcal{M}_s, p, \mu_{s, p}] = [\mathcal{R}_s^{-1}, \mathcal{R}_p, \pi_s^{-1}, \pi_p], \quad 1 \leq p \leq s \leq \infty.$$
Moreover, the preceding quotient formula can be dualized as follows (cf. [22, 20.3.2])

\[
\mathcal{M}_{s,p} \cup \mathcal{M}_{s,p} = [\mathcal{N}_{s} \cdot \mathcal{N}_{p}^{-1}, N_{s} \cdot N_{p}^{-1}], \quad 1 \leq p \leq s \leq \infty,
\]
i.e., an operator \( S \in \mathscr{L}(E, F) \) is \((s, p)\)-mixing iff \( ST \in \mathcal{N}_{s}(X, F) \) for every operator \( T \in \mathcal{N}_{p}(X, E) \), and in this case

\[
\mu_{s,p}(S) = \sup\{ N_{s}(ST) | N_{p}(T) \leq 1 \}.
\]
The next result again due to Maurey [16] shows that the notions of \((s, p)\)-mixing and absolutely \((r, p)\)-summing operators are closely related. One has

\[
[\mathcal{N}_{s} \cup \mathcal{N}_{r}, \mathcal{N}_{s} \cup \mathcal{N}_{r}, p] \subseteq [\mathcal{N}_{s} \cup \mathcal{N}_{r}, \mathcal{N}_{s} \cup \mathcal{N}_{r}, p], \quad \frac{1}{s} + \frac{1}{r} = \frac{1}{p};
\]
(for an easy direct proof see [24]) and for \( 0 < p < s < 2 \) this inclusion is strict. However, for \( 1 \leq p \leq s_{0} < s \leq \infty \) and \( \frac{1}{s} + \frac{1}{r} = \frac{1}{p} \)

\[
[\mathcal{N}_{s} \cup \mathcal{N}_{r}, \mathcal{N}_{s} \cup \mathcal{N}_{r}, p] \subseteq [\mathcal{N}_{s_{0}} \cup \mathcal{N}_{r}, \mathcal{N}_{s_{0}} \cup \mathcal{N}_{r}, p]
\]
(cf. [22, 20.1.11 and 20.1.12]).

Finally, we mention that the identity operator on every \( L_{q} \)-space \( (1 \leq q \leq 2) \) is \((2, p)\)-mixing \((0 < p \leq 2)\). This result is due to Kwapien [13] and was extended by Maurey [16]:

\[
id_{E} \in \mathcal{M}_{2,p} \text{ for all } 0 < p \leq 2, \text{ if } E \text{ has cotype 2}
\]
(see also [22, 21.4.9 and 20.1.15]). A Banach space \( E \) has cotype \( q \) \((2 \leq q < \infty)\) if there is a constant \( c \geq 0 \) such that for finitely many \( x_{1}, \ldots, x_{n} \in E \)

\[
\left( \sum_{i=1}^{n} \|x_{i}\|^{q} \right)^{1/q} \leq c \left( \int_{0}^{1} \left\| \sum_{i=1}^{n} r_{i}(t) x_{i} \right\|^{2} dt \right)^{1/2},
\]
where \( r_{i} \) is the \( i \)-th Rademacher function. Khinchine's inequality shows that every \( L_{q} \)-space \( (1 \leq q < \infty) \) has cotype \( \max\{q, 2\} \). For further information on this notion we refer to [20].

For a Banach space \( E \) with \( \text{id}_{E} \in \mathcal{M}_{2,p} \) we put \( \mu_{s,p}(E) := \mu_{s,p}(\text{id}_{E}) \). The following estimates are known (cf. [22, 22.3.6])

\[
\mu_{2,p}(l_{q}) \leq \begin{cases} 
2^{q}c_{2}c_{p}^{-1} & \text{for } 1 < q \leq 2, 0 < p < 2, \\
2^{p}c_{2}c_{q}^{-1} & \text{for } 1 \leq q \leq 2, 1 < p < 2,
\end{cases}
\]
where

\[
c_{2p} = 2 \left[ \Gamma \left( \frac{1+p}{2} \right) \right]^{1/p}, \quad c_{2q} = \sqrt{2}, \quad c_{21} = \frac{2}{\sqrt{\pi}} (K = \mathbb{R}),
\]
\[
C_{2p} = 2 \left[ \Gamma \left( \frac{2+p}{2} \right) \right]^{1/p}, \quad c_{22} = 2, \quad c_{21} = \sqrt{\pi} (K = \mathbb{C}).
\]

1.2. Mixing operators and Weyl numbers. The following lemma combines the theory of \((s, p)\)-mixing operators with the concept of Weyl numbers. We just briefly recall some basic notions (for the general theory of \( s \)-numbers see the monographs [11, 23]).
The $n$th approximation number $a_n(S)$ of $S \in \mathcal{L}(E, F)$ is defined by
\begin{equation*}
a_n(S) := \inf \{ \| S - T \| : T \in \mathcal{L}(E, F) \text{ with rank } T < n \}
\end{equation*}
and the $n$th Weyl number $\lambda_n(S)$ is defined by
\begin{equation*}
\lambda_n(S) := \sup \{ a_n(SX) : X \in \mathcal{L}(l_2, E) \text{ with } \| X \| \leq 1 \}.
\end{equation*}
Clearly, the sequences $(a_n(S))$ and $(\lambda_n(S))$ are nonincreasing and $\|S\| = a_1(S) = \lambda_1(S)$. Moreover, they are multiplicative, i.e., $s_{n+m-1}(TS) \leq s_n(T)s_m(S)$, for $s \in \{a, \lambda\}$, $S \in \mathcal{L}(E, G)$, $T \in \mathcal{L}(G, F)$, and $n, m \in \mathbb{N}$. 

Given $0 < r < \infty$ and $0 < q < \infty$ the Lorenz sequence space $l_{r,q}$ is defined by
\begin{equation*}
l_{r,q} := \left\{ \xi \in l_\infty : |\xi|_r := \left( \sum_{k=1}^{\infty} k^{q/r-1} \xi_k^q \right)^{1/q} < \infty \right\},
\end{equation*}
where $(\xi_k^n)$ denotes the decreasing rearrangement of $|\xi_k|$. For $q = \infty$ the requirement is supposed to mean
\begin{equation*}
l_{r,\infty}(\xi) := \sup_{k \in \mathbb{N}} k^{1/r} \xi_k \leq \infty.
\end{equation*}
Clearly, $l_r := l_{r,r}$. The spaces $l_{r,q}$ are ordered lexicographically. For $s \in \{a, \lambda\}$ and $0 < r < \infty$, $0 < q \leq \infty$ let
\begin{equation*}
\mathfrak{s}^s_{r,q} := \{ S \in \mathcal{L}^r | L_{r,q}(S) := l_{r,q}(\|a(S)\|) < \infty \}
\end{equation*}
be the quasi Banach ideal of all operators with approximation numbers resp. Weyl numbers belonging to $l_{r,q}$.

We now establish a close relationship between the Banach ideal $\mathfrak{s}_{r,2}$ and certain Weyl number ideals. This result extends (and is also based on) the inclusions
\begin{equation*}
L_{r,1} \subseteq \mathcal{P}_r \subseteq L_{r,\infty}, \quad 2 \leq r < \infty,
\end{equation*}
which are crucial for the theory of eigenvalue distribution of compact operators and go back to König, Lewis, Pisier and Pietsch (see e.g. [11, 2.a.11 or 23, 2.7.4]). Moreover,
\begin{equation*}
L_{r,\infty} \leq \pi_{r,2} \quad \text{and} \quad \pi_2 \leq 12 L_{r,1}.
\end{equation*}

1.2.1. Proposition. Let $\frac{1}{s} + \frac{1}{r} = \frac{1}{2}$.

\begin{enumerate}
\item \( \mathcal{L}^s_{r,1} \subseteq \mathfrak{s}_{s,2} \) and \( \mu_{s,2} \leq 24 L^s_{r,1} \).
\item For every finite rank operator $S$, \( \mu_{s,2}(S) \leq 24(1 + \log(\text{rank } S)) L^s_{r,\infty}(S) \).
\end{enumerate}

Proof. In order to prove (1) by (1.1.3) it suffices to check $\mathcal{P}_s \cdot \mathcal{L}^s_{r,1} \subseteq \mathcal{P}_2$. 

Let $S \in \mathcal{L}^s_{r,1}(E, F)$ and $T \in \mathcal{P}_s(F, Y) \subseteq \mathcal{P}_{s,2}(F, Y) \subseteq \mathcal{L}^s_{s,\infty}(F, Y)$.

