ON THE NUMBER OF $L_{\infty_1}$-EQUIVALENT NON-ISOMORPHIC MODELS

SAHARON SHELAH AND PAULI VÄISÄNEN

Abstract. We prove that if ZF is consistent then ZFC + GCH is consistent with the following statement: There is for every $k < \omega$ a model of cardinality $\aleph_1$ which is $L_{\infty_1}$-equivalent to exactly $k$ non-isomorphic models of cardinality $\aleph_1$. In order to get this result we introduce ladder systems and colourings different from the “standard” counterparts, and prove the following purely combinatorial result: For each prime number $p$ and positive integer $m$ it is consistent with ZFC + GHC that there is a “good” ladder system having exactly $p^m$ pairwise nonequivalent colourings.

1. Introduction

If $M$ is a model, $\text{card}(M)$ denotes the cardinality of the universe of $M$. Suppose $M$ and $N$ are two models of the same vocabulary and $\kappa$ is a cardinal. We write $M \equiv_{\kappa} N$ if $M$ and $N$ satisfy the same sentences of the infinitary language $L_{\infty, \kappa}$. For a definition of $L_{\infty, \kappa}$, the reader is referred to [Dic85]. For any model $M$ of cardinality $\kappa$, define

$$\text{No}(M) = \text{card}\left(\{N/\cong \mid \text{card}(N) = \kappa \land N \equiv_{\infty, \kappa} M\}\right),$$

where $N/\cong$ is the equivalence class of $N$ under the isomorphism relation. We study the possible values of $\text{No}(M)$ for models $M$ of cardinality $\aleph_1$. In particular, we prove the following theorem:

Theorem 1. Assuming ZF is consistent, it is consistent with ZFC + GCH that there is for every $k < \omega$ a model $M$ (of a vocabulary of cardinality $\leq \aleph_1$) such that $\text{card}(M) = \aleph_1$ and $\text{No}(M) = k$.

When $M$ is countable, $\text{No}(M) = 1$ by [Sco65]. This result extends to structures of cardinality $\kappa$ when $\kappa$ is a singular cardinal of countable cofinality [Cha68]. So the study of possible values of $\text{No}(M)$ is divided into the following cases according
to the cardinality of $M$:

1) $\text{card}(M)$ is weakly compact;
2) $\text{card}(M)$ is singular of uncountable cofinality;
3) $\text{card}(M)$ is uncountable, regular, and non-weakly compact.

In [She82a] Shelah was able to show that when $\kappa$ is a weakly compact cardinal there is for every non-zero cardinal $\mu \leq \kappa$, a model $M$ such that $\text{card}(M) = \kappa$ and $\text{No}(M) = \mu$. In a paper which is in preparation by the authors, the problem of the possible value of $\text{No}(M)$ between $\kappa$ and $2^\kappa$ for a model $M$ of weakly compact cardinality is completely solved.

Shelah has considered the singular case in two of his papers [She85], [She86]. Let $\kappa$ be a singular cardinal of uncountable cofinality. In the former paper it is shown that if one allows relation symbols of arbitrarily large arity $< \kappa$ and $\mu$ is a non-zero cardinal with $\mu^{\text{cf}(\kappa)} < \kappa$, then there exists a model $M$ of singular cardinality $\kappa$ with $\text{No}(M) = \mu$. In the latter paper Shelah gives a general way to build models $M$ with relations of finite arity only and for which the value of $\text{No}(M)$ is quite arbitrary: for every non-zero cardinal $\mu \in \kappa \cup \{\kappa^{\text{cf}(\kappa)}\}$, there exists a model $M$ of cardinality $\kappa$ such that $\text{No}(M) = \mu$ and its vocabulary consists of one binary relation symbol, provided that $\theta^{\text{cf}(\kappa)} < \kappa$ for all $\theta < \kappa$. The paper [She86] together with the recent paper [SV] offers a complete answer to the singular case provided that the singular cardinal hypothesis holds. For example, it follows that $\text{No}(M) = \kappa$ is possible, even in $L$.

If $V = L$ and $\kappa \geq \aleph_1$ is a regular cardinal which is not weakly compact, $\text{No}(M)$ has value either $1$ or $2^\kappa$ for all models $M$ having cardinality $\kappa$. For $\kappa = \aleph_1$ this result was first proved in [Pai77a]. Later Shelah extended the result to all other regular non-weakly compact cardinals in [She81b].

It seems that there are no published independence results about the case that $\text{card}(M)$ is a regular but not weakly compact cardinal. But it is known that the independence result given in [She81a] implies the consistency of “there is a model $M$ of cardinality $\aleph_1$ such that $\text{No}(M) = \aleph_0$” with ZFC+ GCH. Namely, in $\text{She81a}$ Shelah proves it is consistent with ZFC+ GCH that there is a group $G$ for which the group of extensions of $\mathbb{Z}$ by $G$, in symbols $\text{Ext}(G, \mathbb{Z})$, is the additive group of rationals. Here $\mathbb{Z}$ is the additive group of integers. Then one extension of $\mathbb{Z}$ by $G$ can be directly coded to a model $M$ such that $\text{No}(M) = \text{card}(\text{Ext}(G, \mathbb{Z})) = \aleph_0$. The $L_{\omega_1}$-equivalence between two coded models follows from the group theoretic properties of $G$ ($G$ is strongly $\aleph_1$-free). But $\text{Ext}(G, \mathbb{Z})$ is a divisible group, and hence this coding mechanism is not applicable to the case $1 < \text{No}(M) < \aleph_0$. So it remained unknown whether it is consistent to have a model $M$ of cardinality $\aleph_1$, for which $1 < \text{No}(M) < \aleph_0$.

As Shelah did with the Whitehead problem, we transform Theorem 1 into a question of the nature of pure combinatorial set theory. The combinatorial problem will be a variant of the uniformization principles and ladder systems given for example in [She82b] or [EM90]. As a matter of fact, the more complicated ladder systems used here trace back to the papers [She80] and [She81a].

For the benefit of the reader we sketch the “standard” notion of $(\eta, 2)$-uniformization. For a limit ordinal $\delta < \omega_1$, a ladder on $\delta$ is a strictly increasing $\omega$-sequence of ordinals with limit $\delta$. Let $S$ be a set of limit ordinals below $\omega_1$. A ladder system on $S$ is a function $\eta : S \rightarrow {}^\omega \omega_1$ such that each $\eta(\delta)$ is a ladder on $\delta$. A 2-colouring on $S$ is a function $c : S \rightarrow {}^n \{0, 1\}$. For all $\delta \in S$ and $n < \omega$, a 2-colouring $c$ on
\( S \) associates the element \( c_{\delta,n} \) (the \((n + 1)\)th element of the sequence \( c(\delta) \)) to each "step" \( \eta_{\delta,n} \) of a ladder system \( \eta \) on \( S \), hence the name 2-colouring. A 2-colouring \( c \) on \( S \) can be uniformized if there is a function \( f : \omega_1 \rightarrow \{0, 1\} \) satisfying the condition that for all \( \delta \in S \) there is \( m < \omega \) such that for all \( n < \omega, n > m \) implies \( f(\eta_{\delta,n}) = c_{\delta,n} \). Such a function \( f \) is called a uniformizing function, and we say that \( c \) is uniform with respect to \( \eta \). The \((\eta, 2)\)-uniformization holds if every 2-colouring on \( S \) is uniform w.r.t. \( \eta \).

For our purpose we need a different kind of ladder system. The main difference is that instead of the principle "all colourings are uniform" we want to know what the "number of nonuniform colourings" can be. We consider colourings which take values in a field, and hence we can define a natural equivalence relation for colourings. (The following definition is from [She80]; see also [ES96], where colourings which take values in a group are considered.) For 2-colourings \( c \) and \( d \) on \( S \) let \( c - d \) be the 2-colouring \( e \) on \( S \) defined for all \( \delta \in S \) and \( n < \omega \) by \( c_{\delta,n} \in \{0, 1\} \) and \((e_{\delta,n} + d_{\delta,n}) \equiv c_{\delta,n} \pmod{2}\). Then 2-colourings \( c \) and \( d \) on \( S \) are equivalent w.r.t. a ladder system \( \eta \) on \( S \) if \( c - d \) is uniform w.r.t. \( \eta \). The number of pairwise nonequivalent colourings is the number of equivalence classes of 2-colourings on \( S \) under the given equivalence relation. But as it is pointed out in [She80, Theorem 6.2], for any set \( S \in \omega_1 \) of limit ordinals and any ladder systems on \( S \), the number of pairwise nonequivalent colourings is either 1 or \( 2^{\aleph_0} \). In our transformation of Theorem 1 the value of \( \text{No}(M) \) will correspond to the number of pairwise nonequivalent colourings. So, all the cases \( 1 < \text{No}(M) \leq \aleph_0 \) are ruled out when only standard ladder systems are considered.

The main result on the combinatorial problem is that, for all finite fields \( F \),

it is consistent with ZFC+ GCH that there are "good" ladder system and a "good" equivalence for colourings (which take values in \( F \)) such that the number of pairwise nonequivalent colourings is \( \text{card}(F) \).

Recall that all finite fields are of the size \( p^m \) with \( p \) a prime number and \( m \) a positive integer.

In standard ladders each step is one ordinal. The principal idea of the "good" ladders will be to answer the following simple question: what happens if each step could be a finite set of ordinals, or even a "linear combination" of standard steps?

In order to make our presentation self contained we give proofs of some facts which are essentially proved elsewhere (mainly in [She77] and [She81a]). In Subsection 2.1 we give the exact definitions for the "good" ladder systems, colourings, and equivalence. In Subsection 2.2 we introduce some basic facts about iterated forcing.

In Section 3 the combinatorial problem is reformulated in a precise form, and a solution of the problem is presented. Some remarks concerning generalizations are given in Subsection 3.3. Since ladder systems and uniformization principles are also used in abelian group theory and general topology, this section may be of independent interest.

Section 4 is devoted to the proof of Theorem 1. We take a "good" ladder system and code each colouring \( a \) to a model \( M_a \). Then all of the coded models will be \( L_{\omega_1} \)-equivalent, and moreover, they are isomorphic if and only if the corresponding colourings are equivalent. So the main result really is a straightforward consequence of the independence result concerning the combinatorial problem. The coding technique we have used in the proof of Theorem 1 is a nice trick, and may
also be of independent interest. Hence Section 4 is written in a way that if the reader accepts Theorem 2 on faith, she or he can read only Subsection 2.1 and then proceed directly to Section 4.

2. Preliminaries

For all sets $X, Y, Z$, ordinals $\alpha$ and functions $f : X \to Y$:

- the restriction $f|Z$ has the meaning $f|(Z \cap \text{dom}(f))$,
- $X^Y$ is the set of all functions from $X$ into $Y$,
- $^\alpha Y$ is the set of all $\alpha$-sequences of elements in $Y$, and $^{<\alpha} Y = \bigcup_{\beta < \alpha} \beta Y$.

Let $S$ be a subset of a limit ordinal $\mu$ with uncountable cofinality. The set $S$ is stationary in $\mu$ if for all closed unbounded subsets $C$ of $\mu$, $S \cap C$ is nonempty. The set $S$ is bistationary in $\mu$ if $S$ and $\mu \setminus S$ are both stationary in $\mu$.

2.1. Ladder Systems and Colourings. Suppose $\langle F, +, \cdot, 0, 1 \rangle$ is a field. We denote by $\text{Vec}_F$ the vector space over $F$ freely generated by $\langle x_\xi \mid \xi < \omega_1 \rangle$. Suppose $y$ is an element of $\text{Vec}_F$ and $\epsilon_\xi \in F$ are coefficients such that
\[ y = \sum_{\xi < \omega_1} \epsilon_\xi x_\xi, \]
where only finitely many of the coefficients are nonzero. The support of $y$, in symbols $\text{supp}(y)$, is the set $\{ \xi < \omega_1 \mid \epsilon_\xi \neq 0 \}$. For all functions $f : \mu \to F$ such that $\text{supp}(y) \subseteq \mu \leq \omega_1$, $f(y)$ is a shorthand for the following element of $F$:
\[ \sum_{\xi < \omega_1} \epsilon_\xi \cdot f(\xi). \]

A subset $Y$ of $\text{Vec}_F$ is unbounded if for all $\theta < \omega_1$ there is some $y \in Y$ for which $\theta < \min(\text{supp}(y))$.

**Definition 2.1.**

a) A $\text{Vec}_F$-ladder on $\delta$, where $\delta < \omega_1$ is a limit ordinal, is a sequence $\langle y_n \mid n < \omega \rangle$ of elements in $\text{Vec}_F$ such that
\[ i) \bigcup_{n < \omega} \text{supp}(y_n) \subseteq \delta, \]
\[ ii) \langle \min(\text{supp}(y_n)) \mid n < \omega \rangle \text{ is an increasing sequence of ordinals with limit } \delta, \]
\[ iii) \text{ for all } n < \omega, \text{ supp}(y_n) \not\subseteq \bigcup_{m < n} \text{supp}(y_m). \]

b) A $\text{Vec}_F$-ladder system on $S$, where $S$ is a set of limit ordinals below $\omega_1$, is a function $\mathbf{x}$ from $S$ into $\text{Vec}_F$-ladders such that for each $\delta \in S$, $\mathbf{x}(\delta)$ is a $\text{Vec}_F$-ladder on $\delta$.

c) An $F$-colouring on $S$ is a function from $S$ into $\omega F$. The set of all such colourings is $\text{Col}_{S,F}$.

For all $\delta \in S$ and $\text{Vec}_F$-ladder systems $\mathbf{x}$ on $S$:

- the $(n + 1)$th element in the $\omega$-sequence $\mathbf{x}(\delta)$ is denoted by $\mathbf{x}_{\delta,n}$;
- $\text{supp}(\mathbf{x}(\delta))$ is a shorthand for $\bigcup_{n < \omega} \text{supp}(\mathbf{x}_{\delta,n})$;
- for a function $f$ with $\text{supp}(\mathbf{x}(\delta)) \subseteq \text{dom}(f)$ and $\text{ran}(f) \subseteq F$, $f(\mathbf{x}(\delta))$ is a shorthand for the sequence $\langle f(\mathbf{x}_{\delta,n}) \mid n < \omega \rangle$.

When $f$ is a function with $\text{dom}(f) = \omega_1$ and $\text{ran}(f) \subseteq F$, $f(\mathbf{x})$ denotes the function from $S$ into $\omega F$ which maps each $\delta \in S$ into $f(\mathbf{x}(\delta))$. 
Definition 2.2. Suppose $x$ is a Vec$_F$-ladder system on $S$, $a \in \text{Col}_{S,F}$, and $D$ is a filter over $\omega$ including all cofinite subsets of $\omega$, i.e., all subsets $I$ of $\omega$ for which $\omega \setminus I$ is finite.

a) If $\delta \in S$ and $f$ is a function with $\text{supp}(x(\delta)) \subseteq \text{dom}(f) \subseteq \omega_1$ and $\text{ran}(f) \subseteq F$, then $f(x_\delta, n) = a_\delta, n$ for almost all $n < \omega$, or in symbols $f(x(\delta)) \eqrel_D a(\delta)$, when

$$\{ n < \omega \mid f(x_\delta, n) = a_\delta, n \} \in D.$$ 

b) If $f$ is a function with $\mu \subseteq \text{dom}(f)$ and $\text{ran}(f) \subseteq F$, then $f$ uniformizes $a|_\mu + 1$ with respect to $x$ and $D$, when $f(x(\delta)) \eqrel_D a(\delta)$ for all $\delta \in S \setminus \mu + 1$.

c) An $F$-colouring $a$ on $S$ is uniform w.r.t. $x$ and $D$ if there is $f : \omega_1 \to F$ satisfying $f(x(\delta)) \eqrel_D a(\delta)$ for all $\delta \in S$. The set of all uniform $F$-colourings on $S$ w.r.t. $x$ and $D$ is $\text{Unif}_{x,D}$.

d) The set $\text{Col}_{S,F}$ forms a vector space over the field $F$ when addition in $\text{Col}_{S,F}$ and operation of $F$ on $\text{Col}_{S,F}$ are defined componentwise, and the unit element for addition is the function which is constantly $0$. Using the addition of this space, we define $a$ and $b$ in $\text{Col}_{S,F}$ to be equivalent w.r.t. $x$ and $D$, written $a \sim_{x,D} b$, if $a - b$ is a uniform colouring w.r.t. $x$ and $D$. We denote by $\langle a \rangle_F$ the subspace of $\text{Col}_{S,F}$ generated by $a \in \text{Col}_{S,F}$.

It is easy to see that the set $\text{Unif}_{x,D}$ forms a subspace of $\text{Col}_{S,F}$. So the factor space $\text{Col}_{S,F}/\text{Unif}_{x,D}$ also forms a vector space over $F$, and consequently, for all $a, b \in \text{Col}_{S,F}$, $a \sim_{x,D} b$ if and only if $a$ and $b$ belong to the same coset of $\text{Col}_{S,F}/\text{Unif}_{x,D}$. If $A$ and $C$ are subsets of $\text{Col}_{S,F}$ then $A + C$ is $\{ a + c \mid a \in A \& c \in C \}$. Hence $\langle b \rangle_F + \text{Unif}_{x,D}$ denotes the set

$$\{ a + c \mid a \in \langle b \rangle_F \& c \in \text{Unif}_{x,D} \} = \{ (e \cdot b) + c \mid e \in F \& c \in \text{Unif}_{x,D} \} = \{ d \in \text{Col}_{S,F} \mid \text{there is } e \in F \text{ such that } e \cdot b \sim_{x,D} d \}.$$ 

Lemma 2.3. Suppose $D$ is a filter over $\omega$ including all cofinite sets of $\omega$, $S \subseteq \omega_1$ is a set of limit ordinals, $F$ is a field, and $x$ is a Vec$_F$-ladder system on $S$.

a) If $a$ is an $F$-colouring on $S$, $\mu_0 \subseteq \omega_1$, and $f_0 : \mu_0 \to F$ uniformizes $a|_{\mu_0 + 1}$ w.r.t. $x$ and $D$, then for all $\mu_1 \subseteq \omega_1 \setminus (\mu_0 + 1)$, there is an extension $f_1 : \mu_1 \to F$ of $f_0$ which uniformizes $a|(\mu_1 + 1)$ w.r.t. $x$ and $D$.

b) If $S$ is nonstationary in $\omega_1$, then all $F$-colourings on $S$ are uniform w.r.t. $x$ and $D$.

c) Let $a$ be an $F$-colouring on $S$ and $g$ a function from $\omega_1$ into $F$. If there exists $\mu \subset \omega_1$ such that $g(x(\delta)) \eqrel_D a(\delta)$ for all $\delta \in S \setminus \mu$, then $a$ is uniform w.r.t. $x$ and $D$.

Proof. Suppose $S$ is enumerated by $\{ \delta_\alpha \mid \alpha < \omega_1 \}$, where $\delta_\alpha < \delta_\beta$ for all $\alpha < \beta < \omega_1$, and $e_\alpha^n \in F$, for $\xi, \alpha < \omega_1$ and $n < \omega$, are coefficients such that

$$x_{\delta_\alpha, n} = \sum_{\xi < \delta_\alpha} e^{\alpha, n}_\xi x_\xi.$$ 

Our first task is to find a function $g_\alpha : \text{supp}(x(\delta_\alpha)) \to F$, for all $\alpha < \omega_1$, such that the equation $g_\alpha(x_{\delta_\alpha, n}) = \sum_{\xi < \delta_\alpha} e^{\alpha, n}_\xi \cdot g_\alpha(\xi) = a_{\delta_\alpha, n}$ holds for all $n < \omega$. Hence
consider the following system of equations:

(A) \[ \text{for all } n < \omega, \quad \sum_{\xi < \delta_n} \alpha_n^\xi \cdot g_\alpha(\xi) = a_{\delta_n,n}. \]

By Definition 4.2 in [III], the set \( \text{supp}(x_{\delta_n,n}) \setminus \bigcup_{m < \omega} \text{supp}(x_{\delta_m,m}) \) is nonempty for all \( n < \omega \). Besides, \( F \) is a field. Thus it is possible to define directly by induction on \( n < \omega \) a solution \( g_\alpha : \text{supp}(x_{\delta_n,n}) \rightarrow F \) for the system of equations (A).

We prove the following claim by induction on \( \alpha < \omega_1 \):

for all \( \mu_0 < \delta_\alpha \) and \( f_0 : \mu_0 \rightarrow F \) uniformizing \( a|\mu_0 + 1 \), there is \( f_1 : \delta_\alpha \rightarrow F \) uniformizing \( a|\delta_\alpha + 1 \) and satisfying \( f_0 \subseteq f_1 \).

Suppose \( \mu_0 = 0 \) and \( \alpha = 0 \). Then \( f_1 = g_0 \cup \{ (\xi, 0) \mid \xi \in \delta_0 \setminus \text{dom}(g_0) \} \) satisfies the claim.

Suppose \( \alpha = \beta + 1 \), \( \mu_0 < \delta_\alpha \), and \( f_0 : \mu_0 \rightarrow F \) uniformizes \( a|\mu_0 + 1 \). Let \( g_\alpha \) be a solution for the system of equations (A). We may assume \( \mu_0 \geq \delta_\beta \), since if not, then the induction hypothesis there is \( f'_0 : \delta_\beta \rightarrow F \) extending \( f_0 \) and uniformizing \( a|\delta_\beta + 1 \). It suffices to prove the claim for such \( f'_0 \).

Define a function \( f_1 : \delta_\alpha \rightarrow F \), for all \( \xi < \delta_\alpha \), by

(B) \[ f_1(\xi) = \begin{cases} f_0(\xi) & \text{if } \xi \in \mu_0 = \text{dom}(f_0); \\ g_\alpha(\xi) & \text{if } \xi \in \text{dom}(g_\alpha) \setminus \mu_0; \\ 0 & \text{otherwise}. \end{cases} \]

Then of course \( f_0 \subseteq f_1 \), and for all \( \delta \in S \setminus \delta_\alpha = (S \setminus \mu_0) \cup \{ \delta_\beta \} \), \( f_1(x(\delta)) = f_0(x(\delta)) = a(\delta) \). By Definition 4.2 in [III], \( \{ n < \omega \mid \text{supp}(x_{\delta_n,n}) \cap \text{supp}(x_{\delta_n,n}) \neq \emptyset \} \) must be finite. Therefore also \( f_1(x(\delta_\alpha)) = g_\alpha(x(\delta_\alpha)) = a(\delta_\alpha) \) holds. So \( f_1 \) uniformizes \( a|\delta_\alpha + 1 \).

Suppose then that \( \alpha \) is a limit ordinal. If the limit sup\( (S \setminus \delta_\alpha) = \theta \) is smaller than \( \delta_\alpha \), i.e., \( \delta_\alpha \) is not a limit of its predecessors in \( S \), then we may assume \( \mu_0 = \text{dom}(f_0) \geq \theta \) by the induction hypothesis. Furthermore, the function \( f_1 \) given in (B), this time for different \( \alpha \) of course, is a uniformizing function for \( a|\delta_\alpha + 1 \).

Suppose \( \delta_\alpha \) is a limit point in \( S \), i.e., \( \theta = \delta_\alpha \). Let \( \{ \epsilon_m \mid m < \omega \} \) be an increasing sequence of ordinals in \( S \) with limit \( \delta_\alpha \). By the induction hypothesis there are for all \( m < \omega \) functions \( h_m : \epsilon_m \rightarrow F \) uniformizing \( a|\epsilon_m + 1 \) and satisfying \( h_m \in h_{m+1} \). This time we may assume \( \text{dom}(f_0) = \mu_0 = \epsilon_0 \) and \( f_0 = h_0 \). Define a function \( f_1 : \delta_\alpha \rightarrow F \), for all \( \xi < \delta_\alpha \), by

\[ f_1(\xi) = \begin{cases} f_0(\xi) & \text{if } \xi < \epsilon_0 = \mu_0 = \text{dom}(f_0); \\ g_\alpha(\xi) & \text{if } \xi \in \text{dom}(g_\alpha) \setminus \text{dom}(f_0); \\ h_l(\xi) & \text{otherwise, where } l = \min \{ m < \omega \mid \xi < \epsilon_m = \text{dom}(h_m) \}. \end{cases} \]

In the definition above, \( g_\alpha \) is a solution for (B). Clearly \( f_0 \subseteq f_1 \) and \( f_1(x(\delta)) = f_0(x(\delta)) = a(\delta) \) for all \( \delta \in S \cap \mu_0 \). For all \( \delta \in S \setminus \delta_\alpha \), the set \( \{ n < \omega \mid \text{supp}(x_{\delta_n,n}) \cap (\text{dom}(f_0) \cup \text{dom}(g_\alpha)) \neq \emptyset \} \) is finite. Thus for all \( \delta \in S \setminus \delta_\alpha \), there is some \( m < \omega \) such that \( f_1(x(\delta)) = h_m(\xi(f(\delta))) = a(\delta) \). Since also \( \{ n < \omega \mid \text{supp}(x_{\delta_n,n}) \cap \text{dom}(f_0) \neq \emptyset \} \) is finite, \( f_1(x(\delta_\alpha)) = g_\alpha(x(\delta_\alpha)) = a(\delta_\alpha) \) holds. So \( f_1 \) uniformizes \( a|\delta_\alpha + 1 \).

Suppose \( a \) is an \( F \)-colouring on \( S \), and \( C = \{ \mu_\alpha \mid \alpha < \omega_1 \} \) is a closed and unbounded subset of \( \omega_1 \) disjoint from \( S \). We define by induction on \( \alpha < \omega_1 \) functions \( f_\alpha : \mu_\alpha \rightarrow F \) such that \( \bigcup_{\alpha < \omega_1} f_\alpha \) is a uniformizing function for \( a \). We may assume \( \mu_0 = 0 \). So let \( f_0 \) be the function with empty domain. Suppose that \( \alpha > 0 \) and, for
all $\gamma < \beta < \alpha$, functions $f_\gamma, f_\beta$, satisfying $f_\gamma \in f_\beta$ and $f_\beta$ uniformizing $a|\mu_\beta + 1$, are defined.

If $\alpha$ is a successor of the form $\beta + 1$, let $f_\alpha : \mu_\alpha \to F$ be some extension of $f_\beta$ which uniformizes $a|\mu_\alpha + 1$. This is possible by \textsuperscript{\textbullet}. If $\alpha$ is a limit ordinal, then $f_\alpha = \bigcup_{\beta < \alpha} f_\beta$ uniformizes $a|\mu_\alpha + 1$ by the induction hypothesis, and since $\mu_\alpha \in C \setminus S$. It follows that $f = \bigcup_{\alpha < \omega_1} f_\alpha$ uniformizes $a$.

\textsuperscript{\textbullet} Suppose $g : \omega_1 \to F$ satisfies $g(x(\delta)) \approx a(\delta)$ for some $\mu < \omega_1$ and for all $\delta \in S \setminus \mu$. By (a) there is $f : \mu \to F$ which uniformizes $a|\mu + 1$. Now, as in the proof of (a), the function $h$ defined for all $\xi < \omega_1$ by

$$h(\xi) = \begin{cases} f(\xi) & \text{if } \xi < \mu = \text{dom}(f); \\ g(\xi) & \text{otherwise} \end{cases}$$

uniformizes $a$.

Remark. It is possible to replace min by max in Definition 2.1(a.ii). It is also possible to replace the filter $D$ in Definition 2.2 by a sequence $\langle D_\delta \mid \delta \in S \rangle$ of filters. Such replacements allow more freedom, but in the proof of Lemma 2.3 one needs to prove by induction the following slightly stronger statement: if $f_0$ and a finite extension of it with domain $\subset \mu_1$ are given, then there is an extension $f_1$ as in Lemma 2.3(a). On the other hand one may like to replace the field by a ring. In this case for Lemma 2.3 to work it is convenient to demand, in addition to Definition 2.1(a), that

the sets $\text{supp}(y_n), n < \omega$, are pairwise disjoint, and for each $n < \omega, y_n$ is such that for every $b$ in the ring $F$ there is a function $f$ with $f(y_n) = b$.

However, in our present work there is no need for these variants.

2.2. Forcing. All forcing arguments are considered to be taking place in the universe $V$ of all sets. Let $\langle P, \leq_P, 1_P \rangle$ be a forcing notion, where $1_P$ is a unique maximal element with respect to the order $\leq_P$. The subscript $P$ from $1_P$ will be omitted everywhere else except in definitions. For all conditions $p$ in $P$, $p \Vdash \phi$ means $p$ forces a sentence $\phi$. If every condition forces $\phi$, we write $\Vdash_P \phi$. The order $\leq_P$ of conditions $p,q \in P$ is interpreted so that $q$ is a stronger condition than $p$ if $q \leq_P p$. Hence for all sentences $\phi$, $p \Vdash \phi$ implies $q \Vdash \phi$, when $q \leq_P p$. The subscript $P$ in the notation $\leq_P$ is not written when $P$ is obvious from the context.

Let $G$ be a $P$-generic set over $V$. When $\sigma$ is a $P$-name, the interpretation of $\sigma$ in the generic extension $V[G]$ is denoted by $\text{int}_G(\sigma)$. For an object $o$ in $V[G]$, a $P$-name for $o$ is written $\dot{o}$, i.e., $\text{int}_G(\dot{o}) = o$. The canonical name for the generic set $G$ itself is $\dot{G}$. If an object $o$ is in $V$, we identify the name $\dot{o}$ with the object $o$ itself instead of using standard names. The only exceptions to these rules are that the standard names for uncountable cardinals and collections $YX$ are written $\omega_1$ and $(\forall X)^V$, respectively, to distinguish them from the cardinals $\aleph_\alpha, \alpha > 0$, and corresponding collections in the generic extension. If $\dot{f}$ is a $P$-name for a function from $X \in V$ into $Y \in V$ and $x \in X$, a condition $p \in P$ decides the value of $f(x)$ when there is $y \in Y$ satisfying $p \Vdash_P \dot{f}(x) = y$.

If $P$ is a forcing notion having $\aleph_2$-c.c., then $P$ preserves all cofinalities $> \aleph_2$, i.e., for all limit ordinals $\theta$, if $\text{cf}(\theta) = \kappa \geq \aleph_2$ in $V$ then $p \Vdash \text{cf}(\theta) = \kappa$. Hence $P$ preserves all cardinals too, i.e., if $\lambda \geq \aleph_2$ is a cardinal in $V$, then $p \Vdash \lambda$ is a cardinal".
Suppose that \( \langle P, \leq_P, 1_P \rangle \) is a forcing notion in \( V \) and \( \tilde{Q}, \tilde{\leq}_Q, \) and \( \tilde{1}_Q \) are \( P \)-names satisfying \( \Vdash_P \) "\( \langle \tilde{Q}, \tilde{\leq}_Q, 1_Q \rangle \) is a forcing notion". The two stage iteration \( \langle P \ast \tilde{Q}, \leq_{P \ast \tilde{Q}}, 1_{P \ast \tilde{Q}} \rangle \) is defined by
\[
P \ast \tilde{Q} = \{ (p, \tilde{q}) \mid p \in P \ \& \ p \Vdash_P \tilde{q} \in \tilde{Q} \},
\]
and for the elements in \( P \ast \tilde{Q} \), \( (p, \tilde{q}) \leq_{P \ast \tilde{Q}} (p', \tilde{q}') \) if both \( p \leq_P p' \) and \( p \Vdash_P (\tilde{q} \leq_{\tilde{Q}} \tilde{q}') \) hold. So \( 1_{P \ast \tilde{Q}} \) is the pair \( (1_P, 1_{\tilde{Q}}) \). We identify elements \( (p, \tilde{q}), (p', \tilde{q}') \in P \ast \tilde{Q} \) if both \( (p, \tilde{q}) \leq_{P \ast \tilde{Q}} (p', \tilde{q}') \) and \( (p', \tilde{q}') \leq_{P \ast \tilde{Q}} (p, \tilde{q}) \) hold. This iteration amounts to the same generic extension as does the composition where one first forces with \( P \) and then with \( \tilde{Q} \).

An iterated forcing of length \( \omega_2 \) with countable support,
\[
(P_{\omega_2}, \leq_{\omega_2}, 1_{P_{\omega_2}}) = \text{CountLim} \langle P_\alpha, \tilde{Q}_\alpha \mid \alpha < \omega_2 \rangle
\]
is inductively defined for all \( \alpha \leq \omega_2 \) as follows.

a) The forcing notion \( \langle P_0, \leq_{P_0}, 1_{P_0} \rangle \) is defined by \( 1_{P_0} = 0 \), \( P_0 = \{ 1_{P_0} \} \), and \( \leq_{P_0} = P_0 \times P_0 \).

b) Suppose, for all \( \beta < \alpha \), that \( \tilde{Q}_\beta, \tilde{\leq}_Q, \tilde{1}_{Q_\beta} \) are given \( P_\beta \)-names and they satisfy \( \Vdash_{P_\beta} "(\tilde{Q}_\beta, \tilde{\leq}_Q, \tilde{1}_{Q_\beta}) \) is a forcing notion".

Moreover, assume that for all \( \beta < \alpha \),
\[
(P_\beta, \leq_{P_\beta}, 1_{P_\beta}) = \text{CountLim} \langle P_\gamma, \tilde{Q}_\gamma \mid \gamma < \beta \rangle
\]
are already defined. It follows from (a) that \( V = V[H] \) for all \( P_0 \)-generic sets \( H \) over \( V \). Hence we assume that \( Q_0, \leq_{Q_0}, 1_{Q_0} \) are standard names and \( \langle Q_0, \leq_{Q_0}, 1_{Q_0} \rangle \) is a forcing notion in \( V \).

The set \( P_\alpha \) is the collection of all functions \( p \) satisfying the following requirements:

i) The domain of \( p \) is \( \alpha \), and for each \( \beta < \alpha \) the value of \( p(\beta) \) is a \( P_\beta \)-name such that \( p(\beta) \Vdash_{P_\beta} \beta \in \tilde{Q}_\beta \).

ii) The set \( \{ \beta < \alpha \mid p(\beta) \Vdash_{P_\beta} \beta \in \tilde{1}_{Q_\beta} \} \) is countable.

c) For all \( \alpha \leq \omega_2 \) and \( p, q \in P_\alpha \), the order of these conditions is \( q \leq_{P_\alpha} p \) if either \( \alpha \) is a limit ordinal, and

\[
\text{for all } \beta < \alpha, \quad q \mid \beta \leq_{P_\beta} p \mid \beta,
\]
or otherwise, \( \alpha \) is a successor ordinal of the form \( \beta + 1 \), and
\[
q \mid \beta \leq_{P_\beta} p \mid \beta,
\]
\[
q \mid \beta \Vdash_{P_\beta} q(\beta) \leq_{Q_\beta} p(\beta).
\]

d) \( 1_{P_\alpha} \) is the function which maps each \( \beta < \alpha \) into \( \tilde{1}_{Q_\beta} \).

Remark. For all \( \alpha \leq \omega_2 \) and \( p \in P_\alpha \), we let \( \text{dom}(p) \) denote the set of ordinals given in (b.ii) above. This set is usually called the support of \( p \). So, one can as well think that the domain of a condition \( p \in P_\alpha \) really is the set \( \text{dom}(p) \). We may write \( f \in P_\alpha, \alpha \leq \omega_2 \), when \( f \) is only a function satisfying \( \text{dom}(f) \in \alpha \) and \( f \cup \{ (\beta, 1_{\tilde{Q}_\beta}) \mid \beta \in \alpha \setminus \text{dom}(f) \} \) is a condition in \( P_\alpha \). We abbreviate \( \Vdash_{P_\alpha} \) by \( \Vdash_{P_\alpha} \) and \( \leq_{P_\alpha} \) by \( \leq_{P_\alpha} \), or even more compactly by \( \leq \) when the subscript is obvious.
For each $\beta < \omega_2$, $P_\beta \ast \tilde{Q}_\beta$ is isomorphic to $P_{\beta+1}$ via the mapping $(p, q) \mapsto p \cap \langle \tilde{q} \rangle$. If $G_\alpha$ is a $P_\alpha$-generic set over $V$, then for each $\beta < \alpha$, $G_\beta$ denotes the $P_\beta$-generic set $\{p|\beta \mid p \in G_\alpha\}$.

**Fact 2.4.** Suppose $\alpha \leq \omega_2$ and $P_\alpha = \text{CountLim} (P_\beta, \tilde{Q}_\beta \mid \beta < \alpha)$.

a) If $P_\beta$ has $\aleph_2$-c.c. for all $\beta < \alpha$, then $P_\alpha$ has $\aleph_2$-c.c.

b) If $\alpha = \omega_2$, $P_\omega$ has $\aleph_2$-c.c., $X$ is a set in $V$, and $\tilde{Y}$ is a $P_{\omega_2}$-name satisfying $\Vdash_{\omega_2} (\tilde{Y} \in X \& \text{card} (\tilde{Y}) < \omega_2)$, then for all $P_{\omega_2}$-generic sets $G$ over $V$, there is $\alpha < \omega_2$ such that the subset $Y = \text{int}_G (\tilde{Y})$ is already in $V[G_\alpha]$.

c) Let $S$ be a set of limit ordinals $< \omega_1$ and $F$ a field of cardinality $\leq \aleph_1$. If $2^{\aleph_1} = \aleph_2$ and $\Vdash_\beta (\text{card} (Q_\beta) = \text{card} (\omega_1))$ for all $\beta < \alpha$, then there is a collection $\{\tilde{e}^{\alpha, \gamma} \mid \gamma < \omega_2\}$ of $P_\alpha$-names satisfying $\Vdash_\alpha \{\tilde{e}^{\alpha, \gamma} \mid \gamma < \omega_2\} = \text{Col}_{S,F}$. Such a collection is called a $(P_\alpha, \omega_2)$-enumeration for $\text{Col}_{S,F}$.

For $\alpha < \beta \leq \omega_2$, $p \in P_\alpha$ and $q \in P_\beta$ such that $p \leq_\alpha q(\alpha)$, the “composition” of these conditions, in symbols $p \perp_\alpha q$, is the function having domain $\alpha$ and defined for all $\gamma < \alpha$ by

$$(p \perp_\alpha q)(\gamma) = \begin{cases} p(\gamma) & \text{if } \gamma < \beta; \\ q(\gamma) & \text{if } \beta \leq \gamma < \alpha. \end{cases}$$

Then, as in [She77] Definition 1.1 and Fact 1.3] or [Go93] Definition 1.12 and Fact 1.13, $p \perp_\alpha q$ is a condition in $P_\beta$ and $(p \perp_\alpha q) \leq_\beta q$.

We shall also need the “quotient” forcing notion $\langle \tilde{P}_{\alpha, \beta}, \leq_{\alpha, \beta}, \tilde{1}_{\alpha, \beta} \rangle$ of an iterated forcing $P_\beta = \text{CountLim} (P_\gamma, \tilde{Q}_\gamma \mid \gamma < \beta)$, where $\alpha < \beta \leq \omega_2$. The following definition is from [Go93]. The $P_\alpha$-name $\tilde{P}_{\alpha, \beta}$ is such that

$$\Vdash_\alpha \tilde{P}_{\alpha, \beta} = \{ p \in P_\beta \mid p|\alpha \in \tilde{G}_\alpha \},$$

where $\leq_{\alpha, \beta}$ is a $P_\alpha$-name for which

$$\Vdash_\alpha (\leq_{\alpha, \beta} = \leq_\beta |\tilde{P}_{\alpha, \beta}),$$

and $\tilde{1}_{\alpha, \beta}$ is the standard name for $\tilde{1}_{P_\beta}$. So, for all $P_\alpha$ generic sets $H$ over $V$ and $p, q \in \tilde{P}_{\alpha, \beta} = \text{int}_H (\tilde{P}_{\alpha, \beta})$, we have $p \leq_{\alpha, \beta} q$ in $V[H]$ iff $p \leq_\alpha q$ in $V$, where $\leq_{\alpha, \beta} = \text{int}_H (\leq_{\alpha, \beta})$. We abbreviate $\Vdash_{P_\alpha, \beta}$ by $\Vdash_{\alpha, \beta}.$

**Fact 2.5.** Suppose $\alpha < \beta \leq \omega_2$, $H$ is a $P_\alpha$-generic set over $V$, $\tilde{o}$ is a $P_\beta$-name, and $\phi$ is a formula. Then there is a $P_{\alpha, \beta}$-name $\tilde{o}$ in $V[H]$ such that the following hold.

a) If $p \in P_\beta$, $p|\alpha \in H$, and $p \Vdash_\beta \phi (\tilde{o})$, then in $V[H]$ there is $q \in P_{\alpha, \beta}$ such that $q \leq_{\alpha, \beta} p$ and $q \Vdash_{\alpha, \beta} \phi (\tilde{o})$.

b) If $p \in V[H]$, $r \in P_{\alpha, \beta}$, and $r \Vdash_{\alpha, \beta} \phi (\tilde{o})$, then in $V$ there is $s \in P_\beta$ satisfying $s \leq_\beta r$, $s|\alpha \in H$, and $s \Vdash_\beta \phi (\tilde{o})$.

**Fact 2.6.** Suppose $\alpha \leq \beta \leq \omega_2$, $p, q \in P_\beta$, and $H$ is a $P_\beta$-generic set over $V$. If both $p|\alpha \in H$ and $q|\alpha \in H$ hold, then there are $p', q' \in P_\beta$ such that $p' \leq_\beta p$, $q' \leq_\beta q$, and $p'|\alpha = q'|\alpha \in H$. 
3. The Combinatorial Problem

This section is devoted to the proof of the following theorem, which is a precise form of the theorem described in the introduction.

**Theorem 2.** Assume the following properties hold in $V$:

- the generalized continuum hypothesis, GCH;
- $S$ is a set of limit ordinals below $\omega_1$ and bistationary in $\omega_1$;
- $F$ is a finite field;
- Vec is the vector space over $F$ freely generated by $(x_\xi \mid \xi < \omega_1)$;
- $D$ is a filter over $\omega_1$ including all cofinite sets of $\omega$.

Then there is a forcing notion $(P, \leq, 1)$ of cardinality $\aleph_2$ such that $P$ satisfies $\aleph_2$-cc, $P$ does not add new countable sequences, and for every $P$-generic set $G$ over $V$, there is in $V[G]$ a Vec-ladder system $x$ on $S$ such that $\text{card}(\text{Col}_{S,F}/\text{Unif}_{x,D}) = \text{card}(F)$.

Recall that the conclusion of the theorem is equivalent to the number of pairwise nonequivalent $F$-colourings on $S$ w.r.t. $x$ and $D$ being $\text{card}(F)$. The idea of the proof will be similar to the proof of [She81a, Theorem 1].

From now on, all Vec-ladders on $\delta$ and Vec-ladder systems on $S$ are called simply ladders on $\delta$ and ladder systems, all $F$-colourings on $S$ are called colourings for short, and $\text{Col}$ denotes the set of all $F$-colourings on $S$. The subspace of $\text{Col}$ generated by a colouring $b$ is denoted for short by $(b)$.

### 3.1. Definition of the Forcing

To define an iterated forcing

$$P = \text{CountLim} \langle P_\alpha, \bar{Q}_\alpha \mid \alpha < \omega_2 \rangle$$

it suffices to define names for forcing notions $(\bar{Q}_\alpha, \leq_{\bar{Q}_\alpha}, \bar{1}_{\bar{Q}_\alpha})$ by induction on $\alpha < \omega_2$.