By the monotonicity and multiplicativity of the Weyl numbers $TS \in \mathcal{L}^s_{2,1}$, since
\begin{align*}
\sum_{k=1}^{\infty} k^{-1/2} x_k(TS) &\leq 2 \sum_{k} (2k - 1)^{-1/2} x_k(T)x_k(S) \\
&\leq 2 L^s_{s,\infty}(T)L^s_{r,1}(S) \\
&\leq 2 \pi_s(T)L^s_{r,1}(S).
\end{align*}

Hence $TS \in \mathcal{P}_2$ and
\begin{equation*}
\pi_2(TS) \leq 12 L^s_{2,1}(TS) \leq 24 \pi_s(T)L^s_{r,1}(S).
\end{equation*}
This completes the proof of (1). The proof of (2) is now easy, since for a given $S$ with $\text{rank} S = n$

$$L_{r,1}(S) = \sum_{k=1}^{n} k^{-1} k^{1/r} x_k(S) \leq (1 + \log n) L_{r,\infty}(S). \quad \Box$$

We finally remark that the preceding proposition can be used to reprove the following special (but most important) case of a deep result of Maurey [17] (for the full statement see (1.1.6)).

1.2.2. **Corollary.** Let $2 \leq s_0 < s < \infty$ and $\frac{1}{s} + \frac{1}{r} = \frac{1}{2}$. Then $\mathcal{P}_{r,2} \subseteq \mathcal{M}_{s_0,2}$.

**Proof.** Define $2 \leq r < r_0 \leq \infty$ by $1/s_0 + 1/\mathbf{r}_o = \frac{1}{2}$. Then $\mathcal{L}_{r,\infty} \subseteq \mathcal{L}_{r_0,1}$, and therefore part (1) of the proposition implies $\mathcal{P}_{r,2} \subseteq \mathcal{L}_{r_0,1} \subseteq \mathcal{M}_{s_0,2}$. \( \Box \)

1.3. **A tensor multiplicativity concept.** A simple but striking concept is presented which is a useful tool to improve various kinds of inequalities and furnishes the foundation for many modern results in summability and eigenvalue theory.

A subset $\mathcal{S}$ of operators $S : \mathbb{K}^n \rightarrow \mathbb{K}^n$ (where $n \in \mathbb{N}$ is arbitrary) is called tensor stable if for all $S \in \mathcal{S} (\mathbb{K}^n, \mathbb{K}^n)$ the tensor product operator

$$S \otimes S : \mathbb{K}^n \otimes \mathbb{K}^n = \mathbb{K}^{n^2} \rightarrow \mathbb{K}^{n^2}$$

is again in $\mathcal{S}$ (identify $\mathbb{K}^n \otimes \mathbb{K}^n$ with $\mathbb{K}^{n^2}$ via the bijection $\varphi$ defined by $\varphi(e_i \otimes e_j) := e_{(n-1)i+j}$ for $1 \leq i, j \leq n$). Moreover, let $A : \mathcal{A} \rightarrow \mathbb{R}^+$ be a function and $a \geq 0$. Then $A$ is said to be $a$-tensor supermultiplicative if for all $S \in \mathcal{A}$

$$A(S)^2 \leq aA(S \otimes S),$$

whereas it is called $a$-tensor submultiplicative if

$$A(S \otimes S) \leq aA(S)^2,$$

for all $S \in \mathcal{A}$. The following simple lemma is essential.

1.3.1. **Lemma.** Let $\mathcal{S}$ be a tensor stable set of operators $S : \mathbb{K}^n \rightarrow \mathbb{K}^n$ and $\lambda \geq 0$. Moreover, let $A : \mathcal{A} \rightarrow \mathbb{R}^+$ be $a$-tensor supermultiplicative and $B : \mathcal{A} \rightarrow \mathbb{R}^+$ be $b$-tensor submultiplicative such that for each $\varepsilon > 0$ there is $c(\varepsilon) \geq 0$ satisfying

$$(*) \quad A(S) \leq c(\varepsilon) n^{\lambda+\varepsilon} B(S)$$

for all $n \in \mathbb{N}$ and $S \in \mathcal{A} (\mathbb{K}^n, \mathbb{K}^n)$. Then for all $n \in \mathbb{N}$ and $S \in \mathcal{A} (\mathbb{K}^n, \mathbb{K}^n)$

$$A(S) \leq abn^\lambda B(S).$$

**Proof.** Fix $\varepsilon > 0$. Then there is $c(\varepsilon) \geq 0$ such that for all $n \in \mathbb{N}$ and $S \in \mathcal{A} (\mathbb{K}^n, \mathbb{K}^n)$

$$A(S)^2 \leq aA(S \otimes S) \leq ac(\varepsilon) n^{2(\lambda+\varepsilon)} B(S \otimes S) \leq abc(\varepsilon) n^{2(\lambda+\varepsilon)} B(S)^2,$$

and hence

$$A(S) \leq (ab)^{1/2} c(\varepsilon)^{1/2} n^{\lambda+\varepsilon} B(S).$$

By iteration of this result ($c(\varepsilon)$ in (*) can be replaced by $(ab)^{1/2} c(\varepsilon)^{1/2}$) we get for all $k, n \in \mathbb{N}$ and $S \in \mathcal{A} (\mathbb{K}^n, \mathbb{K}^n)$

$$A(S) \leq (ab)^k c(\varepsilon)^{k/2} n^{\lambda+\varepsilon} B(S).$$
Therefore, if for a fixed $S \in \mathcal{A}(\mathbb{K}^n, \mathbb{K}^n)$ first $k$ tends to infinity and then $\varepsilon$ tends to zero the described inequality is obtained. □

The conclusion of the lemma holds in particular, if instead of (*) there are constants $\lambda, c \geq 0$ such that for all $n \in \mathbb{N}$ and $S \in \mathcal{A}(\mathbb{K}^n, \mathbb{K}^n)$

$$A(S) \leq cn^\lambda(1 + \log n)B(S).$$

Moreover, we mention that the idea of using tensor product techniques to improve constants in certain inequalities goes back to Russo [25]. Recently, Pietsch [23] used similar tensor multiplicativity techniques to improve various eigenvalue estimates of operators.

Two of our main results will follow from the next lemma which is an immediate consequence of the preceding one.

1.3.2. Lemma. For $1 \leq u, v < \infty$ and $0 < r < \infty$ let $[\mathcal{A}, A], [\mathcal{B}, B]$ be two quasi-Banach ideals such that

$$\mathcal{L}^{\infty}(l_u, l_v) \subseteq \mathcal{A}(l_u, l_v) \quad \text{and} \quad \mathcal{B}(l_u, l_v) \subseteq \mathcal{L}^{\infty}(l_u, l_v).$$

Moreover, assume that there are constants $a, b \geq 1$ with

$$A(S)^2 \leq aA(S \otimes S : l_u^{n^2} \rightarrow l_v^{n^2}),$$

$$B(S \otimes S : l_u^{n^2} \rightarrow l_v^{n^2}) \leq bB(S)^2,$$

for all $n \in \mathbb{N}$ and $S \in \mathcal{L}(l_u^n, l_v^n)$. Then for all $n \in \mathbb{N}$ and $S \in \mathcal{L}(l_u^n, l_v^n)$

$$A(S) \leq abB(S).$$

Proof. By the closed graph theorem there are constants $c, d \geq 1$ such that for all $S \in \mathcal{L}(l_u^n, l_v^n)$

$$A(S) \leq cL_{r, 1}^{\infty}(S) \leq c(1 + \log n)L_{r, \infty}^{\infty}(S) \leq cd(1 + \log n)B(S).$$

Now the conclusion follows, if we apply the lemma to the set of all operators $S : \mathbb{K}^n \rightarrow \mathbb{K}^n$, the $a$-tensor supermultiplicative function

$$A : S \mapsto A(S : l_u^n \rightarrow l_v^n),$$

and the $b$-tensor submultiplicative function

$$B : S \mapsto B(S : l_u^n \rightarrow l_v^n).$$ □

Finally, we mention

1.3.3. Lemma. Let $1 \leq u, v \leq \infty$ and let $[\mathcal{A}, A]$ be a quasi-Banach ideal. Assume that there is a constant $a \geq 1$ such that for all $n \in \mathbb{N}$

$$A(\text{id} : l_u^n \rightarrow l_v^n)^2 \leq aA(\text{id} : l_u^{n^2} \rightarrow l_v^{n^2}).$$

Then either

$$\sup_{n \in \mathbb{N}} A(\text{id} : l_u^n \rightarrow l_v^n) \leq a;$$

or there is $\varepsilon > 0$ such that for large $n$

$$n^\varepsilon \leq A(\text{id} : l_u^n \rightarrow l_v^n).$$

Proof. Assume that there is $1 \neq n_0 \in \mathbb{N}$ such that

$$A(\text{id} : l_u^{n_0} \rightarrow l_v^{n_0}) > a.$$
Put $d := a^{-1}A(id : l_u^{n_0} \to l_v^{n_0})$ and $\varepsilon := \frac{1}{2}\log_{n_0} d > 0$. Moreover, for $n \geq n_0$ choose $m \in \mathbb{N}_0$ such that $n_0^{2\varepsilon m} \geq n \geq n_0^{2\varepsilon}$. Then the conclusion follows from

$$A(id : l_u^n \to l_v^{n}) \geq A(id : l_u^{n_0} \to l_v^{n_0}) \geq ad^m = a(n_0^{\log_{n_0} d})^m = a(n_0^{2\varepsilon})^m \geq an^\varepsilon.$$

1.4. Tensor multiplicativity of some ideal norms. In this section we investigate tensor submultiplicativity of the operator norm and tensor supermultiplicativity of the $(s, p)$-mixing norm with respect to tensor products of $L_p$-spaces. In particular, we extend results of Bennett [3].