The forcing notion $(Q_0, \leq_{Q_0}, 1_{Q_0})$ is defined as follows. The set $Q_0$ is $\text{ILad} \times \text{ICol}$, where

$$\text{ILad} = \{ z \theta \mid z \text{ is a ladder system } \& \, \theta < \omega_1 \},$$

$$\text{ICol} = \{ c \mu \mid c \in \text{Col } \& \, \mu < \omega_1 \}.$$  

We shorten our notation for $p = (z \theta, c \mu) \in Q_0$ by writing

$$p[1] \text{ for } z \theta \text{ and } p[2] \text{ for } c \mu,$$

$$\varepsilon \leq \text{dom}(p) \text{ if } \varepsilon \leq \min \{ \theta, \mu \}, \text{ and}$$

$$\text{dom}(p) \leq \varepsilon \text{ if } \max \{ \theta, \mu \} \leq \varepsilon.$$  

For all $p_0, p_1 \in Q_0$, we define $p_1 \leq_{Q_0} p_0$ iff $p_1$ coordinatewise extends $p_0$, i.e., $p_1[1] \supseteq p_0[1]$ and $p_1[2] \supseteq p_0[2]$. The pair of functions with empty domain is the maximal element $1_{Q_0}$ of $Q_0$. If $X \subseteq Q_0$ is a set of pairwise compatible conditions, then we define

$$\bigcup \{ p \mid p \in X \} = \bigcup \{ p[1] \mid p \in X \}, \bigcup \{ p[2] \mid p \in \{ X \} \}.$$  

Note that $Q_0$ is $\aleph_1$-closed (which means every descending $\omega$-chain of conditions has a lower bound). Hence $Q_0$ does not add new countable sequences and $\aleph_1$ is not collapsed.
For every $P_1$-generic set $G_1$ there are $P_\alpha$-names $\vec{x}$ and $\vec{b}$, for $\alpha = 1$ (later on $\alpha$ might be any index in $\omega_2 \setminus \{0\}$), such that
\[
\models_\alpha \vec{x} = \bigcup \{p(0)[1] \mid p \in G_\alpha\},
\]
\[
\models_\alpha \vec{b} = \bigcup \{p(0)[2] \mid p \in G_\alpha\}.
\]
So, these names together with a generic set determine a ladder system and a colouring. Hereafter uniform and equivalent mean uniform and equivalent w.r.t. the generic ladder system $\vec{x}$ and the filter $D$. Hence Unif denotes the set of all uniform colourings w.r.t. $\vec{x}$ and $D$. Observe that the generic colouring $\vec{b}$ satisfies $\models_1 (\vec{b} \notin \text{Unif})$, as we shall prove in Lemma 3.6.

Forcing notions $(\vec{Q}_\alpha, \preceq_{\vec{Q}_\alpha}, \text{U}_q)$, for $1 \leq \alpha < \omega_2$, are defined in such a way that each $\vec{Q}_\alpha$ “kills” an undesirable colouring. In order to ensure that all undesirable colourings will be killed, a bookkeeping function will be needed. Fix a function $\pi$ from $\omega_2$ onto $\omega_2 \times \omega_2$ such that whenever $\pi(\alpha) = (\beta, \gamma)$, then $\beta \leq \alpha$.

The bookkeeping function is useful only if we can ensure that the colourings can be enumerated by $\omega_2$. Since we assume GCH, the cardinality of Col is $\text{card}(\beta(\omega_2)) = (2^\aleph_0)^{\aleph_1} = \aleph_1^{\aleph_0} = \aleph_2$. Hence there is an enumeration $\{\vec{e}^{\beta,\gamma} \mid \gamma < \omega_2\}$ for Col in $V$. By Fact 2.4(c) the existence of a $(P_\alpha, \omega_2)$-enumeration for Col follows for $1 \leq \alpha < \omega_2$, if we show that for each $\beta < \alpha$,

\[
(1) \quad \models_\beta \text{card}(\vec{Q}_\beta) \leq \text{card}(\vec{\omega}_1).
\]

Since $P_0$ is the trivial forcing $\{1\}$, $2^{\aleph_0} = \aleph_1$, and $\text{card}(\text{Col}) = \text{card}(\text{ILad}) = (2^{\aleph_0})^{\aleph_0} = \aleph_1^{\aleph_0} = \aleph_2$, we have that $\text{card}(Q_0) = \aleph_1$, and so (1) holds trivially when $\beta = 0$.

Suppose $1 \leq \alpha < \omega_2$. Our induction hypothesis is that for each $\beta < \alpha$, there is a $(P_\beta, \omega_2)$-enumeration $\{\vec{e}^{\beta,\gamma} \mid \gamma < \omega_2\}$ for Col, and that $\models_\beta (\text{card}(\vec{Q}_\beta) = \text{card}(\vec{\omega}_1))$ holds. It follows from Fact 2.4(c) that there also exists a $(P_\alpha, \omega_2)$-enumeration $\{\vec{e}^{\alpha,\gamma} \mid \gamma < \omega_2\}$ for Col.

**Definition 3.1.** Suppose $\pi(\alpha) = (\beta, \gamma)$. Then $\beta \leq \alpha$ and $\vec{e}^{\beta,\gamma}$ has been defined. We define $\vec{a}^\alpha$ to be a $P_\alpha$-name which refers to the same colouring as the $P_\beta$-name $\vec{e}^{\beta,\gamma}$, i.e., for every $P_\alpha$-generic set $\mathcal{H}$ over $V$, $\text{int}_H(\vec{a}^\alpha) = \text{int}_H(\vec{e}^{\beta,\gamma})$. A $P_\alpha$-name $\vec{Q}_\alpha$ is defined by
\[
\models_\alpha \vec{Q}_\alpha = \begin{cases} 
\{\vec{1}_{\vec{Q}_\alpha}\} & \text{if } \vec{a}^\alpha \in \langle \vec{b} \rangle + \text{Unif}; \\
\text{Uf}(\vec{a}^\alpha) & \text{otherwise};
\end{cases}
\]
where $\vec{1}_{\vec{Q}_\alpha}$ is the standard name for the function having empty domain, and $\text{Uf}(\vec{a}^\alpha)$ is a $P_\alpha$-name satisfying
\[
\models_\alpha \text{Uf}(\vec{a}^\alpha) = \{f \mid \mu < \vec{\omega}_1 \land f : \mu \to F \text{ uniformizes } \vec{a}^\alpha|\mu + 1\}.
\]

A $P_\alpha$-name $\vec{Q}_\alpha$ is defined by $\models_\alpha$ (for all $p, q \in \vec{Q}_\alpha$, $p \preceq_{\vec{Q}_\alpha} q$ iff $p \preceq q$).

For every $p \in P_\alpha$, an index $\beta \leq \alpha$ is called $p$-trivial if $\beta > 0$ and $p|\beta \models \vec{Q}_\beta = \{1\}$. Observe that if $\beta \in \text{dom}(p)$ then $p|\beta \not\models (p(\beta) = 1)$, and $\beta$ is not $p$-trivial. Note also that $\models_\alpha (\text{Uf}(\vec{a}^\alpha) \neq \{1\})$ by Lemma 2.3(a). In fact, if $p \in P_\alpha$ and $p$ forces $(\vec{a}^\alpha \notin \langle \vec{b} \rangle + \text{Unif})$, then $p$ forces $\vec{Q}_\alpha$ to be a nontrivial forcing notion (see Lemma 3.4(d) below).
We have to check that property (1) holds for $\beta = \alpha$. We shall prove that $P_\alpha$ does not add new countable sequences. Hence $\Vdash_{\alpha} (\langle \omega_1^F \rangle^\gamma = \omega_1^F$. This implies that
\[ \Vdash_{\alpha} \text{card}(\tilde{Q}_\alpha) \leq \text{card}(\langle \omega_1^F \rangle^\alpha) = \text{card}(\omega_1), \]

since $\text{card}(\omega_1^F) = 2^{|\alpha|} = \aleph_1$.

Before proving that $P_\alpha$ does not add new countable sequences, we introduce useful notations and lemmas. Let $H_\beta$, for $\beta \leq \alpha$, denote the model
\[ \langle H(\lambda), \in, \beta, S, F, D, \langle (P_\gamma \leq, 1) \mid \gamma \leq \beta \rangle \rangle, \]

where $\lambda$ is “some large enough” cardinal, for example $(\beth_2)^+$, and $H(\lambda)$ is the set of all sets hereditary of cardinality $< \lambda$. The expansion of the model $H_\beta$ with new constant symbols “$X_1, X_2, \ldots$” is denoted by $H_\beta(X_1, X_2, \ldots)$.

A condition $p$ in $P_\alpha$ has height $\epsilon$, where $\beta \leq \alpha$ and $\epsilon < \omega_1$, if for every $\gamma \in \text{dom}(p)$, $p|\gamma \Vdash_{\gamma} \text{dom}(p(\gamma)) = \epsilon$. We say that $p$ is of height $< \epsilon$ when $p|\gamma \Vdash_{\gamma} \text{dom}(p(\gamma)) < \epsilon$. The notion $p$ is of height $\geq \epsilon$ is defined analogously. These notions are from [She81a].

If $X$ is a set of pairwise compatible conditions in $P_\alpha$, the “composition” of these conditions, in symbols $\bigcup_{p \in X} p$, is the function $f$ with $\text{dom}(f) = \bigcup_{p \in X} \text{dom}(p)$ and for each $\beta \in \text{dom}(f)$, $f(\beta)$ is a $P_\beta$-name such that
\[ \Vdash_{\beta} f(\beta) = \begin{cases} \bigcup \{ p(0) \mid p \in X \} & \text{if } \beta = 0; \\ \bigcup \{ p(\beta) \mid p \in X \} & \text{otherwise.} \end{cases} \]

Observe that $f$ is not necessarily a condition in $P_\alpha$ (as we pointed out earlier, by this we mean that not even the extended function $f \cup \{(\beta, 1) \mid \beta \in \alpha \setminus \text{dom}(f)\}$ is a condition in $P_\alpha$).

**Lemma 3.2.**

a) Suppose $\beta \leq \alpha$, $\langle p_n \mid n < \omega \rangle$ is a descending chain of conditions in $P_\beta$, $\theta < \omega_1$ is a limit ordinal not in $S$, and $\langle \theta_n \mid n < \omega \rangle$ is an increasing sequence of ordinals with limit $\theta$. Suppose also that, for all $\gamma < \beta$,
  i) there are infinitely many $m < \omega$ for which $p_m|\gamma \Vdash_{\gamma} \text{dom}(p_m(\gamma)) \geq \theta_m$, and
  ii) there are infinitely many $n < \omega$ such that $p_n|\gamma \Vdash_{\gamma} \text{dom}(p_n(\gamma)) < \theta$.

Then $q = \bigcup_{n < \omega} p_n$ is a condition in $P_\beta$, $q \leq p_n$ for every $n < \omega$, and $q$ has height $\theta$.

b) For all $\beta \leq \alpha$, $p \in P_\beta$, and $\epsilon < \omega_1$ there are $q \leq p$ in $P_\beta$ and $\theta < \omega_1$ such that $\epsilon \leq \theta$ and $q$ has height $\theta$.

**Proof.** The idea of the proof is similar to [She77 Lemma 1.5].

a) We prove the claim by induction on $\beta \leq \alpha$. If $\beta = 1$ then $q \in P_1 \subseteq V$, and clearly the other properties hold too. Suppose $\beta > 1$ and for every $\gamma < \beta$ we have $q|\gamma \in P_\gamma$, $q|\gamma \leq p_n|\gamma$ for all $n < \omega$, and $q|\gamma$ has height $\theta$. If $\beta$ is a limit ordinal then the claim holds directly by the definition of $P_\beta$ and height. Note that $\text{dom}(q)$ is countable even if $\beta$ has cofinality $> \omega$, since $\text{dom}(q)$ is a countable union of countable sets.

Suppose $\beta = \gamma + 1$ and $\gamma \in \text{dom}(q)$ (if $\gamma \notin \text{dom}(q)$ then the claim follows from the induction hypothesis). By the definition of $q$, $q|\gamma \Vdash \bigcup_{n < \omega} p_n(\gamma) = q(\gamma)$. By (a.ii) and (a.i), $q|\gamma$ forces that $\text{dom}(q(\gamma)) = \bigcup_{m < \omega} \theta_m = \theta$. Since $\theta \notin S$ and
such that

\[ q \gamma \vdash \gamma n_\gamma p_n(\gamma) \in \tilde{Q}_\gamma, \]

\[ q \gamma \vdash \gamma \bigcup_{n<\omega} p_n(\gamma) = q(\gamma) \text{ uniformizes } \tilde{a}^\gamma | \theta + 1. \]

Consequently, \( q \in P_\beta, q \leq p_n \) for all \( n < \omega \), and \( q \) has height \( \theta \).

b) Again we work by induction on \( \beta \leq \alpha \). If \( p \in P_1 \) and \( 0 \in \text{dom}(p) \), then any extension \( q \in P_1 \) of \( p \) for which \( \text{dom}(q(0)) \geq \epsilon \) suffices to prove the claim. Suppose \( \beta = \gamma + 1, \gamma \in \text{dom}(p) \), and, as the induction hypothesis, \( r \leq_\gamma p | \gamma \) is a condition in \( P_\gamma \) having height \( \theta \geq \epsilon \). Since \( p | \gamma \geq_\gamma r \vdash_\gamma (p(\gamma) \in \tilde{Q}_\gamma) \) we get by Lemma 2.3(a) that \( r \) forces

there is \( x \in \tilde{Q}_\gamma \) for which \( x \leq_\theta p(\gamma) \) & dom(\( x \)) \geq \theta.

By the Maximal Principle there is a \( P_\gamma \)-name \( \tilde{f} \) satisfying the above formula, and, moreover, we may assume \( r \vdash_\gamma \text{dom}(\tilde{f}) = \theta \). Define a condition \( q \in P_\beta \) by \( q | \gamma = r \) and \( q(\gamma) = \tilde{f} \). Then \( q \) has height \( \theta \).

Suppose that \( \beta \) is a limit ordinal, and for all \( p' \in P_\beta, \gamma < \beta \), and \( \epsilon' < \omega_1 \) there is a condition \( r \) in \( P_\gamma \) satisfying \( r \leq p' | \gamma \) and \( r \) has height \( \theta' \geq \epsilon' \). We assume that the supremum of \( \text{dom}(p) \) is \( \beta \) (otherwise the claim follows by the induction hypothesis). We define by induction on \( n < \omega \) a descending chain \( \langle q_n | n < \omega \rangle \) of conditions in \( P_\beta \) such that \( q = \bigcup_{n<\omega} q_n \) will be a condition in \( P_\beta \) and \( q \) has height \( \theta \geq \epsilon \).

Let \( \langle \gamma_n | n < \omega \rangle \) be an increasing sequence of ordinals with limit \( \beta \) (\( \beta = \sup(\text{dom}(p)) \) must be of cofinality \( \omega \)). Note that the set of all \( \theta < \omega_1 \), for which

there is a countable elementary submodel \( \mathcal{M} \)

of \( H_\beta(p, \gamma_n)_{n<\omega} \) such that \( \mathcal{M} \cap \omega_1 = \theta \),

is closed and unbounded in \( \omega_1 \). Because \( S \) is bistationary in \( \omega_1 \), we can choose a countable elementary submodel \( \mathcal{M} \) of the model \( H_\beta(p, \gamma_n)_{n<\omega} \) for which \( \mathcal{M} \cap \omega_1 = \theta \geq \epsilon \) and \( \theta \not\in S \). Let \( \langle \epsilon_n | n < \omega \rangle \) be an increasing sequence of ordinals with limit \( \theta \) (\( \epsilon_n \in \mathcal{M} \) for every \( n < \omega \)). The model \( \mathcal{M} \) satisfies our induction hypothesis and \( p, \gamma_0 \in \mathcal{M} \); thus there is a condition \( r_0 \leq p | \gamma_0 \) in \( P_\gamma \cap \mathcal{M} \) having height greater than \( \epsilon_0 \). We define \( q_0 \) to be \( r_0 \uplus p \) (which really is a condition in \( P_\beta \cap \mathcal{M} \)). Similarly, when the condition \( q_n \in P_\beta \cap \mathcal{M} \) is defined we can find a condition \( q_{n+1} \in P_\beta \cap \mathcal{M} \) such that \( q_{n+1} \leq \beta q_n \) and the initial segment \( q_{n+1} | \gamma_{n+1} \) has height greater than \( \epsilon_{n+1} \). So (a.ii) holds for \( \langle q_n | n < \omega \rangle \) and \( \langle \epsilon_n | n < \omega \rangle \). Since the conditions \( q_n, n < \omega \), are in \( \mathcal{M} \) and \( \mathcal{M} \cap \omega_1 = \theta \), also (a.ii) is satisfied. It follows from (a) that \( q = \bigcup_{n<\omega} q_n \) is a condition in \( P_\beta \) having height \( \theta \geq \epsilon \).

Now we are ready to show that \( P_\alpha \) is \( \delta_1 \)-distributive (see the next lemma). Hence it will follow that \( \delta_1 \) is not collapsed and, for every \( P_\alpha \)-generic set \( G_\alpha \) over \( V \), if \( X \in V \) and \( V[G_\alpha] \models (f : \mu \to X \text{ and } \mu < \omega_1) \), then \( f \) is already in \( V \).

Lemma 3.3. If \( E_n, n < \omega \), are dense and open subsets of \( P_\alpha \), then \( \bigcap_{n<\omega} E_n \) is dense.

Proof. Let \( \mathcal{M} \) be a countable elementary submodel of \( H_\alpha(p, E_n)_{n<\omega} \) for which \( \mathcal{M} \cap \omega_1 = \epsilon \in \omega_1 \) and \( \epsilon \not\in S \) (for the existence of such a model, see the proof of Lemma 3.2(b)). Fix an increasing sequence \( \langle \epsilon_n | n < \omega \rangle \) of ordinals with limit \( \epsilon \).
We define by induction on \( n < \omega \) conditions \( q_n \in P_\alpha \) such that, for each \( n < \omega \),
\[
q_n \in E_n, \\
q_n \text{ is of height } \geq \epsilon_n, \\
q_n \geq q_{n+1}.
\]

Since \( \mathcal{M} \) is an elementary submodel, \( E_0 \cap \mathcal{M} \) is a dense subset of \( P_\alpha \cap \mathcal{M} \). So there is a condition \( r \in E_0 \cap \mathcal{M} \) stronger than \( p \). We let \( q_0 \) be some extension of \( r \) having a height greater than \( \epsilon_0 \). This is possible since \( \epsilon_0 \) is in \( \mathcal{M} \), and \( \mathcal{M} \) is an elementary submodel of \( \mathcal{H}_\alpha(p, E_n)_{n<\omega} \) which satisfies Lemma 3.2(b). Moreover, \( q_0 \) is in \( E_0 \) since \( E_0 \cap \mathcal{M} \) is an open subset of \( P_\alpha \cap \mathcal{M} \). Similarly, if \( q_n \in P_\alpha \cap \mathcal{M} \) is already defined, we can find \( q_{n+1} \in P_\alpha \cap \mathcal{M} \) satisfying the properties given above.

As in the proof of Lemma 3.2(b), \( q = \bigcup_{n<\omega} q_n \) really is a condition in \( P_\alpha \). Now \( q \leq q_n \) for each \( n < \omega \), and since \( E_n \), \( n < \omega \), are open sets, it follows that \( q \in \bigcap_{n<\omega} E_n \). \( \square \)

From the preceding lemma it follows that for all \( \alpha \leq \omega_2 \) and \( p \in P_\alpha \) there is \( q \leq p \) in \( P_\alpha \) satisfying the following property: for every \( \beta < \alpha \), \( q|\beta \) decides the value of \( q(\beta) \) (this fact can be proved using the same kind of induction as the proof of Lemma 3.2(b)). Hence, from now on, the reader can think, if he or she wants, that all conditions in \( P_\alpha \) are “real” functions from \( \alpha \) into \( <\omega \Gamma \), not just “normal” conditions with names for sequences. In particular, this thought might be helpful during the first reading of Lemma 3.8 below. But we shall use the following conventions. We write \( \text{dom}(p(\beta)) = \epsilon \), where \( p \in P_\alpha \), \( \alpha \leq \omega_2 \), \( \beta \in \text{dom}(p) \setminus \{0\} \), and \( \epsilon \in \omega_1 \), when \( p \) is a condition which satisfies \( p|\beta \upharpoonright p \cdot \text{dom}(p)(\beta) = \epsilon \). Similarly, we write \( \xi \in \text{dom}(p(\beta)) \) if \( p|\beta \upharpoonright p \cdot \text{dom}(p(\beta)) \), and for \( c \in F \) we write \( p(\beta)(\xi) = c \) if \( \xi \in \text{dom}(p(\beta)) \) and \( p|\beta \upharpoonright p(\beta) \cdot \xi = c \).

We define \( g_\alpha \), for nonzero \( \alpha < \omega_2 \), to be the generic function determined by \( \tilde{Q}_\alpha \), i.e., \( \tilde{g}_\alpha \) is a \( P_\alpha \)-name satisfying
\[
\Vdash_{\alpha+1} \tilde{g}_\alpha = \bigcup \{ p(\alpha) \mid p \in \tilde{G} \}.
\]
Then \( g_\alpha \) is a function in \( V[H] \) for any \( P_{\alpha+1} \)-generic set \( H \), since \( H \) contains only compatible conditions. Note that in \( V[H] \), \( g_\alpha \) is the function with empty domain iff \( Q_\alpha \neq \text{Unif}(a^\alpha) \).