The $\varepsilon$-norm and $\pi$-norm of $z \in E \otimes F$ are denoted by

$$\varepsilon(z; E, F) := \sup\{|(z, a \otimes b)| \mid a \in B_{E'}, b \in B_{F'}\},$$

$$\pi(z; E, F) := \inf\left\{\sum_{i=1}^n \|x_i\| \|y_i\| \mid z = \sum_{i=1}^n x_i \otimes y_i \right\}.$$  

Obviously, $\varepsilon(\cdot; E, F) \leq \pi(\cdot; E, F)$. A norm $\alpha(\cdot; E, F)$ on $E \otimes F$ is called reasonable, if

$$\varepsilon(\cdot; E, F) \leq \alpha(\cdot; E, F) \leq \pi(\cdot; E, F).$$

By $E \otimes_\alpha F$ we denote the completion of the normed space

$$E \otimes_\alpha F := (E \otimes F, \alpha(\cdot; E, F)).$$

It can be seen easily that a given norm $\alpha(\cdot; E, F)$ on $E \otimes F$ is reasonable if and only if for all $x \in E$, $y \in F$, $\alpha(x \otimes y; E, F) = \|x\| \|y\|$, and for all $a \in E'$, $b \in F'$, $z \in E \otimes F$, $|(z, a \otimes b)| \leq \|a\| \|b\| \alpha(z; E, F)$.

Let us give two examples: For $1 \leq p \leq \infty$ and $z \in E \otimes F$

$$g_p(z; E, F) := \inf\left\{l_p(x_i) w_p(y_i) \mid z = \sum_{i=1}^n x_i \otimes y_i \right\},$$

and if $T_z \in \mathcal{L}(E', F)$ denotes the operator corresponding to $z$

$$g_p^*(z; E, F) := \pi_{p'}(T_z : E' \to F).$$

Both norms are reasonable and were intensively studied by Chevet, Cohen, and Saphar (see e.g. [6, 7, 26]). One has

$$g_p^*(z; E, F) = \pi_p(T_z : E' \to F) \leq N_p(T_z : E' \to F) \leq g_p(z; E, F),$$

and equality for $p = 2$. Moreover, for $1 \leq p \leq q \leq \infty$

$$g_q(z; E, F) \leq g_p(z; E, F),$$

$$g_q^*(z; E, F) \leq g_p^*(z; E, F).$$

Obviously $\alpha = g_p$ (resp. $\alpha = g_q^*$) satisfies the metric mapping property: for $T \in \mathcal{L}(E, X)$ and $S \in \mathcal{L}(F, Y)$

$$\|S \otimes T : E \otimes_\alpha F \to X \otimes_\alpha Y\| = \|S\| \|T\|.$$
whereas for two arbitrary reasonable norms \( \alpha(\cdot; E, F) \) and \( \beta(\cdot; E, F) \) just the following estimate holds:

\[
\| S \| \| T \| = \sup \{ \beta(Sx \otimes Ty ; X, Y) \mid \alpha(x \otimes y ; E, F) \leq 1 \}
\leq \sup \{ \beta(S \otimes T(z) ; X, Y) \mid \alpha(z ; E, F) \leq 1 \}
= \| S \otimes T : E \otimes \alpha F \rightarrow X \otimes \beta Y \|
\]

(provided \( S \otimes T : E \otimes \alpha F \rightarrow X \otimes \beta Y \) is continuous). For special norms we prove

1.4.1. Proposition. For \( 1 \leq u, v \leq \infty \) let \( \alpha(\cdot; E, F) \geq g_u(\cdot; E, F) \) and \( \beta(\cdot; X, Y) \leq g_v^*(\cdot; X, Y) \) be reasonable norms. Moreover, let \( S \in \mathcal{L}(E, X) \) and \( T \in \mathcal{L}(F, Y) \).

(1) If \( 1 \leq u \leq v \leq \infty \) then

\[
\| S \otimes T : E \otimes \alpha F \rightarrow X \otimes \beta Y \| \leq \| S \| \| T \| .
\]

(2) In each of the three cases

(a) \( 2 = v \leq u \leq \infty \) and \( Y \) has cotype 2,

(b) \( 1 \leq v \leq u = 2 \) and \( E' \) has cotype 2,

(c) \( 1 \leq u < 2 < v \leq \infty \) and \( E', Y \) have cotype 2

one has

\[
\| S \otimes T : E \otimes \alpha F \rightarrow X \otimes \beta Y \| \leq \mu_{2,v}(E')\mu_{2,u}(Y)\| S \| \| T \| .
\]

Proof. Obviously it is sufficient to prove the assertion just for \( \alpha = g_u \) and \( \beta = g_v^* \). Statement (1) follows by

\[
g_v^*(S \otimes T(z) ; X, Y) \leq g^*_u(S \otimes T(z) ; X, Y)
\leq g_u(S \otimes T(z) ; X, Y)
\leq \| S \| \| T \| g_u(z ; E, F).
\]

For the proof of (2)(a) consider the commutative diagram

\[
\begin{array}{ccc}
E \otimes g_u F & \xrightarrow{S \otimes T} & X \otimes g^*_2 Y \\
\downarrow \text{id} \otimes T & & \uparrow S \otimes \text{id} \\
E \otimes g_2 Y & = & E \otimes g^*_2 Y.
\end{array}
\]

Then by (1.1.4') and (1.1.7)

\[
\| S \otimes T : E \otimes g_u F \rightarrow X \otimes g^*_2 Y \|
\leq \| S \| \sup \{ g_2(\text{id} \otimes T(z) ; E, Y) \mid g_u(z ; E, F) \leq 1 \}
\leq \| S \| \sup \{ N_2(TR : E' \rightarrow Y) \mid N_u(R : E' \rightarrow F) \leq 1 \}
\leq \| S \| \mu_{2,v}(T : F \rightarrow Y) \leq \mu_{2,v}(Y)\| S \| \| T \| .
\]

Dually: Under the assumption of (b) by (1.1.3') and (1.1.7)

\[
\| S \otimes T : E \otimes g_2 F \rightarrow X \otimes g^*_v Y \|
\leq \| T \| \sup \{ g^*_v(S \otimes \text{id}(z) ; X, Y) \mid g^*_2(z ; E, Y) \leq 1 \}
\leq \| T \| \sup \{ \pi_v(RS' : X' \rightarrow Y) \mid \pi_2(R : E' \rightarrow Y) \leq 1 \}
\leq \| T \| \mu_{2,v}(S' : X' \rightarrow E') \leq \mu_{2,v}(E')\| S \| \| T \| .
\]
Finally, assume that $1 \leq v < 2 < u \leq \infty$ and that $E', Y$ have cotype 2. Then the diagram

\[
\begin{array}{cccc}
E \otimes_{g_e} F & \xrightarrow{S \otimes T} & X \otimes_{g_e'} Y \\
\downarrow \text{id} \otimes T & & \downarrow S \otimes \text{id} \\
E \otimes_{g_e'} Y & = & E \otimes_{g_e'} Y,
\end{array}
\]

commutes, and hence the assertion is an immediate consequence of (2)(a) and (2)(b). \( \square \)

Let $L_p = L_p(\Omega, \Sigma, \mu)$ be an $L_p$-space $(1 \leq p \leq \infty)$. For $z = \sum_{i=1}^n x_i \otimes g_i \in E \otimes L_p$ we define

\[
\Delta_p(z; E, L_p) := \left( \int \left\| \sum x_i \otimes g_i \right\|^p d\mu \right)^{1/p};
\]

and for $z = \sum_{i=1}^n f_i \otimes y_i \in L_p \otimes F$

\[
\Delta_p(z; L_p, F) := \Delta_p \left( \sum_{i} y_i \otimes f_i; F, L_p \right)
\]

(with the usual modifications for $p = \infty$). Then $\Delta_p(\cdot; E, L_p)$ and $\Delta_p(\cdot; L_p, F)$ are reasonable norms and it is well known that (see e.g. [19, 27])

- $g_p(\cdot; E, L_p) \leq \Delta_p(\cdot; E, L_p)$,
- $\Delta_p(\cdot; L_p, F) \leq g_p^*(\cdot; L_p, F)$,
- $g_1(\cdot; E, L_1) = \Delta_1(\cdot; E, L_1) = \pi(\cdot; E, L_1)$,
- $\Delta_\infty(\cdot; L_\infty, F) = g_1^*(\cdot; L_\infty, F) = \varepsilon(\cdot; L_\infty, F)$.

Hence the preceding proposition has the following corollary which is a proper extension of a result due to Bennett [3].

1.4.2. **Corollary.** Let $S \in \mathcal{L}(E, L_v)$ and $T \in \mathcal{L}(L_u, F)$.

- (1) If $1 \leq u \leq v \leq \infty$, then
  \[ \| S \otimes T : E \otimes_{\Delta_u} L_u \to L_v \otimes_{\Delta_v} F \| \leq \| S \| \| T \|. \]
  
  (2) In each of the three cases
  
  (a) $2 = v \leq u \leq \infty$ and $F$ has cotype 2,
  
  (b) $1 \leq v \leq u = 2$ and $E'$ has cotype 2,
  
  (c) $1 \leq v < 2 < u \leq \infty$ and $E', F$ have cotype 2

one has

\[ \| S \otimes T : E \otimes_{\Delta_u} L_u \to L_v \otimes_{\Delta_v} F \| \leq \mu_{2, v}(E') \mu_2, w(F) \| S \| \| T \|. \]

We remark that this result (in contrast to Bennett's) still includes a variant of Grothendieck’s Theorem namely:

\[
\pi_2(S : l_\infty \to l_1) = \| \text{id} \otimes S : l_2 \otimes_{\Delta_2} l_\infty \to l_2 \otimes_{\Delta_2} l_1 \|
\]

\[
= \| \text{id} \otimes S : l_2 \otimes_{\Delta_\infty} l_\infty \to l_2 \otimes_{\Delta_2} l_1 \|
\]

\[
\leq \mu_{2, 1}(l_1) \| S \| .
\]
It was already noted by Bennett [3] that in the cases $1 < v < u < 2$ and $2 < v < u \leq \infty$ an inequality of the form
\[ \| S \otimes S : l_u^{n^2} \to l_v^{n^2} \| \leq c(u, v)\| S \|^2 \]
does not hold, where $c(u, v)$ is a constant just depending on $u$ and $v$ (see also [22, 22.4.13, second remark]).

We now formulate another special case of 1.4.1.

1.4.3. Corollary. Let $\alpha(\cdot; E, F) \leq g_u^*(\cdot; E, F)$ be a reasonable norm, $x_1, \ldots, x_n \in E$ and $y_1, \ldots, y_n \in F$.

(1) If $1 \leq p' \leq u \leq \infty$, then
\[ w_p(x_i \otimes y_j; E \tilde{\otimes}_\alpha F) \leq w_p(x_i)w_p(y_j). \]

(2) In each of the two cases
\begin{enumerate}
  \item $1 \leq u \leq p' = 2$,
  \item $1 \leq u \leq 2 < p' \leq \infty$ and $F$ has cotype 2
\end{enumerate}
one has
\[ w_p(x_i \otimes y_j; E \tilde{\otimes}_\alpha F) \leq \mu_{2, u}(l_p)\mu_{2, p}(F)w_p(x_i)w_p(y_j). \]

Proof. Define
\[ S := \sum_i e_i \otimes x_i \in \mathcal{L}(l_p^n, E), \quad T := \sum_j e_j \otimes y_j \in \mathcal{L}(l_p^n, F). \]
Then
\[ \| S \| = w_p(x_i), \quad \| T \| = w_p(y_j), \quad \| S \otimes T : l_p^{n^2} \to E \otimes_{\alpha} F \| = w_p(x_i \otimes y_j; E \tilde{\otimes}_\alpha F). \]
Hence the conclusions follow by 1.4.1 (replace $u$ by $p'$, $\alpha$ by $\Delta_{p'}$ and $\beta$ by $\alpha$). \qed

We are now ready to study tensor supermultiplicativity of the $(s, p)$-mixing norm. The following proposition and its corollary will play a crucial role for the proofs of our applications. First we set up the following notation: If $S \in \mathcal{L}(E, X)$ and $T \in \mathcal{L}(F, Y)$ are two operators of finite rank, then $S \otimes T : E \otimes_{\alpha} F \to X \otimes_{\beta} Y$, where $\alpha(\cdot; E, F)$ and $\beta(\cdot; X, Y)$ are reasonable norms, is again a continuous operator of finite rank. Hence it has a continuous extension $S \tilde{\otimes} T : E \tilde{\otimes}_\alpha F \to X \tilde{\otimes}_{\beta} Y$.

1.4.4. Proposition. Let $\alpha(\cdot; E, F) \leq g_u^*(\cdot; E, F)$ and $\beta(\cdot; X, Y)$ be reasonable norms. Moreover, let $S \in \mathcal{L}(E, X)$ and $T \in \mathcal{L}(F, Y)$ be operators of finite rank.

(1) If $1 \leq p' \leq u \leq \infty$, then
\[ \mu_{s, p}(S)\mu_{s, p}(T) \leq \mu_{s, p}(S \tilde{\otimes} T : E \tilde{\otimes}_\alpha F \to X \tilde{\otimes}_{\beta} Y). \]

(2) In each of the two cases
\begin{enumerate}
  \item $1 \leq u \leq p' = 2$,
  \item $1 \leq u \leq 2 < p' \leq \infty$ and $F$ has cotype 2
\end{enumerate}
one has
\[ \mu_{s,p}(S)\mu_{s,p}(T) \leq \mu_{2,u}(l_p)\mu_{2,p}(F)\mu_{s,p}(S\otimes T : E\otimes\alpha F \to X\otimes\beta Y). \]

Proof. Fix \( x_1, \ldots, x_m \in E, y_1, \ldots, y_m \in F, a_1, \ldots, a_m \in X', \) and \( b_1, \ldots, b_m \in Y'. \) Then by (1.1.2)
\[
\left( \sum_{i=1}^{m} \left( \sum_{k=1}^{m} |(Sx_i, a_k)^s|^{p/s} \right)^{1/p} \right)^{p/s} \left( \sum_{j=1}^{m} \left( \sum_{l=1}^{m} |(Ty_j, b_l)^s|^{p/s} \right)^{1/p} \right)^{p/s} \leq \mu_{s,p}(S\otimes T : E\otimes\alpha F \to X\otimes\beta Y) \\
\cdot \omega_p(x_i \otimes y_j ; E\otimes\alpha F)l_s(a_k \otimes b_l ; (X\otimes\beta Y)'),
\]
and since \( \beta \) is a reasonable norm on \( X \otimes Y \)
\[ l_s(a_k \otimes b_l ; (X\otimes\beta Y)') = l_s(a_k)l_s(b_l). \]
Hence both assertions follow from the preceding corollary. \( \square \)

Exactly in the same way it can be shown that
\[ \pi_{r,p}(S)\pi_{r,p}(T) \leq \pi_{r,p}(S\otimes T : E\otimes\alpha F \to X\otimes\beta Y), \]
for \( 1 < p' < u \leq \infty, \) and
\[ \pi_{r,p}(S)\pi_{r,p}(T) \leq \mu_{2,u}(l_p)\mu_{2,p}(F)\pi_{r,p}(S\otimes T : E\otimes\alpha F \to X\otimes\beta Y), \]
for \( 1 \leq u \leq p' = 2 \) or \( 1 \leq u \leq 2 < p' \leq \infty, \) provided \( F \) has cotype 2.

1.4.5. Corollary. Let \( S \in \mathcal{L}(l^n_u, X), T \in \mathcal{L}(l^n_u, Y) \) and let \( \beta \) be a reasonable norm on \( X \otimes Y \).