**Lemma 3.4.**

a) The forcing notion \( P \) is of cardinality \( \aleph_2 \), and it satisfies \( \aleph_2 \)-c.c.

b) \( P \) does not add new countable sequences.

c) For every \( P \)-generic set \( G \) over \( V \), \( V[G] \) satisfies GCH and \( (\langle \mathcal{N}_\alpha \rangle)V = \mathcal{N}_\alpha \) for all ordinals \( \alpha \).

d) For all nonzero \( \alpha < \omega_2 \) and \( P_{\alpha+1} \)-generic sets \( G_{\alpha+1} \) over \( V \), \( V[G_{\alpha+1}] \models a^\alpha \in \langle b \rangle + \text{Unif} \).

e) For every \( P \)-generic set \( G \) over \( V \), \( V[G] \models \text{card}(\text{Col}/\text{Unif}) \leq \text{card}(F) \).

**Proof.** Even though all the properties are standard, we sketch proofs for them.

a) The claim follows directly by the property (I) and Fact 2.4(a).

b) If we assume that there is a new subset of \( \omega \) in \( V[G] \), where \( G \) is a \( P \)-generic set over \( V \), then by the \( \aleph_2 \)-c.c. property of \( P \) and Fact 2.4(b) we can choose \( \alpha < \omega_2 \) such that the new subset is already in \( V[G_\alpha] \). This contradicts Lemma 3.3.
c) The generalized continuum hypothesis is preserved by (a), (b), and by the following well-known fact:

if \( \text{card}(P) \leq \aleph_2 \), \( P \) has \( \aleph_2 \)-c.c., \( 2^{\aleph_1} = \aleph_2 \), \( \lambda \) is an uncountable cardinal, and \( \theta = (\aleph_2^\lambda)^V \), then \( \models \text{p}2^\lambda \leq \theta \).

By (a) the ordinals \( \aleph_\alpha^V, \alpha \geq 2 \), are cardinals in the generic extension. Since by (b) \( \aleph_1^V \) is not collapsed, the claim follows.

d) Let \( G_{\alpha+1} \) be a \( P_{\alpha+1} \)-generic set over \( V \). If \( (Q_\alpha = \{1\}) \) holds in \( V[G_\alpha] \), then by Definition 3.1 \( V[G_\alpha] \models \text{Unif} \in \langle b \rangle + \text{Unif} \). Since \( V[G_{\alpha+1}] \supseteq V[G_\alpha] \), the latter formula is also satisfied in \( V[G_{\alpha+1}] \).

Suppose \( (Q_\alpha = \text{Unif}(\text{a}^\alpha)) \) holds in \( V[G_\alpha] \). By Lemma 2.3(a), for each \( \xi < \omega_1 \) the generic set \( G_{\alpha+1} \) contains a condition \( p \) for which \( p[\alpha] \models \xi \in \text{dom}(p(\alpha)) \). Thus \( \text{dom}(g_{\alpha}) = \omega_1 \) in \( V[G_{\alpha+1}] \). Let \( f_p \) be a shorthand for int\( g_{\alpha+1}(p(\alpha)) \). Then \( f_p \) uniformizes \( \text{a}^\alpha \) \( (\text{dom}(f_p) + 1) \) in \( V[G_{\alpha+1}] \). Consequently, \( g_{\alpha} = \bigcup \{f_p \mid p \in G_\alpha \} \) uniformizes \( \text{a}^\alpha \) in \( V[G_{\alpha+1}] \). So \( V[G_{\alpha+1}] \models \text{a}^\alpha \in \langle b \rangle + \text{Unif} \).

e) Assume the claim fails. Since \( \text{card}(\langle b \rangle_{p}) \leq \text{card}(F) \), let \( G \) be a \( P \)-generic set over \( V \) and \( \text{d} \) a colouring in \( V[G] \) for which \( \text{d} \notin \langle b \rangle + \text{Unif} \). Since \( P \) has \( \aleph_2 \)-c.c. and \( \models P (\text{card}(\text{d}) < \omega_2) \), there must be, by Fact 2.4(b), \( \beta < \omega_2 \) such that \( \text{d} \in V[G_\beta] \).

By the definition of the forcing \( P \) and Fact 2.4(c), \( \{c^{\beta, \gamma} \mid \gamma < \omega_2 \} = \text{Col} \) holds in \( V[G_\beta] \). So there is \( \gamma < \omega_2 \) with \( V[G_\beta] \models \text{d} = c^{\beta, \gamma} \). By Definition 3.1 and since the bookkeeping function \( \pi \) is surjective, there is \( \alpha < \omega_2 \) such that \( (\text{a}^\alpha = c^{\beta, \gamma}) \) holds in \( V[G_\alpha] \). Then, by (d), \( V[G_{\alpha+1}] \) satisfies \( \text{a}^\alpha \in \langle b \rangle + \text{Unif} \). Since \( V[G_{\alpha+1}] \subseteq V[G] \), we see that \( (c^{\beta, \gamma} = \text{a}^\alpha = \text{d} \in \langle b \rangle + \text{Unif}) \) holds in \( V[G] \), contrary to our initial assumption.

\( \square \)

Remark. It can be seen from the constructions in Subsection 3.2 below that \( P \) is a proper forcing notion [Shes82b, Theorem 2.8(1) on page 86]. But this fact does not, however, help with the main problem of Subsection 3.2.

3.2. The Generic Colouring is Nonuniform. The main problem left after Lemma 3.4 is that maybe the size of \( \text{Col}/\text{Unif} \) is smaller than the size of \( \text{F} \) in the generic extension. Since \( \text{card}(\text{Col}/\text{Unif}) < \text{card}(\text{F}) \) implies \( \text{Col} = \text{Unif} \), we may, equivalently, suspect that the generic colouring \( \text{b} \) is uniform in the generic extension. As a preliminary lemma we want to show that the generic colouring \( \text{b} \) is initially nonuniform, but first we have to prove the following auxiliary lemma.

**Lemma 3.5.**

a) Suppose \( p \in P_\alpha, \alpha \leq \omega_2, \delta \in S, \) and \( \text{dom}(p(0)) \leq \delta \). If \( \bar{\gamma} \) is a ladder on \( \delta \), and \( \bar{c} \) is an \( \omega \)-sequence of elements in \( F \), then there is \( q \leq p \) satisfying

\[
\text{dom}(q) = \text{dom}(p) \cup \{0\}, \\
p(\alpha \setminus \{0\}) = q(\alpha \setminus \{0\}), \\
q \models \text{Unif}(\delta) = \bar{\gamma} \ & \text{and} \ & \text{b}(\delta) = \bar{c}.
\]

b) Suppose \( p \in P_\alpha, \alpha \leq \omega_2, A \) is a finite subset of \( \alpha \setminus \{0\}, \langle c_\beta \mid \beta \in A \rangle \) is a sequence of elements in \( F \), and \( \langle y_\beta \mid \beta \in A \rangle \) is a sequence of elements in \( \text{Vec} \) such that \( \text{supp}(y_\beta) \notin \text{dom}(p(\beta)) \). Then there is a condition \( s \leq p \) in \( P_\alpha \) satisfying for all \( \beta \in A \) that

either \( \beta \) is \( s \)-trivial or \( s(\beta)(y_\beta) = c_\beta \).
Furthermore, if for each $\beta \in A$,

$$p|\beta \parallel \beta Q_\beta = \text{Unif}(\bar{a}^\beta),$$

then we can also ensure that

$$\text{dom}(s) = \text{dom}(p) \cup A,$$
$$p|((\alpha \setminus A) = s|((\alpha \setminus A),$$
$$\text{dom}(s(\beta)) = \max(\text{supp}(y_\beta)) + 1.$$

Proof. This proof is essentially the same as the proof of $[\text{She}]$ Lemma 1.5.

a) Define $r \in Q_0$ to be any extension of $p(0)$ which satisfies $r[1]|(\delta) = \bar{y}$ and $r[2](\delta) = \bar{c}$. Then $q$ defined by $\text{dom}(q) = \{0\}$ and $q(0) = r$ is a condition in $P_1$. Moreover, $q \leq p1$, and thus the condition $q \cup p$ is as required in the lemma.

b) It suffices to prove the lemma when $A$ is a singleton $\{\beta\}$, since the result for larger sets follows by induction (of course, a different induction depending on $[A]$).

If $[A]$ holds, then define $q = p$; otherwise let $q \leq p$ in $P_\alpha$ be such that either $\beta$ is $q$-trivial or $q|\beta$ forces $Q_\beta$ to be nontrivial. If $\beta$ is $q$-trivial then $s = q$ is as wanted. Otherwise, assume $q|\beta$ forces $Q_\beta$ to be nontrivial. Let $\theta$ be $\max(\text{supp}(y_\beta))$. By Lemma 2.3(a) (as in the proof of Lemma 3.2(b)) there is a $P_\beta$-name $\bar{f}$ for which

$$q|\beta \parallel \beta \bar{f} \in Q_\beta \& q(\beta) \hspace{0.5em} \bar{f} \& \theta \in \text{dom}(\bar{f}).$$

Define $\bar{g}$ to be a $P_\beta$-name for a function such that

$$q|\beta \parallel \beta (\text{dom}(\bar{g}) = \theta + 1 \& \bar{f}|\theta = \bar{g}|\theta \& \bar{g}(y_\beta) = c_\beta).$$

Then

$$q|\beta \parallel \beta \bar{g} \text{ uniformizes } \bar{a}^\beta|\theta + 2.$$

Thus $q|\beta$ forces both $(\bar{g} \in Q_\beta)$ and $(\beta \leq q_\beta q(\beta))$, and we can define a condition $r \in P_{\beta+1}$ by $\text{dom}(r) = (\text{dom}(q) \cap \beta \cup \{\beta\}, q|\beta = r|\beta$, and $r(\beta) = \bar{g}$. Then $r \leq \beta + 1 q|\beta + 1$, and hence $s = r \cup q$ is a condition in $P_\alpha$ satisfying the properties required.

Lemma 3.6. The generic colouring $\bar{b}$ satisfies $\parallel_1 \bar{b} \nsubseteq \text{Unif}.$

Proof. Suppose, contrary to the claim, that there are a condition $p \in P_1$ and a $P_1$-name $h$ for a function from $\omega_1$ into $F$ such that $p$ forces $h(\bar{x}) \sim \bar{b}$. Let $M$ be a countable elementary submodel of $\mathcal{N}(p, h)$ such that $M \cap \omega_1$ is an ordinal $\delta \in S$ (such an $M$ exists by an argument similar to that in the proof of Lemma 3.2(b)). Choose two increasing sequences $\langle \epsilon_n \mid n < \omega \rangle$ and $\langle \xi_n \mid n < \omega \rangle$ of ordinals with limit $\delta$. We define by induction on $n < \omega$ conditions $q_n \in P_1 \cap M$ and elements $d_n \in F$ ($F = F \cap M$ since $F$ is finite).

Let $r \in P_1 \cap M$ be such that $r \leq p$ and $\epsilon_0 \leq \text{dom}(r)$. We define $q_0 \in P_1 \cap M$ to be an extension of $r$ which decides the value of $h(\xi_0)$, say $d_0 \in F$ and $q_0 \parallel_1 h(\xi_0) = d_0$. Similarly, if we assume that $q_n$ and $d_n$ are already defined, we let $q_{n+1} \in P_1 \cap M$ and $d_{n+1}$ be such that $\epsilon_{n+1} \leq \text{dom}(q_{n+1})$ and $q_{n+1} \parallel_1 h(\xi_{n+1}) = d_{n+1}$.

Since $q_n \in M$, $\text{dom}(q_n(0)) < \delta$ holds for every $n < \omega$. As pointed out many times before, $q = \bigsqcup_{n < \omega} q_n$ is a condition in $P_1$ which does not yet decide the values of $\bar{x}(\delta)$ or $\bar{b}(\delta)$. These properties, together with Lemma 3.5(a) and the fact that $\langle x_{\xi_n} \mid n < \omega \rangle$ is a ladder on $\delta$, ensure that there is $r \leq q$ in $P_1$ satisfying, for each
n < ω, that r ⊩ 1 \( \overline{x}_{\beta,n} = x_{\xi_n} \) & \( \overline{b}_{\beta,n} = d_n + 1 \). This contradicts the fact that r ≤ p and p ⊩ 1 \( (h(\overline{x}(\delta)) \approx \overline{b}(\delta)) \), since for all n < ω,
\[
r ⊩ 1 \hat{h}(\overline{x}_{\delta,n}) = \hat{h}(\xi_n) = d_n + 1 = \overline{b}_{\delta,n}.
\]

Note that it follows from Lemma 2.3(b) and Lemma 3.6 that after forcing with the first step \( P_1 \) the set \( S \) is still stationary in \( \omega_1 \). An analogous situation also concerns the forthcoming proof of the theorem: we shall show that \( \overline{b} \) is nonuniform after forcing with the whole iteration \( P \); thus the set \( S \) must remain stationary in \( \omega_1 \) (recall that cardinals are preserved by Lemma 3.4(c)).

To prove the theorem it suffices to show that the following holds:

\[ \forall p \quad \text{“} \overline{b} \text{ is nonuniform”} \]

Assume, contrary to this claim, that there exist a \( P \)-generic set \( G \) over \( V \) and in the generic extension \( V[G] \) a uniformizing function \( h : \omega_1 \rightarrow F \) for the colouring \( \overline{b} = \text{int}_G(\overline{b}) \). Since \( \text{card}(h) < \aleph_2 \) we can choose, by Lemma 3.4(a) and Fact 2.4(b), the minimal ordinal \( \alpha^* < \omega_2 \) such that \( h \) is already in \( V[G_{\alpha^*}] \) (\( \alpha^* \geq 2 \) by Lemma 3.6). For the rest of this section, i.e., for the rest of the proof of Theorem 2, let \( \hat{h} \) be a \( P_{\alpha^*} \)-name, and \( p^* \in P_{\alpha^*} \) be a condition such that

\[ (2) \quad p^* \models_{\alpha^*} “\hat{h} \text{ uniformizes } \overline{b}” \]

By assuming this we are aiming at a contradiction. Note that \( G \) is not fixed. To shorten our notation, we abbreviate the set \( \{ p \in P_{\alpha^*} \mid p \leq_{\alpha^*} p^* \} \) by \( P^* \). Purely for technical reasons we assume \( 0 \in \text{dom}(p^*) \).

Although the proof of Lemma 3.6 was simple, it has already revealed the main idea of the forthcoming proof. Namely, we want to contradict (2) by finding an index \( \delta^* \in S \) and condition \( r \) in \( P^* \) which forces \( \hat{h}(\overline{x}(\delta^*)) \neq \overline{b}(\delta^*) \). The next lemma indicates that this is not a trivial task.

**Lemma 3.7.** If \( Y \) is an unbounded subset of \( \text{Vec} \) and \( d \) is an element in \( F \), then there is no single condition \( p \in P^* \) which forces \( \hat{h}(y) \neq d \) for every \( y \in Y \).

**Proof.** Assume such an unbounded set \( Y \) and condition \( p \in P^* \) exist. Let \( M \) be a countable elementary submodel of \( H_{\alpha^*}(p,Y) \) such that \( M \cap \omega_1 = \delta \subseteq S \). Since \( M \) is an elementary submodel, \( Y \cap M \) must be unbounded in \( \delta \). Fix a ladder \( \langle y_n \mid n < \omega \rangle \) on \( \delta \) such that \( y_n \in Y \cap M \) for all \( n < \omega \). Since \( p \in M \) and \( M \cap \omega_1 = \delta \), \( \text{dom}(p(0)) < \delta \). By Lemma 3.5(a) there is \( q \leq p \) in \( P^* \) satisfying, for all \( n < \omega \),
\[
q \models_{\alpha^*} \overline{x}_{\delta,n} = y_n \quad \& \quad \overline{b}_{\delta,n} = d.
\]

Since \( q \leq p \), \( q \) forces \( \hat{h}(\overline{x}_{\delta,n}) \neq \overline{b}_{\delta,n} \), for all \( n < \omega \). This contradicts \( (q \leq p^* \text{ and } p^* \text{ forces } \hat{h}(\overline{x}(\delta)) \approx \overline{b}(\delta)) \). □

Because there is no single condition which decides enough about \( \hat{h} \), we shall use a descending chain \( \langle p_n \mid n < \omega \rangle \) of conditions and a lower bound \( r \) of the chain. Since \( P_{\alpha^*} \), for \( 2 < \alpha < \alpha^* \), are not \( \aleph_1 \)-closed, it is not easy to find a suitable chain and bound. The following lemma, together with Lemma 3.11 and Lemma 3.12, solves this problem. The idea behind the following 3.8, 3.9, 3.10, and 3.11 is similar to the constructions in the proof of [Sh:27, Theorem 1.1].
Before stating the lemmas we fix some notation. Suppose a function \( f \) is \( \bigcup_{k<\omega} p_k \), where \( \langle p_k \mid k<\omega \rangle \) is a descending chain of conditions in \( P^* \). Such a function \( f \) is said to be a \textit{countable union of conditions in} \( P^* \), and, as in Lemma 3.2, \( f \) has \textit{height} \( \epsilon \), where \( \epsilon<\omega_1 \), if

for each \( k<\omega \), \( p_k \) is of height \( <\epsilon \), and

for all \( \alpha \in \text{dom}(f) \) and \( \theta<\epsilon \), there is \( k<\omega \) such that \( \alpha \in \text{dom}(p_k) \) and \( p_k \) is of height \( \geq \theta \).

For all \( \alpha<\alpha^*, \xi<\omega_1 \), and \( c \in F \), we write \( f(\alpha)(\xi)=c \), when there is \( n<\omega \) such that \( p_n(\alpha)(\xi)=c \). So if \( \bar{y}=(y_n \mid n<\omega) \) is a sequence of elements in \( \text{Vec} \), \( \bar{a}=(a_n \mid n<\omega) \) is a sequence of elements in \( F \), and \( \alpha \in \text{dom}(f) \), then \( f(\alpha)(\bar{y})\approx \bar{a} \) means that

\[ \{ n<\omega \mid \text{there is } k<\omega \text{ such that } p_k|\alpha \forces_{\alpha} p_k(\alpha)(y_n)=a_n \} \in D. \]

We write \( f \in p \), where \( p \in P_\alpha \) and \( \alpha \leq \alpha^* \), if \( \text{dom}(f) \subseteq \text{dom}(p) \) and for each \( \beta \in \text{dom}(f) \) the condition \( p|\beta \) forces \( f(\beta) \in p(\beta) \). Note that if \( \alpha \in \text{dom}(f) \) then there is \( n<\omega \) such that \( \alpha \in \text{dom}(p_n) \) and \( p_n|\alpha \not\forces_{\alpha} p_n(\alpha)=1 \). It follows that \( p_n|\alpha \) forces \( Q_\alpha \) to be nontrivial, and hence \( \alpha \) is not \( p_n \)-trivial for any \( m<\omega \).

Let \( \delta^* \) be an ordinal satisfying \( \text{dom}(p^*(0))<\delta^* \in S \), and \( A^* \) a nonempty and countable subset of \( \alpha^* \setminus \{ 0 \} \). Suppose \( \{ 0 \} \cup A^* \) is enumerated by \( \{ \alpha_i \mid i<i^* \} \), where \( 2\leq i^*<\omega_1 \) and \( 0=\alpha_0<\alpha_i<\alpha_j \) for all \( 0<i<j<i^* \).

**Lemma 3.8.** Suppose that \( \bar{y}=(y_n \mid n<\omega) \) is a ladder on \( \delta^* \) and for each \( u : i^* \to \omega F \) there exists a mapping \( f_u \) with the following properties:

a) \( f_u \) is a countable union of conditions in \( P^* \), \( \text{dom}(f_u) \subseteq \{ 0 \} \cup A^* \), and \( f_u \) has height \( \delta^* \);

b) for all \( u,v:i^* \to \omega F \) and \( i<i^* \), if \( u|i=v|i \) then \( f_u|\alpha_i=f_v|\alpha_i \);

c) for every nonzero \( i<i^* \), if \( \alpha_i \in \text{dom}(f_u) \) then \( f_u(\alpha_i)(\bar{y})\approx u(i) \).

Then there are \( u : i^* \to \omega F \) and a condition \( r \in P^* \) such that \( f_u \subseteq r \), i.e., \( r \) is a lower bound for the conditions which form \( f_u \). Moreover, \( r \) forces \( (\bar{a}(\delta^*)=\bar{y}) \) and \( (\bar{b}_{\delta^*},n \neq 0) \) for every \( n<\omega \).

**Proof.** The proof below is directly based on [She77, Lemma 1.7].

First of all we define for each \( u : i^* \to \omega F \) a condition \( r^*_0 \in P_1 \) as follows. By (a), \( f_u \) is a union of conditions and \( \text{dom}(f_u(0))=\delta^* \). Hence, by the definition of \( Q_0 \), \( f_u|\alpha_1=f_u|1 \) is a condition in \( P_1 \) (\( \text{dom}(f_u|\alpha_1)=\{ \alpha_0 \} =\{ 0 \} \)). By Lemma 3.5(a) there is a condition \( r^*_0 \leq f_u|1 \) in \( P_1 \) for which

\[ \bar{a}(\delta^*)=\bar{y} \quad \text{and} \quad \bar{b}_{\delta^*},n = 1, \quad \text{for all } n<\omega. \]

Since \( f_u \) is a union of conditions stronger than \( p^* \), \( r^*_0 \leq p^*|1 \). Clearly, \( f_u|\alpha_1 \in r^*_0 \). Note that, for all \( u,v : i^* \to \omega F \), if \( u|1=v|1 \), then \( f_u|1=f_v|1 \), by (b). Hence we may assume \( r^*_0 \) for all \( u,v \) satisfying \( u|1=v|1 \).