1. If \( 1 \leq p' \leq u \leq \infty, \) then
\[ \mu_{s,p}(S)\mu_{s,p}(T) \leq \mu_{s,p}(S\otimes T : l^n_u \to X\otimes\beta Y). \]

2. If \( 1 \leq u \leq 2 \leq p' \leq \infty, \) then
\[ \mu_{s,p}(S)\mu_{s,p}(T) \leq \mu_{2,u}(l_p)\mu_{2,p}(l_u)\mu_{s,p}(S\otimes T : l^n_u \to X\otimes\beta Y). \]

Since the case \( p = 2 \) is the most important for applications we once more refer to the upper estimates of \( \mu_{2,u}(l_2) \) for \( 1 \leq u \leq 2, \) mentioned at the end of 1.1.

2. INTEGRAL CHARACTERIZATIONS OF OPERATOR IN \( L_p \) SPACES

Now we are ready to prove our main results: integral characterizations of
- operators from \( L_1 \)-spaces into \( L_u \)-spaces,
- Schatten-von Neumann operators,
- identity operators from \( l_u \) into \( l_2 \).
2.1. Operators from $L_1$-spaces into $L_v$-spaces. The following important fact was discovered by Kwapien [12] (see also [3]).

Let $1 \leq v \leq \infty$, $0 < p \leq 2$ and $1 \leq p \leq r \leq \infty$. If $\frac{1}{r} \leq \frac{1}{p} - \frac{1}{2 - \frac{1}{v}}$ then

$$\mathcal{L}(l_1, l_v) = \mathcal{P}_{r, p}(l_1, l_v).$$

Moreover, this result is best possible in the sense that if $r$ fails to satisfy the inequality $\frac{1}{r} \leq \frac{1}{p} - \frac{1}{2 - \frac{1}{v}}$ then $\mathcal{L}(l_1, l_v) \neq \mathcal{P}_{r, p}(l_1, l_v)$.

By use of an inclusion formula for absolutely $(r, p)$-summing operators (mentioned in the preliminary section) the proof can be restricted to the case $p = 1$. In order to prove this case Kwapien interpolates between the points $v = 1, 2, \infty$. The cases $p = 1, v = 1$ and $p = 1, v = \infty$ are consequences of a result of Orlicz [18], which states that the identity operator on $l_1$ is absolutely $(2, 1)$-summing, whereas the case $p = 1, v = 2$ obviously is Grothendieck's Theorem [9].

We now state a proper extension of Kwapien's result.

2.1.1. Theorem. Let $1 \leq v \leq \infty$ and $0 < p \leq 2 \leq s \leq \infty$ such that $\frac{1}{s} = \frac{1}{2} - \frac{1}{v}$. Then

$$\mathcal{L}(l_1, l_v) = \mathcal{M}_{s, p}(l_1, l_v),$$

and for all $S \in \mathcal{L}(l_1, l_v)$

$$\mu_{s, p}(S) \leq k(p)\|S\|,$$

where $k(p) := \mu_{2, p}(l_1)\mu_{2, 1}(l_2)$. In other words, for every $S \in \mathcal{L}(l_1, l_v)$ and every probability measure $\mu \in W(B_{l_v})$ there is a probability measure $\nu \in W(B_{l_\infty})$ such that for all $x \in l_1$

$$\left( \int |\langle Sx, a \rangle|^s d\mu(a) \right)^{1/s} \leq k(p) \left( \int |\langle x, a \rangle|^p d\nu(a) \right)^{1/p},$$

(with the obvious modifications if $v = \infty$ or $s = \infty$).

Proof. Since

$$[\mathcal{M}_{s, 2} \cdot \mathcal{M}_{2, p}, \mu_{s, 2} \cdot \mu_{2, p}] \subseteq [\mathcal{M}_{s, p}, \mu_{s, p}]$$

and $id_{l_1} \in \mathcal{M}_{s, p}$ for $0 < p < 2$ (see 1.1.1 and 1.1.7), it suffices to prove the assertion for $p = 2$. Define $2 \leq r \leq \infty$ by $\frac{1}{s} + \frac{1}{r} = \frac{1}{2}$. By 1.2.1 Proposition we know $\mathcal{L}_{r, 1}(l_1, l_v) \subseteq \mathcal{M}_{s, 2}(l_1, l_v)$, and by Kwapien's theorem $\mathcal{L}(l_1, l_v) = \mathcal{P}_{r, 2}(l_1, l_v) \subseteq \mathcal{L}_{r, \infty}(l_1, l_v)$.

Moreover, by 1.4.5(2) and 1.4.2(1) for all $S \in \mathcal{L}(l_1^n, l_v^n)$

$$\mu_{s, 2}(S)^2 \leq k(2)\mu_{s, 2}(S \otimes S : l_1^{n^2} \rightarrow l_v^{n^2}),$$

$$\|S \otimes S : l_1^{n^2} \rightarrow l_v^{n^2}\| \leq \|S\|^2.$$

Hence 1.3.2 Lemma implies that for all $S \in \mathcal{L}(l_1^n, l_v^n)$ $\mu_{s, 2}(S) \leq k(2)\|S\|$.

Let now $S \in \mathcal{L}(l_1, l_v)$. We use the local definition (1.1.2) in order to show that $S$ is $(s, 2)$-mixing. Fix $x_1, \ldots, x_m \in l_1$ and $b_1, \ldots, b_m \in l_v$ (for
For \( n \in \mathbb{N} \) define the operators
\[
S_n : l_1^n \to l_1^n, \\
P_n : l_1 \to l_1^n, \\
Q_n : l_v \to l_v^n,
\]
\[
(\xi_i) \mapsto (S(\xi_1, \ldots, \xi_n, 0, \ldots)), \\
(\xi_i) \mapsto (\xi_1, \ldots, \xi_n), \\
(\xi_i) \mapsto (\xi_1, \ldots, \xi_n).
\]

Then for all \( n \in \mathbb{N} \)
\[
\left( \sum_i \left( \sum_k |\langle S_n P_n x_i, Q_n b_k \rangle|^s \right)^{2/s} \right)^{1/2} \leq \mu_s, 2(S) w_2(P_n x_i) l_s(Q_n b_k) \leq k(2) ||S|| w_2(x_i) l_s(b_k).
\]

Since for fixed \( i \) and \( k \) \( \lim_{n \to \infty} |S_n P_n x_i, Q_n b_k| = |\langle S x_i, b_k \rangle| \), we get \( S \in \mathcal{M}_{s,2}(l_1, l_v) \) and \( \mu_{s,2}(S) \leq k(2) ||S|| \). \( \square \)

Following the local techniques of Lindenstrauss and Pelczyński [14] the theorem can be extended to operators acting between so-called \( \mathcal{L}_1, \lambda \)- and \( \mathcal{L}_v, \mu \)-spaces. A Banach space \( E \) is called an \( \mathcal{L}_q, \lambda \)-space (\( 1 \leq q \leq \infty, 1 \leq \lambda \leq \infty \)) if for every finite-dimensional subspace \( M \) of \( E \) there is a finite-dimensional subspace \( N \) of \( E \) such that \( M \subseteq N \) and the Banach-Mazur distance
\[
d(N, l_q^n) := \inf \{ \| T \| T^{-1} \| \ T \in \mathcal{L}(N, l_q^n) \text{ bijective} \} \leq \lambda,
\]
where \( n := \dim N \). Every \( L_q \)-space is an \( \mathcal{L}_q, \lambda \)-space for all \( \lambda > 1 \) and every space \( C(X) \), where \( X \) is compact, is an \( \mathcal{L}_{\infty, \lambda} \)-space for all \( \lambda > 1 \).

By use of 1.1.2 and standard (local) arguments the following extensions of 2.1.1 can be shown:

Let \( E \) be an \( \mathcal{L}_1, \lambda \)-space and \( F \) an \( \mathcal{L}_v, \mu \)-space (\( 1 \leq v \leq \infty \)). If \( 0 < p \leq 2 < s \leq \infty \) and \( \frac{1}{s} = \left( \frac{1}{s} - \frac{1}{v} \right) \) then \( \mathcal{L}(E, F) = \mathcal{M}_{s, p}(E, F) \), and for all \( S \in \mathcal{L}(E, F) \), \( \mu_{s, p}(S) \leq k(p) \lambda \mu ||S|| \).

Finally we note some interesting composition formulas (all of which are equivalent to our theorem). For this we need some more notation. The canonical embedding of a Banach space \( E \) into its bidual \( E'' \) will be denoted by \( K_E \).

Let \( 1 \leq p \leq \infty \). By definition \( \mathcal{L}_p \) is the ideal of all operators \( S \in \mathcal{L}(E, F) \) such that \( K_F S \) factors through an appropriate \( L_p \)-space. \( S \in \mathcal{L}(E, F) \) belongs to the ideal \( \mathcal{J}_p \) if there is a \( \mu \in W(B_{E'}) \) such that \( K_F S \) factors through the formal identity \( C(B_{E'}) \to L_p(\mu) \). Moreover, we write \( S \in \mathcal{P}_{p}^{\text{dual}}(E, F) \) if \( S' \in \mathcal{P}_p(F', E') \).

2.1.2. Corollary. Let \( 1 \leq v \leq \infty \) and \( 1 \leq p \leq 2 \leq s \leq \infty \). If \( \frac{1}{s} = \left( \frac{1}{s} - \frac{1}{v} \right) \) then
\[
(1) \mathcal{L}_v, \mathcal{L}_1 \subseteq \mathcal{M}_{s, p}, \\
(2) \mathcal{P}_s, \mathcal{L}_v, \mathcal{L}_1 \subseteq \mathcal{P}_p, \\
(3) \mathcal{L}_v, \mathcal{L}_1, \mathcal{J}_p \subseteq \mathcal{J}_s, \\
(4) \mathcal{L}_v, \mathcal{L}_1, \mathcal{N}_p \subseteq \mathcal{N}_s, \\
(5) \mathcal{J}_p, \mathcal{P}_s, \mathcal{L}_v \subseteq \mathcal{P}_v^{\text{dual}}, \mathcal{P}_v, \\
(6) \mathcal{J}_p, \mathcal{P}_s, \mathcal{L}_v \subseteq \mathcal{P}_1^{\text{dual}}.
\]
Sketch of the Proof. Let us first check (1). By definition for every $S \in \mathcal{L}_v \cdot \mathcal{L}_1(E, F)$ there are an $L_1$-space $L_1$, an $L_v$-space $L_v$ and operators $X \in \mathcal{L}(E'', L'')$, $U \in \mathcal{L}(L''_1, L''_v)$, $Y \in \mathcal{L}(L''_v, F'')$, such that the following diagram commutes:

$$
\begin{array}{ccc}
E'' & \xrightarrow{S''} & F'' \\
\downarrow X & & \downarrow Y \\
L''_1 & \xrightarrow{U} & L''_v.
\end{array}
$$

Now the bidual of $L_1$ resp. $L_v$ is an $\mathcal{L}_1, \lambda$-space resp. $\mathcal{L}_v, \lambda$-space for all $\lambda > 1$, and hence $U$ and in particular $S''$ are $(s, p)$-mixing. But since $S \in \mathcal{M}_{s, p}$ if $S'' \in \mathcal{M}_{s, p}$ (this is an immediate consequence of (1.1.2)), the proof of (1) is complete. The assertions (2), (3) and (4) now follow by the inclusion formulas

$$
\mathcal{P}_s \cdot \mathcal{M}_{s, p} \subseteq \mathcal{P}_p, \quad \mathcal{M}_{s, p} \cdot \mathcal{P}_p' \subseteq \mathcal{I}_s, \quad \mathcal{M}_{s, p} \cdot \mathcal{M}_{p'} \subseteq \mathcal{N}_s'
$$

(see (1.1.3), (1.1.4) and [22, 20.2]). Moreover, (3) implies

$$
\mathcal{L}_1 \cdot \mathcal{I}_{p'} \subseteq \mathcal{L}^{-1}_v \cdot \mathcal{I}_s = \mathcal{L}_v^* \cdot \mathcal{P}^{-1}_s = \mathcal{P}^\text{dual}_v \cdot \mathcal{P}_{s'} \cdot \mathcal{P}_{s}^{-1},
$$

where $\mathcal{L}_v^*$ denotes the adjoint ideal of $\mathcal{L}_v$ which by the Persson-Pietsch trace duality and a deep factorization theorem of Kwapien equals $\mathcal{P}^\text{dual}_v \cdot \mathcal{P}_{s'}$ (see [22, 17.4.3. and 19.3.10]). For the proof of the equality $\mathcal{L}^{-1}_v \cdot \mathcal{I}_s = \mathcal{L}_v^* \cdot \mathcal{P}^{-1}_s$ use e.g. the general quotient formula 4.4.2. of [8]. In a similar way (5) implies (6). □

2.2. Schatten-von Neumann classes. By definition the Schatten-von Neumann classes are

$$
\mathcal{A}_r(l_2, l_2) := \mathcal{L}_r^a(l_2, l_2), \quad 0 < r < \infty.
$$

For $S \in \mathcal{A}_r(l_2, l_2)$ put

$$
A_r(S) := L_r^2(S) = \left( \sum_{k=1}^{\infty} a_k(S)^r \right)^{1/r}.
$$

A result of Mitjagin which was first published in [12], states that for $2 \leq r < \infty$,

$$
[\mathcal{A}_r(l_2, l_2), A_r] = [\mathcal{P}_r, \mathcal{P}_2(l_2, l_2), \pi_{r, 2}]
$$

(see e.g. [23, 2.11.28]). By use of our tensor multiplicative concept one can even prove the following integral characterization of the Schatten-von Neumann classes.

2.2.1. Theorem. Let $2 \leq r < \infty$, $0 < p \leq 2 < s \leq \infty$ and $\frac{1}{s} + \frac{1}{r} = \frac{1}{2}$. Then $\mathcal{A}_r(l_2, l_2) = \mathcal{M}_{s, p}(l_2, l_2)$, and for every $S \in \mathcal{A}_r(l_2, l_2)$,

$$
A_r(S) \leq \mu_{s, p}(S) \leq \mu_{s, p}(l_2) A_r(S),
$$

i.e., for all probability measures $\mu \in W(B_{l_2})$ there is a probability measure $\nu \in W(B_{l_2})$ such that for all $x \in l_2$

$$
\left( \int |\langle Sx, a \rangle|^s d\mu(a) \right)^{1/s} \leq \mu_{s, p}(l_2) A_r(S) \left( \int |\langle x, a \rangle|^p d\nu(a) \right)^{1/p}.
$$
Proof. As in the proof of 2.1.1 we may restrict our considerations to the case \( p = 2 \). By (the easier part of) Mitjagin’s result

\[
[\mathcal{M}_2(l_2, l_2), \mu_2, 2] \subseteq [\mathcal{P}_2(l_2, l_2), \pi_2, 2] \subseteq [\mathcal{A}_2(l_2, l_2), A_r].
\]

For the converse inclusion we again apply 1.3.2 Lemma. One has

\[
[\mathcal{A}_2(l_2, l_2), A_r] \subseteq \mathcal{L}_r^a(l_2, l_2) = \mathcal{L}_r^a(l_2, l_2)
\]

and by 1.2.1, \( \mathcal{L}_r^a(l_2, l_2) \subseteq \mathcal{M}_2(l_2, l_2) \).

Moreover, 1.4.5(1) and [23, 2.11.22] imply for all \( S \in \mathcal{L}(l_2^n, l_2^n) \)

\[
\mu_2(S)^2 \leq \mu_2(S \otimes S : l_2^n \to l_2^n) \quad A_r(S \otimes S : l_2^n \to l_2^n) = A_r(S)^2,
\]

and hence by 1.3.2 for all \( S \in \mathcal{L}(l_2^n, l_2^n) \), \( \mu_2(S) \leq A_r(S) \).

Using the final argument of the proof of 2.1.1 we get the desired inclusion

\[
[\mathcal{A}_2(l_2, l_2), A_r] \subseteq [\mathcal{M}_2(l_2, l_2), \mu_2, 2].
\]

As a corollary we mention the full statement of Mitjagin’s theorem (with a slightly better norm estimate).