For technical reasons we define \( \alpha_{i^*} \) to be \( \alpha_{(i^*+1)}+1 \) if \( i^* \) is a successor ordinal, and \( \sup \{ \alpha_i \mid i<i^* \} \) otherwise. We prove by induction on \( k \leq i^* \) the following extension property for all \( 1 \leq j<k \leq i^* \):

if \( u : i^* \to \omega F \) and \( p \in P_{\alpha_j} \) satisfy

\[ p|1 \leq r^*_0 \quad \text{and} \quad f_u|\alpha_j \subseteq p, \]

then there are \( v : i^* \to \omega F \) and \( r \in P_{\alpha_k} \) such that

\[ u|j = v|j \quad \text{and} \quad r|\alpha_j \leq \alpha_{j^*} \quad \text{and} \quad f_v|\alpha_k \subseteq r. \]
Suppose first that $1 \leq j < k \leq i^*$, $k$ is a successor ordinal, and $u : i^* \to \omega F$ and $p \in P_{\alpha_j}$ are as required above. Observe that this includes the case $j = 1$ and $k = j + 1 = 2$. We may assume $k = j + 1$, since otherwise there are, by the induction hypothesis, $u'$ extending $u$ and $p'$ such that $u[j] = u'[j]$ and $u'[\alpha_k-1] \in p'$. It suffices to prove the claim for such $u'$ and $p'$.

If $\alpha_j \notin \text{dom}(f_u)$, then $v = u$ and $r = p$ satisfy the claim. Assume $\alpha_j \in \text{dom}(f_u)$. Let $q \leq p$ in $P_{\alpha_j}$ and a sequence $d \in \omega F$ be such that

$$q \models_{\alpha_j} \bar{\alpha}^\omega(\delta^*) = d.$$  

Note that by Lemma 3.3, $d$ is in $V$. Define a function $v : i^* \to \omega F$ for all $i < i^*$ by

$$v(i) = \begin{cases} d & \text{if } i = j; \\ u(i) & \text{otherwise}. \end{cases}$$

Since $v[j] = u[j]$, it follows from (b) that $f_u|\alpha_j = f_u|\alpha_j \in p \geq q$. Let $(p_m \mid m < \omega)$ be a descending chain of conditions exemplifying that $f_u$ is a union of conditions in $P^*$ and $f_u$ has height $\delta^*$. Then $p_m|\alpha_j \models q$ for every $m \in \omega$, and furthermore, for each $\delta \in S \cap \delta^*$ there is $m < \omega$ such that

$$p_m|\alpha_j \models f_u(\alpha_j)(\bar{\delta}(\delta)) = p_m(\alpha_j)(\bar{\delta}(\delta)) \approx \bar{\alpha}^\omega(\delta).$$

By (c), and since $q \leq \alpha_j$, $p_m|\alpha_j$ the set $\{n < \omega \mid f_u(\alpha_j)(y_n) = v(j)(n)\}$ is in $D$. This, together with $q[1 \leq 1 r_0^w, (A),$ and (B), implies that

$$q \models_{\alpha_j} f_u(\alpha_j)(\bar{\delta}(\delta^*)) = f_u(\alpha_j)(\bar{\delta})(\delta) \approx v(j) = d = \bar{\alpha}^\omega(\delta^*).$$

We define $r$ to be $q \cup \{(\alpha_j, f_u(\alpha_j))\}$. Then $r$ is a condition in $P_{\alpha_k}$ satisfying $r|\alpha_j = q \leq \alpha_j p$ and $f_u|\alpha_k \in r$.

The second case is that $k \leq i^*$ is a limit ordinal. Suppose $1 \leq j < k$ and $u$, $p$ satisfy the assumptions of the extension property. Our induction hypothesis is that the extension property holds for all $k' < k$. Let $\mathcal{M}$ be a countable elementary submodel of $H_{\alpha^*}(\delta^*, i^*, \langle \alpha_i \mid i < i^* \rangle, p, u, \langle r_0^w \mid w : i^* \to \omega F \rangle, \langle f_w \mid w : i^* \to \omega F \rangle)$,

such that $\mathcal{M} \cap \omega_1 = \theta \in \omega_1 \setminus S$. We let $\langle \theta_n \mid n < \omega \rangle$ an increasing sequence of ordinals with limit $\theta$, and $\langle j_n \mid n < \omega \rangle$ be an increasing sequence of ordinals with limit $k$, where $j_0 = j$. Note that each $j_n$ is in $\mathcal{M}$, since $i^* < \omega$ and $\mathcal{M} \cap \omega_1$ is an ordinal.

We define by induction on $n < \omega$ conditions $q_n \in P_{\alpha_j} \cap \mathcal{M}$ and functions $u_n : i^* \to \omega F$ in $\mathcal{M}$ as follows. Let $u_0$ be $u$, and let $q_0 \in P_{\alpha_0} \cap \mathcal{M}$ be an extension of $p$ having height greater than $\theta_0$. This is possible by Lemma 3.2(b).

Suppose $u_n \in \mathcal{M}$ and $q_n \in P_{\alpha_j} \cap \mathcal{M}$ are already defined. Suppose also that $q_n$ has height greater than $\theta_j$, $q_n[1 \leq 1 r_0^w, f_u|\alpha_j, u_n|j_m = u_m|j_m$ for every $m < n$. Since $\mathcal{M}$ is an elementary submodel, our induction hypothesis holds in $\mathcal{M}$. Hence there are in $\mathcal{M}$ a function $u_{n+1}$ and $r'$ in $P_{\alpha_{j+1}}$ with $u_{n+1}|j_n = u_n|j_n$, $r'|\alpha_j \leq \alpha_j q_n$, and $f_{u_{n+1}}|\alpha_{j+1} \in r'$. We define $q_{n+1}$ in $P_{\alpha_{j+1}} \cap \mathcal{M}$ to be an extension of $r'$ having height greater than $\theta_{n+1}$. Again, this is possible by Lemma 3.2(b).

Now $q_{n+1}|\alpha_{j_n} \leq \alpha_j q_n$ and $u_{n+1}|j_n = u_n|j_n$ for all $n < \omega$. We define $r$ to be $\bigcup_{n < \omega} q_n$. This is a condition in $P_{\alpha_k}$ by Lemma 3.2(a). We define a function
$v : i^* \to \omega F$ for all $i < i^*$ by

$$v(i) =
\begin{cases}
  u_m(i) & \text{if } i < k, \text{ where } m = \min \{ n < \omega \mid i < j \}; \\
  u(i) & \text{otherwise}.
\end{cases}$$

Then, directly by their definition and (b), $r$ and $v$ satisfy

$$f_v|\alpha_k = \bigsqcup_{n < \omega} f_{u_n}|\alpha_{j_n} \in \bigsqcup_{n < \omega} q_n = r. \quad \square$$

Consequently, there is a lower bound for a certain descending chain of conditions if the functions $f_u, u : i^* \to \omega F$ satisfying the requirements of the preceding lemma exist (remember, $u$ is a union of conditions but not necessarily a condition itself. We shall find those functions as unions of conditions in special kinds of trees. We again need some more notation. Let $\bar{A} = \langle A_m \mid m < \omega \rangle$ be a chain of finite subsets of the set $A^*$ such that $A_m = A^*$ for all $m < \omega$ if $A^*$ is finite, and otherwise $\bar{A}$ is increasing and $A^* = \bigcup_{m < \omega} A_m$. Such a chain $\bar{A}$ is called a filtration of $A^*$. The disjoint union $\bigcup_{i \leq m} A_i \times \{ i \}$, for $m < \omega$, is abbreviated by $A_{\leq m}$. For $m < \omega$, $A_{\leq m} \cap \alpha$ is a shorthand for the set $\bigcup_{i \leq m} (A_i \cap \alpha) \times \{ i \}$, and for a function $\eta$ having the domain $A_{\leq m}$, $\eta|\alpha$ is a shorthand for the restriction $\eta(A_{\leq m} \cap \alpha)$.

**Definition 3.9.** Suppose $m < \omega$. We set

$$\text{Ind}(A_{\leq m}) = \{ \eta \mid \eta \text{ is a function from } A_{\leq m} \text{ into } F \}.$$ 

An $A_{\leq m}$-condition tree $T$ is a mapping from $\text{Ind}(A_{\leq m})$ into $P^*$ with the property that for all $\eta, \nu \in \text{Ind}(A_{\leq m})$ and $\alpha \in A_m$,

$$\eta|\alpha = \nu|\alpha \text{ implies } T(\eta)|\alpha = T(\nu)|\alpha.$$ 

Sometimes we abbreviate $T(\eta)$ by $T_\eta$.

Suppose $n \leq m < \omega$. An $A_{\leq m}$-condition tree $T$ is stronger than an $A_{\leq n}$-condition tree $R$, in symbols $T \leq R$, if for each $\eta \in \text{Ind}(A_{\leq m})$ we have $T(\eta) \leq_{n*} R(\eta|A_{\leq n})$.

An $A_{\leq m}$-condition tree $T$ is of height $\geq \epsilon$, $\epsilon < \omega_1$, if all the conditions in $T$ are of height $\geq \epsilon$. The notion “$T$ has height $< \epsilon$” is defined analogously.

**Definition 3.10.** Suppose $\bar{A}$ is a filtration of $A^*$, $\bar{y}$ is a ladder on $\delta^*$, and $\bar{\epsilon}$ is an increasing sequence of ordinals with limit $\delta^*$. An $(\bar{\epsilon}, \bar{y})$-tree system on $\bar{A}$ is a family $\bar{T} = \langle T^m \mid m < \omega \rangle$ of functions fulfilling the following requirements for each $m < \omega$:

a) $T^m$ is an $A_{\leq m}$-condition tree;

b) for all $\eta \in \text{Ind}(A_{\leq m})$, $\text{dom}(T^m_\eta) \subseteq \{ 0 \} \cup A^*$ (where $A^* = \bigcup_{m < \omega} A_m$);

c) for all $\eta \in \text{Ind}(A_{\leq m})$ and $\alpha \in A_m$, $\alpha$ is $T^m_\eta$-trivial or $T^m_\eta(\alpha)(y_m) = \eta(\alpha, m)$;

d) $T^m$ is of height $\geq \epsilon_m$ and $< \delta^* (= \sup \bar{\epsilon})$;

e) $T^m \geq T^{m+1}$.

Recall that we assume $\alpha \in \text{dom}(T^m_\eta)$ and $T^m_\eta|\alpha \models_\alpha \text{supp}(y_m) \in \text{dom}(T^m_\eta|\alpha)$ when we write $T^m_\eta(\alpha)(y_m) = \eta(\alpha, m)$.

**Lemma 3.11.** For each $(\bar{\epsilon}, \bar{y})$-tree system $\bar{T}$ on $\bar{A}$ there are indices $\eta^m \in \text{Ind}(A_{\leq m})$, $m < \omega$, such that $(T^m_\eta(y^m))|m < \omega$ is a descending chain of conditions having a lower bound $r \in P^*$. Moreover, $r$ forces $(\bar{x}(\delta^*) = \bar{y})$ and, for all $n < \omega$, $\bar{b}_{\delta^*, n} \neq 0$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Proof. The idea of the following proof is similar to [She77, Lemma 1.8]. Recall that 
\{\alpha_i \mid i < i^*\} is an increasing enumeration of \{0\} ∪ A^*.

For all \( m <\omega \) and \( u : i^* \to \omega \) we define the index \( \eta_u^m \in \text{Ind}(A_{\leq m}) \) by setting, for all \( (\alpha, n) \in A_{\leq m} \),
\[
\eta_u^m(\alpha, n) = u(i)(n),
\]
where \( i < i^* \) is the index with \( \alpha = \alpha_i \). We set
\[
f_u = \bigsqcup_{m < \omega} T^m(\eta_u^m).
\]
Now, if \( f_u \) were as required in Lemma 3.8 and \( T^m(\eta_u^m) \geq T^{m+1}(\eta_u^{m+1}) \) for every \( m < \omega \), then it would follow, by the same lemma, that there are some \( u \) and \( r \in P^* \) such that \( f_u \subseteq r \) and \( r \) forces \( (\bar{x}(\delta^*) = \bar{y}) \) and \( (\bar{b}_{i^*, n} \neq 0) \) for all \( n < \omega \). By the definition of \( f_u \), \( r \) would be a lower bound of the descending chain \( \langle T^m(\eta_u^m) \mid m < \omega \rangle \) of conditions. So to prove the claim it suffices to check that the conditions \( T^m(\eta_u^m), m < \omega \), form a descending chain of conditions and \( f_u \) satisfies the properties wanted in Lemma 3.8.

(a) The function \( f_u \) is well-defined since, for all \( i \) and \( n \) such that \( (\alpha_i, n) \in A_{\leq m} \),
\[
\eta_u^m(\alpha_i, n) = u(i)(n) = \eta_u^{m+1}(\alpha_i, n),
\]
i.e., \( \eta_u^m = \eta_u^{m+1}|_{A_{\leq m}} \), and so by Definition 3.10(e), \( T^m(\eta_u^m) \geq T^{m+1}(\eta_u^{m+1}) \). For each \( u : i^* \to \omega \) such that \( \text{dom}(f_u) \subseteq \{0\} \cup A^* \) by Definition 3.10(b), and \( f_u \) has height \( \delta^* \) by Definition 3.10(d).

(b) Suppose \( u, v : i^* \to \omega \), \( 0 < i < i^* \), and \( u[i = v[i] \). For all \( m < \omega \) and \( (\alpha, n) \in A_{\leq m} \cap \alpha_i, \alpha \) must be \( \alpha_j \) for some \( j < i \) since \( \alpha < \alpha_i \), and furthermore,
\[
\eta_u^m(\alpha_j, n) = u(j)(n) = v(j)(n) = \eta_v^m(\alpha_j, n).
\]
Thus for each \( m < \omega \), \( \eta_u^m|_{\alpha_i} = \eta_v^m|_{\alpha_i} \), and by Definition 3.10(a), \( T^m(\eta_u^m)|_{\alpha_i} = T^m(\eta_v^m)|_{\alpha_i} \). Consequently, for all \( \beta \in \text{dom}(f_u) \cap \alpha_i = \text{dom}(f_v) \cap \alpha_i \),
\[
\|_{\beta} f_u(\beta) = \bigsqcup_{m < \omega} T^m(\eta_u^m)(\beta) = \bigsqcup_{m < \omega} T^m(\eta_v^m)(\beta) = f_v(\beta),
\]
and we may assume \( f_u(\beta) \) is the same name as \( f_v(\beta) \), i.e., \( f_u|_{\alpha_i} = f_v|_{\alpha_i} \).

(c) Let \( u : i^* \to \omega \) and \( i < i^* \) be such that \( \alpha_i \in \text{dom}(f_u) \). Then \( \alpha_i \) is not \( T^m(\eta_u^m) \)-trivial for any \( m < \omega \). Let \( n < \omega \) be such that \( \alpha_i \in A_n \). Then for each \( m \geq n \) we have \( \alpha_i \in A_m \), and, by Definition 3.10(c),
\[
f_u(\alpha_i)(y_m) = T^m(\eta_u^m)(\alpha_i)(y_m) = \eta_u^m(\alpha_i, m) = u(i)(m).
\]

Now the main problem to be solved is the existence of a tree system where each condition tree decides enough information about the uniformizing function \( h \).

Lemma 3.12. There exist a countable subset \( A^* \) of \( \alpha^* \times \{0\} \), a filtration \( \tilde{A} \) of \( A^* \), \( \delta^* \in S \), an increasing sequence \( \bar{c} \) of ordinals with limit \( \delta^* \), a ladder \( \bar{y} \) on \( \delta^* \), and an \((\bar{c}, \bar{y})\)-tree system \( \tilde{T} \) on \( \tilde{A} \) such that, for all \( m < \omega \) and \( \eta \in \text{Ind}(A_{\leq m}) \),
\[
T^m_{\eta} \models \bar{x}(\delta^*, m) = y_m \land \bar{b}_{i^*, m} \neq 0, \text{ for all } m < \omega.
\]
On the other hand, Lemma 3.12 ensures that the lower bound \( r \) also satisfies the following condition:

\[
    r \models_{\alpha^*} h(y_m) = 0, \text{ for all } m < \omega.
\]

It follows that \( r \leq_{\alpha^*} p^*, \delta^* \in S, \) and \( r \models_{\alpha^*} (h(x(\delta^*)) \neq \bar{b}(\delta^*)), \) contrary to our assumption \((\bar{2})\). So, to prove Theorem 2 it suffices to show that Lemma 3.12 holds. To achieve this goal we have to analyze the relation between the values of conditions and the value of \( h \) in detail. Therefore we shall delay the proof of Lemma 3.12 until the end of this subsection.

The following is a strengthening of Lemma 3.7.

**Lemma 3.13.** Suppose \( \alpha < \alpha^* \), \( d \in F \), \( Y \) is an unbounded subset of Vec, \( p \in P^* \), and \( H \) is a \( P_{\alpha^*} \)-generic set over \( V \) containing \( p|_{\alpha} \). Then there are an unbounded subset \( Z \) of \( Y \) and for every \( z \in Z \) a condition \( q^z \in P^* \) satisfying

\[
    q^z \leq_{\alpha^*} p, \\
    q^z|_{\alpha} \models \alpha \in H, \\
    q^z \models_{\alpha^*} h(z) = d.
\]

**Proof.** Suppose the lemma fails, and fix \( \alpha, p, d, Y, \) and \( H \). Recall what Fact 2.5 asserts, and note that in \( V[H] \) the condition \( p \) belongs to \( P_{\alpha^*} \). Consider the set \( Y \) and \( p \) in \( V[H] \). By our assumption, for all unbounded \( Z \subseteq Y \) there must be some \( z \in Z \) such that

for all \( s \in P^* \), if \( s|_{\alpha} \in H \) and \( s \leq_{\alpha^*} p \) then \( s \not\models_{\alpha^*} h(z) = d \).

Directly by Fact 2.5(b), the following holds in \( V[H] \):

for all \( r \in P_{\alpha^*} \), if \( r \leq_{\alpha^*} p \) then \( r \not\models_{\alpha^*} h(z) = d \).

Hence, for all sets \( Z_0 = \{ y \in Y \mid \theta < \min(\text{supp}(y)) \} \), where \( \theta < \omega_1 \), there is \( z_0 \in Z_0 \) such that in \( V[H] \), for every \( r \leq_{\alpha^*} p \) in \( P_{\alpha^*} \), there is a condition \( t \leq_{\alpha^*} r \) in \( P_{\alpha^*} \) for which \( t \models_{\alpha^*} h(z_0) \neq d \). This means that in \( V[H] \) the collection of those conditions which forces \( (h(z_0) \neq d) \) is dense below \( p \) in the sense of \( P_{\alpha^*} \). Thus, in \( V[H] \), \( p \models_{\alpha^*} (h(z_0) \neq d) \) for all \( \theta < \omega_1 \). By Fact 2.5(b) there is \( s \leq_{\alpha^*} p \) in \( P^* \) forcing \( (h(z_0) \neq d) \), for all \( \theta < \omega_1 \). This contradicts Lemma 3.7. \( \square \)

**Definition 3.14.** For all nonzero \( \alpha < \alpha^* \) and \( p \in P^* \) we define \( \text{Pos}_{\alpha^*}(p) \) to be the set of tuples \( (c_0, d_0, c_1, d_1) \in F^4 \) satisfying the following requirement. There are an unbounded subset \( Y \) of Vec, and for each \( y \in Y \) conditions \( q_i^y \leq_{\alpha^*} p \) in \( P^* \), \( i = 0, 1 \), such that

a) \( q_0^y|_{\alpha} = q_1^y|_{\alpha}; \)

b) either \( \alpha \) is both \( q_0^y \)-trivial and \( q_1^y \)-trivial, or \( q_i^y(\alpha)(y) = c_i \) for both \( i = 0 \) and \( 1 \);

c) \( q_i^y \models_{\alpha^*} h(y) = d_i \) for both \( i = 0 \) and \( i = 1 \).

In the following lemma, the property (c) will be the principal one later on.

**Lemma 3.15.**

a) If \( p \in P^* \) and nonzero \( \alpha < \alpha^* \) are such that there is \( q \leq_{\alpha^*} p \) in \( P^* \) for which \( \alpha \) is \( q \)-trivial, then \( (c, d_0, c_1, d_1) \in \text{Pos}_{\alpha^*}(p) \) for all \( c, d_0, d_1 \in F \).

b) If \( \alpha < \alpha^* \) nonzero, \( p \in P^* \), and \( (c_0, d_0, c_1, d_1) \in \text{Pos}_{\alpha^*}(p) \), where \( c_0 \neq c_1, d \in F \), then there are \( c, d_0 \neq d_1 \in F \) such that \( (c, d_0, c, d_1) \in \text{Pos}_{\alpha^*}(p) \).

c) For all \( p \in P^* \) and nonzero \( \alpha < \alpha^* \), there are \( c, d_0 \neq d_1 \in F \) such that \( (c, d_0, c, d_1) \in \text{Pos}_{\alpha^*}(p) \).
Proof. a) Let $H$ be a $P_{\alpha}$-generic set over $V$ containing $q|\alpha$. By Lemma 3.13 there are an unbounded subset $Y$ of $\text{Vec}$ and conditions $\langle q^y_0 \mid y \in Y \rangle$ in $P^*$ such that for every $y \in Y$,

$$
q^y_0 \leq q, \\
q^y_0|\alpha \in H, \\
q^y_0 \forces_{\alpha^*} \dot{h}(y) = d_0.
$$

By the same lemma there are an unbounded subset $Z$ of $Y$ and conditions $\langle q^y_1 \mid y \in Z \rangle$ in $P^*$ such that

$$
q^y_1 \leq q, \\
q^y_1|\alpha \in H, \\
q^y_1 \forces_{\alpha^*} \dot{h}(y) = d_1.
$$

By Fact 2.6 there are, for $y \in Z$ and $i = 0, 1$, $r^y_i \leq q^y_i$ in $P^*$ such that $r^y_0|\alpha = r^y_1|\alpha$. Then for all $c \in F$, the unbounded subset $Z$ of $\text{Vec}$ and the conditions $\langle r^y_i \mid i = 0, 1 \rangle$ exemplify that $(c, d_0, c, d_1) \in \text{Pos}_a(q) \in \text{Pos}_a(p)$. Observe that $\alpha$ is $r^y_i$-trivial for $i = 0, 1$.