2.2.2. Corollary. Let \( 2 \leq r < \infty \), \( 0 < p \leq 2 \), and \( p \leq q \leq \infty \) with \( \frac{1}{q} = \frac{1}{r} + \frac{1}{p} - \frac{1}{2} \). Then

\[
[\mathcal{A}_r(l_2, l_2) = \mathcal{P}_q, p(l_2, l_2),
\]

and for all \( S \in \mathcal{A}_r(l_2, l_2) \)

\[
A_r(S) \leq \pi_q, p(S) \leq \mu_2, p(l_2) A_r(S).
\]

Proof. Since \( p \leq 2 \), \( q \leq r \) and \( \frac{1}{p} - \frac{1}{q} = \frac{1}{2} - \frac{1}{r} \),

\[
[\mathcal{P}_q, p(l_2, l_2), \pi_q, p] \subseteq [\mathcal{P}_2(l_2, l_2), \pi_2, 2] \subseteq [\mathcal{A}_r(l_2, l_2), A_r].
\]

Conversely: If \( \frac{1}{s} + \frac{1}{q} = \frac{1}{p} \), then \( \frac{1}{s} + \frac{1}{r} = \frac{1}{2} \). Hence by the preceding theorem

\[
[\mathcal{A}_r(l_2, l_2) \subseteq \mathcal{M}_s, p(l_2, l_2) \subseteq \mathcal{P}_q, p(l_2, l_2),
\]

and for all \( S \in \mathcal{A}_r(l_2, l_2) \)

\[
\pi_q, p(S) \leq \mu_s, p(S) \leq \mu_2, p(l_2) A_r(S). \]

\( \square \)

2.3. Identity operators from \( l_u \) into \( l_v \). The following characterization of those identity operators \( I : l_u \to l_v \) \( 1 \leq u \leq v \leq \infty \) which are absolutely \( (r, 2) \)-summing has been determined by Bennett [2] (see also [3]) and the first author [4].

Let \( 1 \leq u \leq 2 \), \( 1 \leq u \leq \infty \), and \( 2 \leq r \leq \infty \). Then \( I \in \mathcal{P}_r, 2(l_u, l_v) \) if \( \frac{1}{r} \leq \frac{1}{u} - \max\{\frac{1}{v}, \frac{1}{2}\} \).

Again this result is sharp in the sense that \( I \notin \mathcal{P}_r, 2(l_u, l_v) \) if \( \frac{1}{r} - \frac{1}{u} + \max\{\frac{1}{v}, \frac{1}{2}\} =: \varepsilon > 0 \). In this case for all \( n \in \mathbb{N} \)

\[
(2.3.1) \quad n^\varepsilon \leq \pi_r, 2(id : l_u^n \to l_v^n)
\]

(see the proofs of [4, Theorems 1 and 2]). Especially the case \( v = 2 \) has proved successful in its application to the theory of distribution of eigenvalues of matrices and integral operators as has been discovered by König, Pietsch, Retherford, and Tomczak-Jaegermann (see [11, 23]).
In this section we reprove and extend this result by use of our tensor product trick within the theory of s-numbers. For this purpose we recall the definition of Hilbert numbers given by Bauhardt [1]. The nth Hilbert number of an operator \( S \in \mathcal{L}(E, F) \) is defined by

\[
h_n(S) := \sup \{ a_n(YSX) \lVert X : l_2 \to E \rVert \leq 1, \lVert Y : F \to l_2 \rVert \leq 1 \}.
\]

We start with a result which is implicitly found in [21].

2.3.2. Lemma.

(1) Let \( S \in \mathcal{L}(E, F) \) with \( \dim E = \dim F = \text{rank} S = n \). Then for all \( 1 \leq k \leq n \), \( h_k(S)a_{n-k+1}(S^{-1}) \leq 1 \).

(2) Let \( S \in \mathcal{L}(E, l_2^n) \) with \( \dim E = \text{rank} S = n \). Then for all \( 1 \leq k \leq n \), \( x_k(S)a_{n-k+1}(S^{-1}) = 1 \).

Proof. (1) Let \( 0 < \varepsilon < 1 \) and \( 1 \leq k \leq n \). By Bauhardt's characterization [1] of Hilbert numbers (see also [22, 11.4.3]) there are operators \( X \in \mathcal{L}(l_2^n, E) \) and \( Y \in \mathcal{L}(F, l_2^n) \) such that \( \lVert X \rVert \leq 1, \lVert Y \rVert \leq 1 \), and \((1-\varepsilon)h_k(S)\text{id} = YSX\).

Put \( \rho := (1-\varepsilon)h_k(S) \) and \( A := S^{-1} - \rho^{-1}XY \). Since \( ASX = 0 \) we have

\[
\dim \text{kern } A \geq \text{rank } SX = k > k - 1
\]

(note that \( SX \) is injective), and in particular

\[
\text{rank } A = n - \dim \text{kern } A < n - k + 1.
\]

Consequently, the conclusion follows by

\[
(1-\varepsilon)h_k(S)a_{n-k+1}(S^{-1}) \leq \rho \lVert S^{-1} - A \rVert \leq \lVert X \rVert \lVert Y \rVert \leq 1.
\]

(2) By (1) the inequality \( \leq \) is clear, since \( x_k(S) = h_k(S) \). On the other hand

\[
1 = x_n(\text{id} : l_2^n \to l_2^n)
\]

\[
\leq x_k(S : E \to l_2^n)x_{n-k+1}(S^{-1} : l_2^n \to E)
\]

\[
= x_k(S : E \to l_2^n)a_{n-k+1}(S^{-1} : l_2^n \to E).
\]

As a consequence we prove

2.3.3. Proposition. Let \( 1 \leq u \leq 2 \) and \( 1 \leq u \leq v \leq \infty \). Then for all \( 1 \leq k \leq n \)

(1) \( x_k(\text{id} : l_u^n \to l_2^n) = k^{1/2-1/u} \).  

(2) \( x_k(\text{id} : l_u^n \to l_2^n) \leq k^{\max(1/v, 1/2) - 1/u} \).

Proof. Since by a result of Pietsch [23, 2.9.8] for \( 1 \leq u \leq 2 \) and \( 1 \leq k \leq n \), \( a_{n-k+1}(\text{id} : l_2^n \to l_u^n) = k^{1/u-u/2} \), the preceding lemma proves (1).

Let us now prove (2). If \( 1 \leq u \leq 2 \leq v \leq \infty \) then for all \( 1 \leq k \leq n \)

\[
x_k(\text{id} : l_u^n \to l_v^n) \leq x_k(\text{id} : l_u^n \to l_2^n) = k^{1/2-1/u}.
\]

The case \( 1 \leq u \leq v < 2 \) follows by interpolation: Define

\[
\theta := \frac{1/u - 1/v}{1/u - 1/2},
\]

so that \( \frac{1}{v} = \frac{\theta}{2} + \frac{1-\theta}{u} \), and let \( A \in \mathcal{L}(l_2, l_u^n) \) with \( \lVert A \rVert \leq 1 \). Then by Hölder's inequality for \( x \in l_2 \)

\[
l_v(Ax) \leq l_2(Ax)^\theta l_u(Ax)^{1-\theta}.
\]
Hence for each subspace $M$ of $l_2$ we conclude with the natural embedding $I_M^{l_2}$ from $M$ into $l_2$

$$
\|AI_M^{l_2} : M \to l_2^n\| \leq \|AI_M^{l_2} : M \to l_2^n\|^{1-\theta} \leq \|AI_M^{l_2} : M \to l_2^n\|^{1-\theta},
$$
and consequently for all $1 \leq k \leq n$

$$
a_k(A : l_2 \to l_2^n) \leq a_k(A : l_2 \to l_2^n)^{\theta}
$$
(Obviously the latter inequality holds for the so-called Gelfand numbers which for operators defined on $l_2$ coincide with the approximation numbers, see [11 or 23]). Finally, we get for all $1 \leq k \leq n$

$$
x_k(id : l_u^n \to l_v^n) \leq x_k(id : l_u^n \to l_v^n)^{\theta} = k^{(1/2-1/u)\theta} = k^{1/v-1/u}.
$$

We are now prepared to state the following abstract version of the characterization of absolutely $(r, 2)$-summing identity operators $I : l_u \to l_v$ mentioned at the beginning of this section.

**2.3.4. Lemma.** Let $1 \leq u \leq 2$, $1 \leq u \leq v \leq \infty$, and $2 \leq r < \infty$. Let $[\mathcal{A}, A]$ be a quasi-Banach ideal such that

$$
\mathcal{L}_r,1(l_u, l_v) \subseteq \mathcal{A}(l_u, l_v) \subseteq \mathcal{L}_r,\infty(l_u, l_v).
$$

Moreover, assume that there is a constant $a \geq 1$ with

$$
A(id : l_u^n \to l_v^n) \leq a A(id : l_u^n \to l_v^n)
$$
for all $n \in \mathbb{N}$. Then the following alternative holds:

1. If $\frac{1}{r} \leq \frac{1}{u} - \max\{\frac{1}{v}, \frac{1}{2}\}$, then $\sup_{n \in \mathbb{N}} A(id : l_u^n \to l_v^n) \leq a$.
2. If $\frac{1}{r} - \frac{1}{u} + \max\{\frac{1}{v}, \frac{1}{2}\} =: \epsilon > 0$, then $n^\epsilon \leq A(id : l_u^n \to l_v^n)$ for large $n$.\]

**Proof.** (1) We denote by $\mathcal{E}$ the tensor stable set for all identity operators $id : \mathbb{K}^n \to \mathbb{K}^n$, where $n \in \mathbb{N}$. Then by assumption $A : id \leadsto A(id : l_u^n \to l_v^n)$ is an $a$-tensor supermultiplicative function on $\mathcal{E}$ and

$$
\| \cdot \| : id \leadsto \| id : l_u^n \to l_v^n \|
$$
is obviously a $1$-tensor submultiplicative function on $\mathcal{E}$. Moreover, by the closed graph theorem and the preceding proposition there is a constant $c \geq 1$ such that for all $n \in \mathbb{N}$

$$
A(id : l_u^n \to l_v^n) \leq c L_{r,1}^x(id : l_u^n \to l_v^n)
$$

$$
= c \sum_{k=1}^n k^{1/r-1} x_k(id : l_u^n \to l_v^n)
$$

$$
= c \sum_{k=1}^n k^{1/r-1+\max\{1/v, 1/2\}-1/u}
$$

$$
\leq c (1 + \log n) \| id : l_u^n \to l_v^n \|.
$$

But then the desired inequality follows from 1.3.1.

(2) There is $\delta_0 > 0$ such that for all $0 < \delta < \delta_0$

$$
\epsilon_\delta := \frac{1}{r + \delta} - \frac{1}{u} + \max\{\frac{1}{v}, \frac{1}{2}\} > 0.
$$
Moreover, there is a (uniform) constant $c > 1$ such that for all $0 < \delta < \delta_0$ and $n \in \mathbb{N}$
\[ \pi_{r+\delta,2}(id : l^n_u \to l^n_v) \leq c L^x_{r+\delta,1}(id : l^n_u \to l^n_v) \]
(see e.g. the proofs of [11, 1.d.20 and 2.a.11]). Hence by assumption and (2.3.1) there is $d \geq 1$ such that for all $0 < \delta < \delta_0$ and $n \in \mathbb{N}$
\[ n^{\delta} \leq c L^x_{r+\delta,1}(id : l^n_u \to l^n_v) \leq c L^x_{r,\infty}(id : l^n_u \to l^n_v) \leq c \ell (id : l^n_u \to l^n_v). \]
Finally if $\delta$ tends to 0 for each fixed $n$, we obtain (2). □

An almost immediate consequence of this lemma is the following main result of this section.

2.3.5. Theorem. Let $1 \leq u \leq 2$, $1 \leq u \leq v \leq \infty$ and $0 < p \leq 2 \leq s \leq \infty$.

(1) If $\frac{1}{s} \geq \frac{1}{r} - \frac{1}{u} + \max\{\frac{1}{s}, \frac{1}{2}\}$, then $I \in \mathcal{M}_{s,p}(l_u, l_v)$ and
\[ \mu_{s,p}(I : l_u \to l_v) \leq \mu_{2,p}(l_u, l_v). \]
(2) If $\frac{1}{s} \geq \frac{1}{r} - \frac{1}{u} + \max\{\frac{1}{s}, \frac{1}{2}\} - \frac{1}{s} = \varepsilon > 0$, then $I \notin \mathcal{M}_{s,p}(l_u, l_v)$ and
\[ n^{\varepsilon} \leq \mu_{s,p}(id : l^n_u \to l^n_v), \text{ for all } n \in \mathbb{N}. \]

Proof. In order to prove (1) we first observe the following. Exactly as in the proof of Theorem 2.1.1 it is enough to show that in the case $p = 2$ for all $n \in \mathbb{N}, \mu_{s,2}(id : l^n_u \to l^n_v) \leq \mu_{2,u}(l_2)$.

Since by 1.2.1
\[ L^x_{r,1} \subseteq \mathcal{M}_{s,2} \subseteq L^x_{r,\infty}, \quad \frac{1}{s} + \frac{1}{r} = \frac{1}{2}, \]
and by 1.4.5(2) for all $n \in \mathbb{N}$
\[ \mu_{s,2}(id : l^n_u \to l^n_v)^2 \leq \mu_{2,u}(l_2) \mu_{s,2}(id : l^n_u \to l^n_v), \]
we just apply the preceding lemma.

Finally we prove (2). By (2.3.1) we know that for all $n \in \mathbb{N}$
\[ n^{\varepsilon} \leq \pi_{r,2}(id : l^n_u \to l^n_v) \leq \mu_{s,2}(id : l^n_u \to l^n_v), \quad \frac{1}{s} + \frac{1}{r} = \frac{1}{2}. \]
Since $[\mathcal{M}_{s,p}, \mu_{s,p}] \subseteq [\mathcal{M}_{s,2}, \mu_{s,2}]$ this implies the desired result. □

Let us again give a second more analytic formulation of part (1): If $1 \leq u \leq 2$, $1 \leq u \leq v < \infty$, $0 < p \leq 2 \leq s < \infty$, and $\frac{1}{s} \geq \frac{1}{r} - \frac{1}{u} + \max\{\frac{1}{s}, \frac{1}{2}\}$, then for every probability measure $\mu \in W(B_{l_u})$ there is a probability measure $\nu \in W(B_{l_v})$ such that for all $x \in l_u$
\[ \left( \int |\langle x, a \rangle|^s d\mu(a) \right)^{1/s} \leq \mu_{2,p}(l_u, l_v) \left( \int |\langle x, a \rangle|^p d\nu(a) \right)^{1/p}. \]
In particular, we reproved the characterization of absolutely $(r, 2)$-summing identity operators $I : l_u \to l_v$ (with new estimates for the norms). The full statement is
2.3.6. Corollary. Let $1 \leq u \leq 2$, $1 \leq u \leq v \leq \infty$, $0 < p \leq 2$, and $0 < p \leq r \leq \infty$.

(1) If $\frac{1}{r} \leq \frac{1}{p} - \frac{1}{2} + \frac{1}{u} - \max\{\frac{1}{v}, \frac{1}{2}\}$, then $I \in R_{r,p}(l_u, l_v)$ and $\pi_{r,p}(I) \leq \mu_{2,p}(l_u)\mu_{2,u}(l_2)$.

(2) If $\frac{1}{r} - \frac{1}{p} - \frac{1}{2} - \frac{1}{u} + \max\{\frac{1}{v}, \frac{1}{2}\} =: \epsilon > 0$, then $I \notin R_{r,p}(l_u, l_v)$ and $\pi_{r,p}(I) \leq \pi_{r,p}(\text{id} : l_u^n \to l_v^n)$ for all $n \in \mathbb{N}$.

Proof. Since $[M_{s,p}, \mu_{s,p}] \subseteq [R_{r,p}, \pi_{r,p}]$ for $\frac{1}{s} + \frac{1}{r} = \frac{1}{p}$, statement (1) is a consequence of part (1) of the theorem. Part (2) is again an easy consequence of (2.3.1). □

We finish this section with the following remark:

For $1 \leq p, q \leq \infty$ let $A$ be a continuous bilinear form on $l_p \times l_q$. Then

$$\left(\sum_{i=1}^{\infty} \left(\sum_{j=1}^{\infty} |A(e_i, e_j)|^v\right)^{r/v}\right)^{1/r} \leq \mu_{2,p'}(l_{q'})\mu_{2,q'}(l_2)\|A\|,$$

if $1 \leq p', q' \leq 2$, $1 \leq p' \leq r \leq \infty$, $1 \leq q' \leq v \leq \infty$ and $\frac{1}{r} + \max\{\frac{1}{v}, \frac{1}{2}\} = \frac{3}{2} - \frac{1}{p'} - \frac{1}{q'}$.

This comprises and extends the main results of Hardy and Littlewood’s paper [10]. By the last corollary the proof is easy: if $\hat{A} : l_p \to l_{q'}$ is the linear operator corresponding to the bilinear form $A$, then $I\hat{A} : l_p \to l_{q'} \hookrightarrow l_v$ is absolutely $(r, p')$-summing and

$$\pi_{r,p'}(I\hat{A}) \leq \mu_{2,p'}(l_{q'})\mu_{2,q'}(l_2)\|A\|,$$

since $\frac{1}{r} = \frac{1}{p'} - \frac{1}{2} + \frac{1}{q'} - \max\{\frac{1}{v}, \frac{1}{2}\}$. Hence

$$\left(\sum_{i=1}^{\infty} |l_v(\hat{A}e_i)|^r\right)^{1/r} \leq \pi_{r,p'}(I\hat{A})\omega_{p'}(e_i ; l_p) \leq \mu_{2,p'}(l_{q'})\mu_{2,q'}(l_2)\|A\|.$$