For the rest of the proof, we can restrict ourselves to the case that $p|\alpha$ forces $\dot{Q}_\alpha$ to be nontrivial by (a).

b) Suppose an unbounded subset $Y$ of $\text{Vec}$ and conditions $q^y_0, q^y_1 \leq p$ for $y \in Y$ exemplify that $(c_0, d, c_1, d) \in \text{Pos}_a(p)$. By the nontriviality of $\alpha$ we assume that for $i = 0, 1$ and $y \in Y$,

$$
q^y_i|\alpha = q^y_i|\alpha, \\
q^y_i(\alpha)(y) = c_i, \\
q^y_i \forces_{\alpha^*} \dot{h}(y) = d.
$$

Consider some $y \in Y$ and $q^y_0$. Let $H$ be a $P_{\alpha}$-generic set over $V$ such that $q^y_0|\alpha = q^y_1|\alpha \in H$. By Lemma 3.13 there must be an unbounded subset $Z^y_0$ of $\text{Vec}$ satisfying for all $z \in Z^y_0 = \text{Pos}_a(q)$ in $P^*$ such that $r^y_{0,z} \leq q^y_0, r^y_{1,z}|\alpha \in H$, and $r^y_{0,z} \forces_{\alpha^*} \dot{h}(z) = 0$. Since $Z^y_0$ is unbounded, we can use the same lemma again. Hence there must be some $z^y \in Z^y_0$ and a condition $r^y_{1,z^y} \leq q^y_1$ in $P^*$ such that $r^y_{1,z^y}|\alpha \in H$, and $r^y_{1,z^y} \forces_{\alpha^*} \dot{h}(z^y) = 1$. By Fact 2.6 there are in $P^*$ conditions $s^y_i \leq r^y_{1,z^y}$ for $i = 0, 1$ such that $s^y_0|\alpha = s^y_1|\alpha$.

By Lemma 3.5(b), we may assume that $\text{dom}(z^y) \subseteq \text{dom}(s^y_i(\alpha))$ for $i = 0, 1$. Since $F$ is countable and $Y$ is uncountable, there are an unbounded subset $Z$ of $Y$ and $(a_0, a_1) \in F^2$ such that the pair $(s^y_0(\alpha)(z^y), s^y_1(\alpha)(z^y))$ is $(a_0, a_1)$ for every $y \in Z$.

Define $e_0 = a_1 - a_0$ and $e_1 = c_0 - c_1$. Since $c_0 \neq c_1$, $e_1$ is not 0 ($e_0$ might be 0).

Now, for all $i = 0, 1$ and $y \in Z$ the following hold:

$$
s^y_i(\alpha)(e_0 y + e_1 z^y) = e_0 c_i + e_1 a_i, \\
s^y_i \forces_{\alpha^*} \dot{h}(e_0 y + e_1 z^y) = e_0 d + e_1 i.
$$

Consequently, the unbounded subset $\{(e_0 y + e_1 z^y) \mid y \in Z\}$ of $\text{Vec}$ and the conditions $s^y_i$, for $i = 0, 1$ and $y \in Z$, exemplify that $(c, d_0, c, d_1) \in \text{Pos}_a(p)$, where $c = e_0 c_0 + e_1 a_0 (= e_0 c_1 + e_1 a_1), d_0 = e_0 d + e_1 0$, and $d_1 = e_0 d + e_1 1$. Clearly, $d_0 \neq d_1$.

c) We may assume that $p|\alpha$ decides the value of $\text{dom}(p(\alpha))$. Suppose, contrary to the claim, that there are no elements $c, d_0 \neq d_1$ in $F$ such that $(c, d_0, c, d_1) \in$
Pos_α(p). By (b) this implies that there are no \( c_0 \neq c_1, d \in F \) satisfying \((c_0, d, c_1, d) \in \text{Pos}_α(p)\) either.

Let \( H \) be a \( P_\alpha \)-generic set over \( V \) such that \( p|α ∈ H \). Define \( \text{Pos}_H(p) \) to be the set of all \((ξ, c, d) ∈ ω_1 \times F \times F \) such that there is \( q ∈ P^* \) satisfying the following requirements:

\[
\begin{align*}
q &≤_α p, \\
q|α &∈ H, \\
q(α)(ξ) &∈ c, \\
q(\hat{r}|_α) &∈ d.
\end{align*}
\]

It is easy to see, using Fact 2.5, that for all \( ξ < ω_1 \) satisfying \( ξ \not∈ \text{dom}(p(α)) \), and \( c ∈ F \), there is \( d ∈ F \) such that \((ξ, c, d) ∈ \text{Pos}_H(p)\). Namely, by Lemma 3.5(b) there is \( q ≤ p \) for which \( q(α)(ξ) = c \) and \( q|α = p|α ∈ H \). Since \( q|α ∈ H \) and \( q(\hat{r}|_α) ∈ H \), the following holds in \( V[H] \) by Fact 2.5(a): there are \( r ≤ q \) in \( P_\alpha \) and \( d ∈ F \) for which \( r|_α \) is a line. Using this assumption, \( d \) is a limit such that \( \text{Pos}_H(p) \) is always nonempty.

Another easy property is that if there are an unboundedly many \( I \) of \( ω_1 \) and \( (c_0, d_0, d_1) ∈ F \) such that for every \( ξ ∈ I \) both \((ξ, c_0, d_0) \) and \((ξ, c_1, d_1) \) are in \( \text{Pos}_H(p) \), then \((c_0, d_0, c_1, d_1) \) is in \( \text{Pos}_α(p) \). Namely, if for \( ξ ∈ I \) the conditions \( \pi_ξ(c) = d \) and \( \pi_ξ(c_1) = d_1 \) are in \( \text{Pos}_α(p) \), then \( (c_0, d_0, c_1, d_1) \) is in \( \text{Pos}_α(p) \). Observe that these two simple observations together imply that \( \text{Pos}_α(p) \) is always nonempty.

It follows from our initial assumptions that we can fix \( μ' < ω_1 \) such that the definition

\[
\pi_ξ(c) = d \quad \text{iff} \quad (ξ, c, d) ∈ \text{Pos}_H(p)
\]

yields in \( V[H] \) an injective function \( \pi_ξ : F → F \) when \( μ' ≤ ξ < ω_1 \). Since \( F \) is finite, each \( π_ξ \) is in fact a permutation of \( F \). From the definition of \( \text{Pos}_H(p) \) it follows that \( p|_α \) is a line if there are \( k, m ∈ F \) such that \( π_ξ(a) = ka + m \) for all \( a ∈ F \) (for all \( a ∈ F \) is the slope of the line).

Our proof of (c) will have the following structure.

1) First we assume that there are unboundedly many \( ξ < ω_1 \) such that \( π_ξ \) is not a line. It will follow that there are \( c, d_0 ≠ d_1 ∈ F \) such that \((c, d_0, c, d_1) \in \text{Pos}_α(p)\), contrary to our initial assumption.

2) We assume the converse of (1), i.e., we suppose \( μ < ω_1 \) is a limit such that \( μ' ≤ μ \) and, for every \( μ ≤ ξ < ω_1 \),

(A) \( k_ξ \) and \( m_ξ \) are elements in \( F \) such that \( π_ξ(a) = k_ξa + m_ξ \) holds for all \( a ∈ F \) in \( V[H] \).

Since each \( π_ξ \) is injective, \( k_ξ ≠ 0 \) for every \( μ ≤ ξ < ω_1 \). Using this assumption, we shall make two more steps.

i) We show that \( (B) \) there are no \( θ < ω_1 \) and \( e ∈ F \) such that \( k_ξ = e \) whenever \( \max \{θ, μ\} ≤ ξ < ω_1 \).
Observe that this is the only part of the proof of the theorem where the condition (\(\vec{a}^* \not\in (\vec{b} + \text{Unif})\)) in Definition 3.1 is essential, i.e., that we do not “kill” colourings which are too “close” to the generic colouring \(\vec{b}\).

ii) The last case is that for all \(\xi \geq \mu\) there is \(\zeta > \xi\) such that \(k_\xi \neq k_\zeta\), i.e., the slopes of lines \(\pi_\xi, \pi_\zeta\) are different. This will yield that there are \(c_0 \neq c_1, d \in F\) such that \((c_0, d, c_1, d) \in \text{Pos}_\alpha(p)\), contrary to our initial assumption.

1) We shall show that for each \(\theta < \omega_1\) there are \(y^\theta \in \text{Vec}\), conditions \(q^\theta, r^\theta \leq p\) in \(P^*\), and elements \(c^\theta, d^\theta \neq c^\theta\) in \(F\) such that \(\min(\text{supp}(y^\theta)) > \theta\) and

\[
q^\theta|\alpha = r^\theta|\alpha, \\
q^\theta(\alpha)(y^\theta) = c^\theta = r^\theta(\alpha)(y^\theta), \\
q^\theta \Vdash_\alpha \vec{h}(y^\theta) = d^\theta, \\
r^\theta \Vdash_\alpha \vec{h}(y^\theta) = c^\theta.
\]

Since the choice of \(\theta\) will be arbitrary, it will follow that there are uncountable \(I \subseteq \omega_1\) and \(c, d \neq e \in F\) such that for every \(\theta \in I\) we have \(c^\theta = c, d^\theta = d\), and \(c^\theta = e\). Then the unbounded subset \(\{y^\theta \mid \theta \in I\}\) of \(\text{Vec}\) and the conditions \(\langle q^\theta, r^\theta \mid \theta \in I\rangle\) will exemplify that \((c, d, c, c)\) is in \(\text{Pos}_\alpha(p)\), where \(d \neq e\), contrary to our initial assumption.

Let \(\theta < \omega_1\) be given. Since there are uncountably many \(\xi < \omega_1\) for which \(\pi_\xi\) is not a line and only finitely many permutations of \(F\), fix \(\xi < \zeta < \omega_1\) such that \(\max \{\mu'(\theta, \text{dom}(p(\alpha)))\} < \xi\) and \(\pi_\xi = \pi_\zeta\) is not a line. Let \(\pi\) be the function \(\pi_\xi = \pi_\zeta\). Fix arbitrary \(a \neq b_0 \in F\), and let \(\psi_0\) be the line satisfying \(\psi_0(a) = \pi(a)\) and \(\psi_0(b_0) = \pi(b_0)\). Since \(\pi_\xi\) is not a line, there is \(b_1 \in F\) for which \(\pi(b_1) \neq \psi_0(b_1)\).

Let \(\psi_1\) be the line for which \(\psi_1(a) = \pi(a)\) and \(\psi_1(b_1) = \pi(b_1)\).

By Lemma 3.5(b) and since \(p|\alpha\) forces \((Q_\alpha = \text{Uf}(\vec{a}^*))\), there is a condition \(q^\theta \in P^*\) such that

\[
p|\alpha = q^\theta|\alpha, \\
q^\theta \leq p, \\
q^\theta(\alpha)(\xi) = a = q^\theta(\alpha)(\zeta).
\]

By the same lemma again, there is \(r^\theta \in P^*\) such that

\[
p|\alpha = r^\theta|\alpha, \\
r^\theta \leq p, \\
r^\theta(\alpha)(\xi) = b_0 \text{ and } r^\theta(\alpha)(\zeta) = b_1.
\]

Hence \(q^\theta|\alpha = r^\theta|\alpha \in H\). From the definition of \(\pi_\xi\) and \(\pi_\zeta\) it follows that

\[
q^\theta \Vdash_\alpha (\vec{h}(\xi) = \pi_\xi(q^\theta(\alpha)(\xi))) = \psi_0(a) \text{ and } \vec{h}(\zeta) = \pi_\zeta(q^\theta(\alpha)(\zeta)) = \psi_1(a).
\]

(A proof of this fact is a reasoning concerning \(\Vdash_{\alpha^*}\) and \(\Vdash_{\alpha, \alpha^*}\) similar to what we have done many times earlier.) Analogously, \(r^\theta\) satisfies

\[
r^\theta \Vdash_\alpha (\vec{h}(\xi) = \psi_0(b_0) \text{ and } \vec{h}(\zeta) = \psi_1(b_1)).
\]

Define \(e_0 = b_1 - a\) and \(e_1 = a - b_0\). Since \(a \neq b_0\) and \(a \neq b_1\) both \(e_0\) and \(e_1\) are nonzero. Define \(y^\theta = (e_0 x \xi + e_1 x \zeta)\) and \(a^\theta = e_0 a + e_1 a = e_0 \psi_0 b_0 + e_1 \psi_0 b_1\). Then

\[
q^\theta(\alpha)(y^\theta) = e_0 a + e_1 a = a^\theta = e_0 \psi_0 b_0 + e_1 \psi_0 b_1 = r^\theta(\alpha)(y^\theta).
\]
Moreover,
\[ q^\theta \models \alpha \cdot \bar{h}(y^\theta) = e_0\bar{h}(\xi) + e_1\bar{h}(\zeta) = e_0\psi_0(a) + e_1\psi_1(a), \]
and
\[ r^\theta \models \alpha \cdot \bar{h}(y^\theta) = e_0\bar{h}(\xi) + e_1\bar{h}(\zeta) = e_0\psi_0(b_0) + e_1\psi_1(b_1). \]
Define \( d^\theta = e_0\psi_0(a) + e_1\psi_1(a) \) and \( e^\theta = e_0\psi_0(b_0) + e_1\psi_1(b_1) \). Then \( d^\theta \neq e^\theta \). Namely, if they are equal then
\[ e_0\psi_0(a) + e_1\psi_1(a) = e_0\psi_0(b_0) + e_1\psi_1(b_1) \]
implies
\[ e_0k_0(a - b_0) = e_1k_1(b_1 - a), \]
where \( k_0 \) and \( k_1 \) are the slopes of the lines \( \psi_0 \) and \( \psi_1 \) respectively (i.e., for \( i = 0, 1 \) we assume \( \psi_i(a') = k_ia' + m_i \) for all \( a' \in F \)). But from the choice of the lines \( \psi_i \) it follows that \( k_0 \neq k_1 \). Hence the preceding equation contradicts our choice of \( e_0 \) and \( e_1 \).

2.i) Suppose \( K \) is a \( P_{\alpha,\alpha^*} \)-generic set over \( V[H] \) satisfying \( p \in K \) and for the elements \( h = \text{int}_K(\bar{h}) \) and \( g_\alpha = \text{int}_K(\bar{g}_\alpha) \), where the names \( h \) and \( \bar{g}_\alpha \) are given in Fact 2.5, the equations \( h(\xi) = \pi_\xi(g_\alpha(\xi)) \) for all \( \mu \leq \xi < \omega_1 \) hold in \( V[H][K] \).

A proof of (B) follows. Fix, contrary to the claim, \( \theta \geq \mu \) and \( e \) satisfying (B). Define in \( V[H] \) a function \( f : \omega_1 \to F \) for all \( \xi < \omega_1 \) by
\[ f(\xi) = \begin{cases} 0 & \text{if } \xi < \theta; \\ \pi_\xi(0) & \text{otherwise.} \end{cases} \]

Then \( f \) satisfies in \( V[H] \) the following equation for all \( a \in F \) and \( \theta \leq \xi < \omega_1 \):
\[ f(\xi) = \pi_\xi(0) = m_\xi = (ea + m_\xi) - ea = \pi_\xi(a) - ea. \]

Hence, independently of what \( g_\alpha \) is, the following equation holds in \( V[H][K] \) for all \( \delta \in S \) and for almost all \( n < \omega \):
\[ b_{\delta,n} - e \cdot a_{\delta,n}^\alpha = h(\mathbf{x}_{\delta,n}) - e \cdot g_\alpha(\mathbf{x}_{\delta,n}) = \left( \sum_{\xi < \delta} e_{\xi,n} \cdot h(\xi) \right) - e \cdot \left( \sum_{\xi < \delta} e_{\xi,n} \cdot g_\alpha(\xi) \right) = \sum_{\xi < \delta} \left( e_{\xi,n} \cdot (h(\xi) - e \cdot g_\alpha(\xi)) \right) = \sum_{\xi < \delta} \left( e_{\xi,n} \cdot (\pi_\xi(g_\alpha(\xi)) - e \cdot g_\alpha(\xi)) \right) = \sum_{\xi < \delta} e_{\xi,n} \cdot f(\xi), \]
where each \( \mathbf{x}_{\delta,n} \) is assumed to be of the form \( \sum_{\xi < \delta} e_{\xi,n}^\alpha x_\xi \).

But \( f \) is already in \( V[H] \). So, from Lemma 2.3(c) it follows that \( b \sim e \cdot a^\alpha \), and hence, \( (a^\alpha \in (b) + \text{Unif}) \) holds in \( V[H] \). By Definition 3.1, \( \text{int}_H(\bar{Q}_\alpha) \) must be \( \{1\} \). Since \( p|\alpha \in H \), this contradicts our initial assumption that \( p|\alpha \) forces \( \bar{Q}_\alpha \) to be nontrivial.

2.ii) If the size of \( F \) is 2, then for every \( \mu \leq \xi < \omega_1 \) the value of \( k_\xi \) must be constantly 1, contradicting (B). Hence the lemma holds if \( F \) is of size 2.

Now, \( \text{card}(F) > 2 \), (A) holds, and \( k_\xi \neq 0 \) for all \( \mu < \xi < \omega_1 \). Analogously to the case (1), to prove that there are \( c \neq e, d \in F \) for which \( (c, d, c, d) \in \text{Pos}_\alpha(p) \), it
suffices to show for arbitrary \( \theta < \omega_1 \) the existence of \( y^\theta \in \text{Vec}, \) and conditions \( q^\theta, r^\theta \) in \( P^* \) satisfying

\[
\begin{align*}
\min(\text{supp}(y^\theta)) > \theta, \\
q^\theta, r^\theta \leq p, \\
q^\theta | \alpha = r^\theta | \alpha, \\
q^\theta(\alpha)(y^\theta) = e^\theta, \\
r^\theta(\alpha)(y^\theta) = e^\theta, \\
q^\theta | \alpha \cdot \hat{h}(y^\theta) = d^\theta, \\
r^\theta | \alpha \cdot \hat{h}(y^\theta) = d^\theta.
\end{align*}
\]

Let \( \theta < \omega_1 \) be given. Fix \( \xi > \max \{ \mu, \theta, \text{dom}(p(\alpha)) \} \) and \( \zeta > \xi \) such that \( k_\xi \neq k_\zeta. \) As in (1) fix \( q^\theta, r^\theta \leq p \) such that

\[
q^\theta | \alpha = r^\theta | \alpha \in H, \\
q^\theta(\alpha)(\xi) = 1 \quad \text{and} \quad q^\theta(\alpha)(\zeta) = 1, \\
r^\theta(\alpha)(\xi) = 2 \quad \text{and} \quad r^\theta(\alpha)(\zeta) = 2.
\]

Define \( e_\xi = -k_\xi \) and \( e_\zeta = k_\zeta. \) Then \( e_\xi k_\xi + e_\zeta k_\zeta = 0, \) and \( e_\xi + e_\zeta \neq 0, \) since \( k_\xi \neq k_\zeta. \) If we let \( y^\theta \) be \( (e_\xi x_\xi + e_\zeta x_\zeta), \) then

\[
q^\theta(\alpha)(y^\theta) = e_\xi \cdot q^\theta(\alpha)(\xi) + e_\zeta \cdot q^\theta(\alpha)(\zeta) = e_\xi + e_\zeta,
\]

and

\[
q^\theta | \alpha \cdot \hat{h}(y^\theta) = e_\xi \cdot (k_\xi + m_\xi) + e_\zeta \cdot (k_\zeta + m_\zeta) = (e_\xi k_\xi + e_\zeta k_\zeta) + (e_\xi m_\xi + e_\zeta m_\zeta) = (e_\xi m_\xi + e_\zeta m_\zeta).
\]

By a similar reasoning \( r^\theta \) satisfies

\[
\begin{align*}
r^\theta(\alpha)(y^\theta) &= 2(e_\xi + e_\zeta), \\
r^\theta | \alpha \cdot \hat{h}(y^\theta) &= 2(e_\xi k_\xi + e_\zeta k_\zeta) + (e_\xi m_\xi + e_\zeta m_\zeta) = (e_\xi m_\xi + e_\zeta m_\zeta).
\end{align*}
\]

Hence \( e^\theta = e_\xi + e_\zeta (\neq 0), \) \( e^\theta = 2e^\theta (\neq e^\theta), \) and \( d^\theta = e_\xi m_\xi + e_\zeta m_\zeta \) are the desired elements of \( F. \)

Now we can proceed with analyzing properties of condition trees. Recall that \( \hat{A} \) is a filtration of \( A^*. \) Suppose \( m < \omega, \) \( T \) is an \( A_{\leq m} \)-condition tree, \( \eta \in \text{Ind}(A_{\leq m}), \) and \( p \) is a condition in \( P^* \) such that \( p|\gamma \leq T(\eta)|\gamma \) for \( \gamma = \max \text{Ind}(A_{\leq m}). \) We define a function \( T[\eta/p] \) by setting, for all \( \nu \in \text{Ind}(A_{\leq m}), \)

\[
T[\eta/p](\nu) = \begin{cases} 
p & \text{if } \nu = \eta; \\
p|\beta_\nu \sqcup T(\nu) & \text{otherwise};
\end{cases}
\]

where \( \beta_\nu = \max \{ \gamma \in A_m \mid \nu|\gamma = \eta|\gamma \}. \) Observe that for each \( \nu \in \text{Ind}(A_{\leq m}), \) \( T[\eta/p](\nu) \) is a condition in \( P^* \) since \( p|\beta_\nu \leq T_\eta|\beta_\nu = T_\nu|\beta_\nu. \) Hence, \( T[\eta/p] \) is an \( A_{\leq m} \)-condition tree and \( T[\eta/p] \leq T. \)

**Lemma 3.16.** Suppose \( \epsilon < \omega_1 \) and \( T \) is an \( A_{\leq m} \)-condition tree. Then there is an \( A_{\leq m} \)-condition tree \( R \leq T \) of height \( \geq \epsilon. \)

**Proof.** Suppose \( \{ \eta_i \mid i < k \}, \) \( k < \omega, \) is an enumeration of \( \text{Ind}(A_{\leq m}). \) We define, by induction on \( j \leq k, \) \( A_{\leq m} \)-condition trees \( R^j \) as follows. Let \( R^0 \) be \( T. \) Suppose \( j < k, \) \( R^i \) for all \( i \leq j \) are defined, and the conditions \( R^j(\eta_i), i < j, \) are of height...
\( \geq \epsilon \). By Lemma 3.2(b) there is \( p \leq R^i(\eta) \) in \( P^* \) having height greater than \( \epsilon \). We define \( R^{i+1} \) to be \( R^i[\eta_i/p] \). It follows that \( R^k \leq T \) is an \( A_{\leq m} \)-condition tree of height \( \geq \epsilon \). \( \square \\

**Definition 3.17.** We fix the following notation for each \( m < \omega \):

\[
\begin{align*}
\text{Val}(A_{\leq m}) &= \{ \tau \mid \tau \text{ is a function from Ind}(A_{\leq m}) \text{ into } F \}, \\
\text{Ind}(A_{\leq m}) &= \{ \eta|\alpha + 1 \mid \alpha \in A_m \text{ and } \eta \in \text{Ind}(A_{\leq m}) \}, \\
\text{IVal}(A_{\leq m}) &= \{ \sigma \mid \sigma \text{ is a function from } \text{Ind}(A_{\leq m}) \text{ into } F \}.
\end{align*}
\]

Let \( m < \omega \), and let \( T \) be an \( A_{\leq m} \)-condition tree. For all \( y \in \text{Vec} \) and \( (\sigma, \tau) \in \text{IVal}(A_{\leq m}) \times \text{Val}(A_{\leq m}) \) we write

\[
T[y] \succeq (\sigma, \tau)
\]

if for each \( \eta \in \text{Ind}(A_{\leq m}) \), both of the requirements

for each \( \alpha \in A_m \), either \( \alpha \) is \( T_\eta \)-trivial or \( T_\eta(\alpha) = \sigma(\eta|\alpha + 1) \)

and

\[
T_\eta \Vdash_{\alpha^*} \tilde{h}(y) = \tau(\eta)
\]

are satisfied. We define \( \text{TPos}(A_{\leq m}) \) to be the set of all \( (\sigma, \tau) \in \text{IVal}(A_{\leq m}) \times \text{Val}(A_{\leq m}) \) with the following property. For all \( A_{\leq m} \)-condition trees \( T \) there exist an unbounded subset \( Y \) of \( \text{Vec} \) and for each \( y \in Y \) an \( A_{\leq m} \)-condition tree \( T^y \leq T \) satisfying \( T^y[y] \succeq (\sigma, \tau) \).

Suppose \( m < \omega \) and \( T \) is an \( A_{\leq m} \)-condition tree. We set

\[
\begin{align*}
\text{Dec}(T) &= \{ y \in \text{Vec} \mid \text{for all } \eta \in \text{Ind}(A_{\leq m}) \text{ and } \alpha \in A_m, \\
&\quad \quad \alpha \text{ is } T_\eta \text{-trivial or supp}(y) \in \text{dom}(T_\eta(\alpha)) \}, \\
\text{Dec}(T) &= \{ y \in \text{Vec} \mid \text{for all } \eta \in \text{Ind}(A_{\leq m}) \text{ and } \alpha \in A_m, \\
&\quad \quad \text{supp}(y) \notin \text{dom}(T_\eta(\alpha)) \}, \\
\text{Dec}_{\tilde{h}}(T) &= \{ y \in \text{Vec} \mid \text{for each } \eta \in \text{Ind}(A_{\leq m}), \\
&\quad \quad T_\eta \text{ decides the value of } \tilde{h}(y) \}.
\end{align*}
\]

For \( i = 0, 1 \), \( (\sigma_i, \tau_i) \in \text{IVal}(A_{\leq m}) \times \text{Val}(A_{\leq m}) \) and \( e_i \in F \) we define the sum

\[
e_0 \cdot (\sigma_0, \tau_0) + e_1 \cdot (\sigma_1, \tau_1)
\]

to be the pair \( (\sigma, \tau) \in \text{IVal}(A_{\leq m}) \times \text{Val}(A_{\leq m}) \), where for all \( v \in \text{Ind}(A_{\leq m}) \) and \( \eta \in \text{Ind}(A_{\leq m}) \)

\[
\begin{align*}
\sigma(v) &= e_0 \cdot \sigma_0(v) + e_1 \cdot \sigma_1(v), \\
\tau(\eta) &= e_0 \cdot \tau_0(\eta) + e_1 \cdot \tau_1(\eta).
\end{align*}
\]

**Lemma 3.18.** Suppose \( m < \omega \) and \( T \) is an \( A_{\leq m} \)-condition tree.

a) For every \( y \in \text{Vec} \) there is an \( A_{\leq m} \)-condition tree \( R \leq T \) for which \( y \in \text{Dec}(R) \cap \text{Dec}_{\tilde{h}}(R) \).

b) For all \( y \in \text{Dec}(T) \) and \( \sigma \in \text{IVal}(A_{\leq m}) \) there are an \( A_{\leq m} \)-condition tree \( R \leq T \) and \( \tau \in \text{Val}(A_{\leq m}) \) such that \( R[y] \succeq (\sigma, \tau) \).

c) For any \( \sigma \in \text{IVal}(A_{\leq m}) \) there is \( \tau \in \text{Val}(A_{\leq m}) \) such that \( (\sigma, \tau) \in \text{TPos}(A_{\leq m}) \).

d) If \( (\sigma_i, \tau_i) \in \text{TPos}(A_{\leq m}) \) and \( e_i \in F \), for \( i = 0, 1 \), then \( \sum_{i=0}^1 e_i \cdot (\sigma_i, \tau_i) \) is in \( \text{TPos}(A_{\leq m}) \).
Proof. a) Suppose $\text{Ind}(A_{< m}) = \{ \eta_i \mid i < k \}$. Let $R^0$ be $T$. Assume $A_{< m}$-condition trees $R^i$, $i \leq j < k$, are already defined.

(A) By Lemma 2.3(a) there is $p \leq R^j(\eta_j)$ in $P^*$ for which $\text{supp}(y) \in \text{dom}(p(\alpha))$ for all $\alpha \in A_m$.

Assume $q < p$ in $P^*$ decides the value of $\tilde{h}(y)$, and define $R^{j+1}$ to be $R^j[\eta_j/q]$. Then $y \in \text{Dec}(R^k) \cap \text{Dec}_h(R^k)$.

b) This is proved as (a). The only difference is that instead of (A) the following is used:

by Lemma 3.5(b) there is $p \leq R^j(\eta_j)$ in $P^*$ such that, for each $\alpha \in A_m$,

either $\alpha$ is $p$-trivial or $p(\alpha)(y) = \sigma(\eta_j[\alpha + 1])$.

Then the function $\tau \in \text{Val}(A_{< m})$ satisfying $R^k[\eta] \succeq (\sigma, \tau)$ is uniquely determined by $R^k$.

c) Since $T$ and the domains of the conditions in $T$ are countable, there must be a limit $\theta_T < \omega_1$ such that, for every $y \in \text{Vec}$, $\min(\text{supp}(y)) > \theta_T$ implies $y \notin \text{Dec}(T)$. Hence, directly by (b), for every $y \in \text{Dec}(T)$ there are $T^y \leq T$ and $\tau^y \in \text{Val}(A_{< m})$ satisfying $T^y[\eta] \succeq (\sigma, \tau^y)$. Since $\text{Val}(A_{< m})$ is countable and $\text{Dec}(T)$ uncountable, there must be an unbounded subset $Y$ of $\text{Dec}(T)$ and $\tau \in \text{Val}(A_{< m})$ such that $\tau = \tau^y$ for each $y \in Y$. Thus $Y$ and the trees $\langle T^y \mid y \in Y \rangle$ stronger than the arbitrary $A_{< m}$-condition tree $T$ exemplify $(\sigma, \tau)$ in $\text{TPos}(A_{< m})$.

d) Since $(\sigma_0, \tau_0) \in \text{TPos}(A_{< m})$, there are an unbounded subset $Y$ of $\text{Vec}$ and, for each $y \in Y$, an $A_{< m}$-condition tree $T^y_0 \leq T$ satisfying $T^y_0[\eta] \succeq (\sigma_0, \tau_0)$. Because $(\sigma_1, \tau_1) \in \text{TPos}(A_{< m})$, there exist for each $y \in Y$ an $A_{< m}$-condition tree $T^y_1 \leq T^y_0$ and an element $z_y \in \text{Vec}$ such that $\max(\text{supp}(y)) < \min(\text{supp}(z_y))$ and $T^y_1[z_y] \succeq (\sigma_1, \tau_1)$. Consequently, for all $y \in Y$,

$$T^y_1[e_0 y + e_1 z_y] \succeq e_0 \cdot (\sigma_0, \tau_0) + e_1 \cdot (\sigma_1, \tau_1).$$

So the unbounded subset $\{ (e_0 y + e_1 z_y) \mid y \in Y \}$ of $\text{Vec}$ and the trees $\langle T^y_1 \mid y \in Y \rangle$ stronger than an arbitrary $T$ exemplify that $\sum_{i=0,1} e_i \cdot (\sigma_i, \tau_i)$ is in $\text{TPos}(A_{< m})$. \hfill \Box

We let $0^\text{Val}_{\text{m}}$ be the 0-function of $\text{IVal}(A_{< m})$ and $0^\text{Val}_{\text{m}}$ the 0-function of $\text{Val}(A_{< m})$. For all $\tau \in \text{Val}(A_{< m})$, $\eta \in \text{Ind}(A_{< m})$, and $d \in F$, $\tau[\eta \mapsto d]$ denotes the function in $\text{Val}(A_{< m})$ which is the same as $\tau$ except it maps $\eta$ into $d$.

**Lemma 3.19.** For every $\sigma' \in \text{IVal}(A_{< m})$ the pair $(\sigma', 0^\text{Val}_{\text{m}})$ is in $\text{TPos}(A_{< m})$.

**Proof.** We shall prove the following claim.

For every $\eta_0 \in \text{Ind}(A_{< m})$ there are $(\sigma, \tau) \in \text{TPos}(A_{< m})$ and $d_1 \in F$ such that $d_1 \neq \tau(\eta_0)$ and $(\sigma, \tau[\eta_0 \mapsto d_1])$ is in $\text{TPos}(A_{< m})$.

This suffices, because if the claim holds then by Lemma 3.18(d)

$$
\frac{1}{\tau(\eta_0) - d_1} \cdot ((\sigma, \tau) - (\sigma, \tau[\eta_0 \mapsto d_1]))
= \frac{1}{\tau(\eta_0) - d_1} \cdot (0^\text{Val}_{\text{m}}[\eta_0 \mapsto \tau(\eta_0) - d_1])
= (0^\text{Val}_{\text{m}}, 0^\text{Val}_{\text{m}}[\eta_0 \mapsto 1]) \in \text{TPos}(A_{< m}),
$$
for all \(\eta_0 \in \text{Ind}(A_{\leq m})\). Furthermore, by Lemma 3.18(c), there is \(\tau' \in \text{Val}(A_{\leq m})\) for which \((\sigma', \tau') \in \text{TPos}(A_{\leq m})\), and hence, by Lemma 3.18(d),

\[
(\sigma', \tau') - \sum_{\eta_0 \in \text{Ind}(A_{\leq m})} \tau'(\eta_0) \cdot (0^{\text{Val}}_m, 0^{\text{Val}}_m[\eta_0 \mapsto 1]) = (\sigma', \tau') - (0^{\text{Val}}_m, \tau') = (\sigma', 0^{\text{Val}}_m) \in \text{TPos}(A_{\leq m}).
\]

For the rest of the proof of the lemma let \(\alpha\) be the maximal element of \(A_m\), \(T\) an \(A_{\leq m}\)-condition tree, and \(\eta_0\) an arbitrary element of \(\text{Ind}(A_{\leq m})\). By Lemma 3.15(c) there are \(c, d_0 \neq d_1 \in F\), an unbounded subset \(Z\) of Vec, and conditions \(p^y_0, p^y_1 \leq T(\eta_0)\), for each \(y \in Z\), exemplifying \((c, d_0, c, d_1) \in \text{Pos}_a(T(\eta_0))\). This means that for all \(y \in Z\), \(i = 0, 1\), and \(\beta \in A_m\),

\[
\begin{align*}
p^y_0|\alpha &= p^y_1|\alpha, \\
p^y_0 \upharpoonright \alpha &\Rightarrow \tilde{h}(y) = d_i, \\
p^y_0(\beta)(y) &= p^y_1(\beta)(y) \text{ or } \beta \text{ is } p^y_0\text{-trivial for both } i = 0 \text{ and } 1.
\end{align*}
\]

By Lemma 3.18(a) there is an \(A_{\leq m}\)-condition tree \(T^y \leq T[\eta_0/p^y_0]\) for every \(y \in Z\) such that \(y \in \text{Dec}(T^y) \cap \text{Dec}_h(T^y)\). Since \(Z\) is uncountable, there must be an unbounded subset \(Y\) of \(Z\) and \((\sigma, \tau) \in \text{Val}(A_{\leq m}) \times \text{Val}(A_{\leq m})\) such that \(T^y[y] \simeq (\sigma, \tau)\) for all \(y \in Y\). So \(Y\) and the trees \((T^y \upharpoonright y \in Y)\) stronger than an arbitrary tree \(T\) exemplify \((\sigma, \tau)\) in \(\text{TPos}(A_{\leq m})\). Observe that \(T^y(\eta_0) \leq p^y_0\) implies \(T^y(\eta_0) \upharpoonright \alpha \Rightarrow \tilde{h}(y) = \tau(\eta_0) = d_0\).

Now, the function

\[
R^y = T^y[\eta_0/\text{TPos}(A_{\leq m})[\alpha] \upharpoonright p^y]
\]

is a \(A_{\leq m}\)-condition tree for each \(y \in Y\), since \(T^y(\eta_0)[\alpha] \leq p^y_0[\alpha] = p^y_0|\alpha\). Hence \(Y\) and \((R^y \upharpoonright y \in Y)\) exemplify \((\sigma, \tau)[\eta_0 \mapsto d_1] \in \text{TPos}(A_{\leq m})\). \(\quad \Box\)

We are now ready to give the last missing piece.

**Proof of Lemma 3.12.** Fix a countable elementary submodel \(\mathcal{M}\) of \(H_{\alpha^*}(p^*, \tilde{h})\) satisfying \(\mathcal{M} \cap \omega_1 = \delta^* \in S\). We define \(A^* = \mathcal{M} \cap \alpha^*\). Let \(\tilde{A}\) be a filter of \(A^*\). Since the sets \(A_m \in A^* \subseteq \mathcal{M}\), \(m < \omega\), are finite, they belong to \(\mathcal{M}\) as well as the sets \(\text{Ind}(A_{\leq m})\), \(\text{Ind}(A_{\leq m})\), and \(\text{Val}(A_{\leq m})\). Let \(\tilde{c} = \langle \zeta_m \mid m < \omega \rangle\) be an increasing sequence of ordinals with limit \(\delta^*\).

For each \(m < \omega\) we define the \(A_m\)-complete element of \(\text{Val}(A_{\leq m})\) to be the unique \(\sigma \in \text{Val}(A_{\leq m})\) for which \(\sigma(\eta[\alpha + 1] = \eta(\alpha, m)\) for all \(\eta \in \text{Ind}(A_{\leq m})\) and \(\alpha \in A_m\).

We define a ladder \(\tilde{y} = \langle y_m \mid m < \omega \rangle\) on \(\delta^*\) and an \((\tilde{c}, \tilde{y})\)-tree system \((T^m \mid m < \omega)\) on \(\tilde{A}\) by induction on \(m < \omega\). Our main tool is Lemma 3.19, which will ensure that \(T^m_\eta\) forces \((\tilde{h}(y_m) = 0)\) for all \(m < \omega\) and \(\eta \in \text{Ind}(A_{\leq m})\). During the induction we work inside \(\mathcal{M}\).

Suppose \(m = 0\). We define a trivial \(A_{\leq 0}\)-condition tree \(R\) in \(\mathcal{M}\) by \(R(\eta) = p^*\) for each \(\eta \in \text{Ind}(A_{\leq 0})\). Note that \(\text{dom}(p^*) \in \{0\} \cup A^*\). By Lemma 3.16 there is in \(\mathcal{M}\) an \(A_{\leq 0}\)-condition tree \(R^0 \leq R\) which is of height \(\geq \varepsilon_0\). By Lemma 3.19 there are \(y_0 \in \text{Vec} \cap \mathcal{M}\) and an \(A_{\leq 0}\)-condition tree \(T^0 \leq R^0\) in \(\mathcal{M}\) satisfying

\[
\varepsilon_0 < \min(\text{supp}(y_0)) \text{ and } T^0[y_0] \simeq (\sigma, 0^{\text{Val}}_m),
\]

where \(\sigma\) is the \(A_0\)-complete element of \(\text{Val}(A_{\leq 0})\).
Similarly, when \( y_m \in \text{Vec} \cap \mathcal{M} \) and \( T^m \) in \( \mathcal{M} \) are already defined, we can find \( y_{m+1} \in \text{Vec} \cap \mathcal{M} \) and an \( A_{\leq m+1} \)-condition tree \( T^{m+1} \leq T^m \) in \( \mathcal{M} \) satisfying
\[
\begin{align*}
\max \{ \epsilon_{m+1}, \max(\text{supp}(y_m)) \} &< \min(\text{supp}(y_{m+1})), \\
T^{m+1} &\text{ is of height } \geq \epsilon_{m+1}, \\
T^{m+1}[y_{m+1}] &\models (\sigma, 0^{\text{Val}}_{m+1}),
\end{align*}
\]
where \( \sigma \in \text{IVal}(A_{\leq m+1}) \) is \( A_{m+1} \)-complete.

It follows directly from the definition above that \( \bar{y} \) is a ladder on \( \delta^* \) and, for every \( m < \omega \),
\[
\begin{align*}
T^m &\text{ is an } A_{\leq m} \text{-condition tree,} \\
\text{for all } \eta \in \text{Ind}(A_{\leq m}), \text{ dom}(T^m_\eta) &\subseteq \{0\} \cup A^*, \\
T^m &\text{ is of height } \geq \epsilon_m \text{ and } < \delta^*, \\
T^{m+1} &\leq T^m.
\end{align*}
\]
Moreover, for each \( m < \omega \) and \( \eta \in \text{Ind}(A_{\leq m}) \) the property \( T^m[y_m] \models (\sigma, 0^{\text{Val}}_m) \) guarantees that
\[
\begin{align*}
T^m_\eta &\models \alpha^* \hat{h}(y_m) = 0^{\text{Val}}_m(\eta) = 0,
\end{align*}
\]
and, since \( \sigma \) is \( A_m \)-complete,
\[
\alpha \text{ is } T^m_\eta \text{-trivial or } T^m_\eta(\alpha)(y_m) = \sigma(\eta|\alpha + 1) = \eta(\alpha, m), \text{ for all } \alpha \in A_m.
\]

\[ \square \]

### 3.3. Remarks.

There is a forcing notion which gives the conclusion of Theorem 2 for all finite fields simultaneously. Namely, we defined an iterated forcing \( P_k = \text{CountLim} \langle P_\alpha, \bar{Q}_\alpha^k \mid \alpha < \omega_2 \rangle \) for fixed \( k \). The extended result would follow if each \( \bar{Q}_{\alpha}^k \) was replaced by \( \bar{Q}_{\alpha}^2 \times \bar{Q}_{\alpha}^3 \times \ldots \), where \( \bar{Q}_{\alpha}^i \) takes care of the case \( \pi(i) = (p, m) \) and \( \pi \) is a coding for the pairs of primes and positive integers. So \( F_i \) would be the field of size \( p^m \), where \( \pi(i) = (p, m) \). For example, to prove that for each “coordinate” \( i \) the cardinality of \( \text{Col}_{S,F}/\text{Unif}_{x,D} \) is as wanted, it would suffice to concentrate on one coordinate \( i \), and define the condition trees and systems, \( \text{Pos}_s(p) \), etc., only for fixed \( i \). Hence an assumption that the size is wrong for some \( i \) would lead to a contradiction in the same way as in Subsection 3.2.

It is possible to have a \( \text{Vec}_F \)-ladder system on \( S \) such that \( \text{card}(\text{Col}_{S,F}/\text{Unif}_{x,D}) = \aleph_0 \). A proof of this fact would be a forcing argument just like the one we have given. The only difference is that instead of one generic colouring \( \bar{b} \), one should add generic colourings \( \langle \bar{b}_m \mid m < \omega \rangle \) by defining \( Q_0 = \text{Ilad} \times \text{ICol} \). Then by replacing \( \langle \bar{b}_i \rangle_{F} + \text{Unif} \) with \( \langle \langle \bar{b}_0, \bar{b}_1, \ldots \rangle_F + \text{Unif} \rangle \) the desired result would follow. The conclusion of such a generalized theorem would be
\[
\begin{align*}
\models_F \text{card}(\text{Col}_{S,F}/\text{Unif}_{x,D}) = \text{card}(\langle \bar{b}_0, \bar{b}_1, \ldots \rangle_F) = \aleph_0.
\end{align*}
\]
Other changes would be, for example, that Lemma 3.6 would have the form \( \models_1 \) “if \( \chi \in \langle \bar{b}_0, \bar{b}_1, \ldots \rangle_F \) then \( \chi \notin \text{Unif} \)”, and analogous changes would be needed in Lemma 3.15.

We may also continue the iteration longer than \( \omega_2 \) and get the consistency of our main result with \( \text{CH+} \) “any reasonable value for \( 2^{\aleph_1} \)”. The \( \aleph_2 \)-c.c. for such a forcing follows from the use of \( \aleph_2 \)-P.I.C. \cite{She82b} or, better, \cite{She98} Section 2 of Chapter 8.

During the given proof, for example in Lemma 3.3, it is possible to use the general claim on preservation of \( (\omega_1 \setminus S) \)-complete forcing notions and the preservation
of properness for the preservation of stationarity [She82b Chapter 5] or [She98 Chapter 5]. But this does not, however, help with the main problem.

4. The Models

As in the preceding sections, we assume that $S \subseteq \omega_1$ is a set of limit ordinals, $F$ is a field, $D$ is a filter over $\omega$, $\mathcal{F}$ is the vector space over $F$ freely generated by $\{x_\xi \mid \xi < \omega_1\}$, $x$ is a Vec-ladder system on $S$, Col denotes the set of all $F$-colourings on $S$, and Unif is the set of all uniform colourings.

Let $\mathcal{M}$ be a model of vocabulary $\rho$, $0 < n < \omega$, and $R \in \rho$ a relation symbol with $n + 1$ places. We say that $R$ is a partial function in $\mathcal{M}$ if there are $X \subseteq \mathcal{M}^n$ and $Y \subseteq Y$ such that the interpretation $R^\mathcal{M}$ of the symbol $R$ in $\mathcal{M}$ is a function from $X$ into $Y$. For all relations $R \in \rho$ which are partial functions in $\mathcal{M}$, $R^\mathcal{M}(x) = y$ means $x \sim (y) \in R^\mathcal{M}$, and atomic formulas $R(x, y)$ are written in the form $R(x) = y$.

Definition 4.1. We define a vocabulary $\rho$ and for all $a \in \Col$ models $\mathcal{M}_a$ of vocabulary $\rho$ by the following stipulations:

a) Each model $\mathcal{M}_a$ has the same domain $(S \times F^<\omega) \cup (\text{Vec} \times F)$, where

$$F^<\omega = \{ u \in \omega F \mid \{ n \in \omega \mid u(n) = 0 \} \in D \}.$$ 

b) For each $y \in \text{Vec}$, $R_y$ is a unary relation symbol in $\rho$ and $R_y^\mathcal{M}_a = \{ y \} \times F$.

c) For each $\delta \in S$, $R_\delta$ is a unary relation symbol in $\rho$ and $R_\delta^\mathcal{M}_a = \{ \delta \} \times F^<\omega$.

d) For each $n < \omega$, $Pr_n^a$ denotes a function from $S \times F^<\omega$ into $\text{Vec} \times F$ defined for all $(\delta, u) \in S \times F^<\omega$ by

$$Pr_n^a(\delta, u) = (x_{\delta, u}, a_{\delta, u} + F u(n)).$$

For each $n < \omega$, $Pr_n$ is a binary relation in $\rho$ and $Pr_n^\mathcal{M}_a = Pr_n^a$. So $Pr_n$ is a partial function in $\mathcal{M}_a$.

e) For all $b \in F$, $+b \in \rho$, $+b^\mathcal{M}_a : \text{Vec} \times F \to \text{Vec} \times F$, and for all $(y, c) \in \text{Vec} \times F$,

$$+b^\mathcal{M}_a(y, c) = (y, c + F b).$$

f) For all $u \in F^<\omega$, $+u \in \rho$, $+u^\mathcal{M}_a : S \times F^<\omega \to S \times F^<\omega$, and for all $(\delta, v) \in S \times F^<\omega$,

$$+u^\mathcal{M}_a(\delta, v) = (\delta, v + (F^<\omega) u),$$

where $v + (F^<\omega) u$ is the function in $F^<\omega$ defined for all $n < \omega$ by

$$v + (F^<\omega) u(n) = v(n) + F u(n).$$

g) The symbol $+$ is in $\rho$, $+^\mathcal{M}_a : (\text{Vec} \times F)^2 \to \text{Vec} \times F$, and for all $(y, b), (z, c) \in \text{Vec} \times F$,

$$(y, b) +^\mathcal{M}_a (z, c) = (y + _\text{vec} z, b + F c).$$

h) For each $e \in F$, $e \cdot$ is a binary relation in $\rho$, $e^\mathcal{M}_a : \text{Vec} \times F \to \text{Vec} \times F$, and for all $(y, b) \in \text{Vec} \times F$,

$$e^\mathcal{M}_a(y, b) = (e \cdot _\text{vec} y, e \cdot F b).$$

Remark. The cardinality of $\rho$ is $\aleph_1$ just for convenience. A finite vocabulary is possible by parameterizing the relations as in [She85 Claim 1.4].

For each $s \in \rho \setminus \{ Pr_n \mid n < \omega \}$, the interpretation $s^\mathcal{M}_a$ is the same for all $a \in \Col$. Hence we omit the superscript $\mathcal{M}_a$. 
For \( \mu < \omega_1 \), the restriction of \( \mathcal{M}_a \) to the set 
\[
\{ \{ y \in \text{Vec} \mid \text{supp}(y) \subseteq \mu \} \times F \} \cup ((S \cap \mu + 1) \times F^{< \omega})
\]
is denoted by \( \mathcal{M}_a|\mu + 1 \).

**Lemma 4.2.** Suppose \( a, b \in \text{Col} \) and \( \mu \leq \omega_1 \).

a) If \( f : \mu \to F \) uniformizes \( (b - a)|\mu + 1 \), then \( \mathcal{M}_a|\mu + 1 \cong \mathcal{M}_b|\mu + 1 \).

b) If \( \mathcal{M}_a|\mu + 1 \cong \mathcal{M}_b|\mu + 1 \), then there is \( f : \mu \to F \) which uniformizes \( (b - a)|\mu + 1 \).

c) \( \mathcal{M}_a \cong_{\omega_1} \mathcal{M}_b \).

**Proof.** a) Suppose \( f : \mu \to F \) uniformizes \( (b - a)|\mu + 1 \). We define \( \iota : \mathcal{M}_a|\mu + 1 \cong \mathcal{M}_b|\mu + 1 \) by the following equations:

For all \( \xi < \mu \),
\[
\iota(x_\xi, 0) = (x_\xi, f(\xi)),
\]
and for all \( (y, c) \in \text{Vec} \times F \), we set
\[
\iota(y, c) = +c(\sum_{\xi < \mu} d_{\xi} \cdot (\iota(x_\xi, 0)))
= (\sum_{\xi < \mu} d_{\xi} x_\xi, (\sum_{\xi < \mu} d_{\xi} \cdot f(\xi)) + c)
= (y, f(y) + c),
\]
where \( y \) is of the form \( \sum_{\xi < \mu} d_{\xi} x_\xi \), \( d_{\xi} \in F \), and \( f(y) = \sum_{\xi < \mu} d_{\xi} \cdot f(\xi) \) as in Section 2.

For all \( \delta \in S \cap \mu + 1 \),
\[
\iota(\delta, 0) = (\delta, \hat{0}_\delta^f),
\]
where \( \hat{0} \) denotes the 0-function of \( F^{< \omega} \), and \( \hat{0}_\delta^f \) is a function from \( \omega \) into \( F \) defined for all \( n < \omega \) by
\[
\hat{0}_\delta^f(n) = (\sum_{\xi < \delta} e_{\xi}^\delta \cdot f(\xi)) - (b_{\delta,n} - a_{\delta,n})
= f(x_{\delta,n}) - (b_{\delta,n} - a_{\delta,n}),
\]
where \( x_{\delta,n} \) is of the form \( \sum_{\xi < \delta} e_{\xi}^\delta x_\xi \), and, for all \( \xi < \delta, e_{\xi}^\delta \in F \).

Furthermore, for all \( (\delta, u) \in (S \cap \mu + 1) \times F^{< \omega} \) we define
\[
\iota(\delta, u) = +u(\iota(\delta, 0)) = (\delta, \hat{0}_\delta + u).
\]

Since \( f \) uniformizes \( (b - a)|\mu + 1 \), the function \( \hat{0}_\delta^f \) is in \( F^{< \omega} \) for all \( \delta \in S \cap \mu + 1 \). Clearly \( \iota \) is bijective, and by its definition it preserves all the interpretations of the symbols in \( \rho \setminus \{ \Pr_n \mid n < \omega \} \). Hence, to prove that \( \iota \) is an isomorphism, it suffices
to show that, for all \( n < \omega \) and \( (\delta, u) \in (S \cap \mu + 1) \times F^{<\omega} \),
\[
\iota(P_n^{a_1}(\delta, u)) = \iota(x_{\delta, n}, a_{\delta, n} + u(n))
\]
\[
= (x_{\delta, n}, f(x_{\delta, n}) + a_{\delta, n} + u(n))
\]
\[
= (x_{\delta, n}, b_{\delta, n} + f(x_{\delta, n}) - (b_{\delta, n} - a_{\delta, n}) + u(n))
\]
\[
= (x_{\delta, n}, b_{\delta, n} + \hat{0}_{f}^\iota(n) + u(n))
\]
\[
= \Pr_n^{b_1}(\delta, \hat{0}_{f}^\iota + u)
\]
\[
= \Pr_n^{b}(\iota(\delta, u)).
\]

b) Suppose then \( \iota : M_s | \mu + 1 \cong M_b | \mu + 1 \). We let \( f : \mu \rightarrow F \) be the unique function satisfying, for all \( \xi < \mu \) and \( c \in F \), \( f(\xi) = c \) iff \( \iota(x_\xi, 0) = (x_\xi, c) \).

Assuming that \( x_{\delta, n} \) is of the form \( \sum_{\xi < \delta} c_{\xi} x_\xi \), for all \( \delta \in S \) and \( n < \omega \) the following equation holds in both models:
\[
(x_{\delta, n}, 0) = (\sum_{\xi < \delta} c_{\xi} x_\xi, 0) = \sum_{\xi < \delta} c_{\xi} x_\xi (0).
\]

Hence the isomorphism \( \iota \) satisfies
\[
\iota(x_{\delta, n}, 0) = \sum_{\xi < \delta} c_{\xi} x_\xi (\iota(0, 0))
\]
\[
= \sum_{\xi < \delta} c_{\xi} x_\xi (0)
\]
\[
= \iota(x_{\delta, n}, f(x_{\delta, n})).
\]

In addition to this, \( \iota(x_{\delta, n}, a_{\delta, n}) = (x_{\delta, n}, f(x_{\delta, n}) + a_{\delta, n}) \). So the following equation holds for all \( \delta \in S \cap \mu + 1 \) and \( n < \omega \):
\[
(x_{\delta, n}, f(x_{\delta, n}) + a_{\delta, n}) = \iota(x_{\delta, n}, a_{\delta, n}) = \iota(P_n^{a_1}(\delta, \hat{0}))
\]
\[
= \Pr_n^{b}(\iota(\delta, \hat{0}))
\]
\[
= \Pr_n^{b}(\delta, \hat{0}_{f}^\iota(n))
\]
\[
= (x_{\delta, n}, b_{\delta, n} + \hat{0}_{f}^\iota(n)).
\]

where \( \hat{0}_{f}^\iota \) is the function in \( F^{<\omega} \) satisfying \( \iota(\delta, \hat{0}) = (\hat{0}_{f}, \hat{0}_{f}) \). It follows that, for all \( \delta \in S \cap \mu + 1 \) and \( n < \omega \),
\[
b_{\delta, n} - a_{\delta, n} = f(x_{\delta, n}) - \hat{0}_{f}^\iota(n).
\]

Since \( \hat{0}_{f}^\iota \in F^{<\omega} \), \( (b - a)(\delta) \approx f(x(\delta)) \) for all \( \delta \in S \cap \mu + 1 \), i.e., \( f \) uniformizes \( (b - a)|\mu + 1 \).

c) To prove the claim we show that for all \( \mu_0 < \mu_1 < \omega_1 \) and \( \iota_0 : M_{a_1} | \mu_0 + 1 \cong M_{b_1} | \mu_0 + 1 \), there is \( \iota_1 : M_{a_1} | \mu_1 + 1 \cong M_{b_1} | \mu_1 + 1 \) which is an extension of \( \iota_0 \). This suffices by [Diac85] Theorem 4.3.1 on page 353.

By (b) the existence of \( \iota_0 \) implies that there is \( f_0 : \mu_0 \rightarrow F \) uniformizing \( (b - a)|\mu_0 + 1 \). By Lemma 2.3 there is an extension \( f_1 : \mu_1 \rightarrow F \) of \( f_0 \) which uniformizes \( (b - a)|\mu_1 + 1 \). Hence by (a), there is \( \iota_1 : M_{a_1} | \mu_1 + 1 \cong M_{b_1} | \mu_1 + 1 \).

It can be easily seen from the proof of (b) that if \( \mu \leq \omega_1 \), \( \iota' : M_{b_1} | \mu + 1 \cong M_{b_1} | \mu + 1 \), and \( f : \mu \rightarrow F \) is the function given in the proof of (b), then the isomorphism \( \iota \) given in the proof of (a) is the same as \( \iota' \). Hence \( f_0 \cong f_1 \) implies \( \iota_0 \cong \iota_1 \).
Lemma 4.3.

a) For all \( a, b \in \text{Col} \), \( M_a \cong M_b \) iff \( a \sim b \).
b) Suppose \( N \) is a model of vocabulary \( \rho \), \( \text{card}(N) = \aleph_1 \), and \( N \equiv_{\text{b}_{\omega_1}} M_a \) for some \( a \in \text{Col} \). Then there is \( b \in \text{Col} \) such that \( N \cong M_b \).

c) For each \( a \in \text{Col} \), \( \text{No}(M_a) = \text{card}(\text{Col}/\text{Unif}) \).

Proof. (a) holds by (a) and (b) of Lemma 4.2.

b) We let \( \phi_\delta \), for all \( \delta \in S \), be the following \( L_{\text{b}_{\omega_1}}(\rho) \)-sentence:

\[
\exists (r_\delta, n \mid n < \omega) \forall s \in R_\delta \left( \bigwedge_{i \in D} \left( \bigwedge_{n \in I} \Pr_n(s) = r_\delta, n \land \bigwedge_{n \in \omega \setminus I} \Pr_n(s) \neq r_\delta, n \right) \right).
\]

For all \( \delta \in S \), \( \phi_\delta \) holds in \( N \) since the interpretation \( r_\delta, n = (x_\delta, n, a_\delta, n) \), for all \( \delta \in S \) and \( n < \omega \), satisfies the formula in \( M_a \). We let \( \langle r_\delta, n \mid n < \omega \rangle \), \( \delta \in S \), be a sequence of elements in \( N \) satisfying \( \phi_\delta \), and \( s_\delta \) the unique element in \( R_\delta^N \) which satisfies \( \Pr_n^N(s_\delta) = r_\delta, n \) for all \( n < \omega \).

We define \( \iota : (S \times F^{<\omega}) \cup (\text{Vec} \times F) \rightarrow N \) by the following stipulations.

For all \( \delta \in S \),

\[
\iota(\delta, 0) = s_\delta,
\]

(where \( 0 \) denotes the 0-function of \( F^{<\omega} \)), and for all \( (\delta, u) \in S \times F^{<\omega} \),

\[
\iota(\delta, u) = +u^N(\iota(\delta, 0)).
\]

For all \( \xi < \omega_1 \), \( \iota(x_\xi, 0) \) is an arbitrary element in \( R_{x_\xi}^N \), and for all \( y \in \text{Vec} \),

\[
\iota(y, 0) = \sum_{\xi < \omega_1} \left( (d_\xi) \iota(x_\xi, 0) \right),
\]

where \( y \) is of the form \( \sum_{\xi < \mu} d_\xi x_\xi \). For all \((y, c) \in \text{Vec} \times F \), set \( \iota(y, c) = +c^N(\iota(y, 0)) \).

Using \( \iota \), we define \( b \) to be the \( F \)-colouring on \( S \) which satisfies, for all \( \delta \in S \) and \( n < \omega \),

\[
\iota(x_\delta, n, b_\delta, n) = r_\delta, n.
\]

Such a colouring exists since \( \iota \) is surjective.

To show that \( \iota \) is an isomorphism between \( M_b \) and \( N \), we first note that \( \iota \) is a bijection, and that the preservations of the interpretations of the symbols in \( \rho \setminus \{ \Pr_n \mid n < \omega \} \) are obvious. So it suffices to check that

\[
\iota(\Pr_n^b(\delta, u)) = \Pr_n^N(\iota(\delta, u))
\]

for all \( n < \omega \) and \( (\delta, u) \in S \times F^{<\omega} \). For all \( u \in F^{<\omega} \), \( n < \omega \), and \( s \in R_\delta^N \),

\[
+u(n)^N(\Pr_n^N(s)) = \Pr_n^N(+u^N(s)),
\]

since in \( M_a \), for all \((\delta, v) \in S \times F^{<\omega} \),

\[
+u(n)(\Pr_n^a(\delta, v)) = +u(n)(x_\delta, n, a_\delta, n + v(n)) = (x_\delta, n, a_\delta, n + v(n) + u(n)) = (x_\delta, n, a_\delta, n + (v + u)(n)) = \Pr_n^a(\delta, v + u) = \Pr_n^a(+u(\delta, v)).
\]
Thus for all \( n < \omega \) and \( (\delta, u) \in S \times F^{<\omega} \) the following equation holds:

\[
\iota(P_{\delta}^{\mathcal{M}}(\delta, u)) = \iota(x_{\delta,n}, b_{\delta,n} + u(n)) = +u(n)^{P_{\delta}^{\mathcal{M}}(\delta, n)} = +u(n)^{P_{\delta}^{\mathcal{M}}(r_{\delta,n})} = +u(n)^{P_{\delta}^{\mathcal{M}}(s_{\delta})} = +u(n)^{P_{\delta}^{\mathcal{M}}(s_{\delta})} = +u(n)^{P_{\delta}^{\mathcal{M}}(s_{\delta})} = +u(n)^{P_{\delta}^{\mathcal{M}}(s_{\delta})},
\]

where we assume that \( \iota \) preserves the interpretations of symbols \( +u(n) \) and \( +u \).

c) By Lemma 4.2(c) and (a), \( \text{No}(\mathcal{M}_a) \) is at least \( \text{card}((\mathcal{M}_c/\cong \mid c \in \text{Col}_S F/\text{Unif}_{\mathbf{x}, D}) \). On the other hand, (b) shows that

\[
\text{No}(\mathcal{M}_a) \leq \text{card}((\mathcal{M}_c/\cong \mid c \in \text{Col}_S F/\text{Unif}_{\mathbf{x}, D}) = \text{card}((\mathcal{M}_c/\cong \mid c \in \text{Col}_S F/\text{Unif}_{\mathbf{x}, D})).
\]

\[
\textbf{Proof of Theorem 1.} \text{Let } S \text{ be bistationary in } \omega_1 \text{ and } F \text{ of size } 2. \text{Then by Theorem 2 it is consistent with } \text{ZFC} + \text{GCH} \text{ that there is a Vec-ladder system } \mathbf{x} \text{ on } S \text{ such that } \text{card}((\mathcal{M}_c/\cong \mid c \in \text{Col}_S F/\text{Unif}_{\mathbf{x}, D}). \text{Then, for any } a \in \text{Col}, \text{No}(\mathcal{M}_a) = 2 \text{ by Lemma 4.3(c). Now Theorem 1 follows from the following fact [She82a]:}
\]

\[
\text{if there is a model } \mathcal{M} \text{ for which } \text{No}(\mathcal{M}) = 2, \text{ then for each } k < \omega \text{ there is a model } \mathcal{M}_k \text{ of the same cardinality as } \mathcal{M} \text{ with } \text{No}(\mathcal{M}_k) = k.
\]

We sketch the proof of this fact. Fix \( 1 < l < \omega \) and let \( \lambda = \text{card}(\mathcal{M}) \). Define \( \mathcal{M}_{l+1} \) to be the disjoint union of \( l \) copies of \( \mathcal{M} \). Add a binary relation symbol \( \sim \) to \( \rho \), say \( \rho' = \rho \cup \{ \sim \} \), and for all \( x, y \in \mathcal{M}_{l+1} \) set \( x \sim \mathcal{M}_{l+1} \) \( y \text{ iff } x \text{ and } y \text{ are in the same copy of } \mathcal{M} \). Then each model of cardinality \( \lambda \) which is \( L_{\infty}(\rho') \)-equivalent to \( \mathcal{M}_{l+1} \) must have the same structure as \( \mathcal{M}_{l+1} \), i.e., it is a disjoint union of \( l \) equivalence classes under \( \sim \), and each class alone forms a model \( \mathcal{N}_i \), \( i < l \), of cardinality \( \lambda \) which is \( L_{\infty}(\rho') \)-equivalent to \( \mathcal{M} \). Since there are \( l+1 \) ways to select, up to isomorphism, the models \( \mathcal{N}_i \equiv_{\infty} \mathcal{M} \) for \( i < l \) (the order in the selections of the \( \mathcal{N}_i \) is immaterial—only the number of \( \mathcal{N}_i \) which are isomorphic to \( \mathcal{M} \) matters), and because all such selections are pairwise \( L_{\infty}(\rho') \)-equivalent, \( \text{No}(\mathcal{M}_{l+1}) \) must be \( l+1 \).
