ON NONLINEAR OSCILLATIONS
IN A SUSPENSION BRIDGE SYSTEM

ZHONGHAI DING

Abstract. In this paper, we study nonlinear oscillations in a suspension bridge system governed by two coupled nonlinear partial differential equations. By applying the Leray-Schauder degree theory, it is proved that the suspension bridge system has at least two solutions, one is a near-equilibrium oscillation, and the other is a large amplitude oscillation.

1. Introduction

The suspension bridge is a common type of civil engineering structure. It is well known that suspension bridges may display certain oscillations under external aerodynamic forces. Under the action of a strong wind, for example, a narrow and very flexible suspension bridge can undergo dangerous oscillations [1]. Based upon the observation of the fundamental nonlinearity in suspension bridges that the stays connecting the supporting cables and the roadbed resist expansion, but do not resist compression, new models describing oscillations in suspension bridges have been developed recently by Lazer and McKenna in [10]. The new models are described by systems of coupled nonlinear partial differential equations. The new study of suspension bridges initiated by Lazer and McKenna has produced many important and interesting results. Multiple large amplitude periodic oscillations have been found theoretically and numerically in the single Lazer-McKenna suspension bridge equation (see [3], [8], [10], [12] and references therein). However, there has been very little discussion on nonlinear periodic oscillations in suspension bridge systems of coupled nonlinear partial differential equations in the existing literature. In [2], Ahmed and Harbi investigated the asymptotic stability of a suspension bridge system governed by the coupled nonlinear beam and wave equations with nonlinear damping terms. The same system with linear damping terms has been studied also in [6] and [14], where the existence and uniqueness of near-equilibrium oscillation were studied. Except for the work mentioned above, the suspension bridge system governed by the coupled nonlinear beam and wave equations has not yet received in-depth study in the existing literature.
In this paper, we study the following suspension bridge model proposed by Lazer and McKenna in [10]

\[
\begin{align*}
& m_u u_{tt} - Q u_{xx} - K (w - u)^+ = m_c g + \varepsilon h_1 (x, t), \quad 0 < x < L, \\
& m_b w_{tt} + EI u_{xxxx} + K (w - u)^+ = m_b g + \varepsilon h_2 (x, t), \quad 0 < x < L, \\
& u(0, t) = u(L, t) = 0, \\
& w(0, t) = w(L, t) = 0, \quad w_{xx}(0, t) = w_{xx}(L, t) = 0,
\end{align*}
\]

which describes oscillations in a simplified suspension bridge configuration: the roadbed of length \( L \) is modeled by a horizontal vibrating beam with both ends being simply supported; the supporting cable of length \( L \) is modeled by a horizontal vibrating string with both ends being fixed; and the vertical stays connecting the roadbed to the supporting cable are modeled by one-sided springs which resist expansion but do not resist compression. In system (1.1), \( u(x, t) \) and \( w(x, t) \) denote the downward deflections of the cable and the roadbed, respectively; \( (w - u)^+ = \max\{w - u, 0\} \); \( m_c \) and \( m_b \) are the mass densities of the cable and the roadbed, respectively; \( Q \) is the coefficient of cable tensile strength; \( EI \) is the roadbed flexural rigidity; \( K \) is the Hooke’s constant of the stays; \( h_1 \) and \( h_2 \) represent the external periodic aerodynamic forces; and, \( \varepsilon \) is a parameter. We are interested in periodic oscillations in (1.1), which are symmetric about \( x = L/2 \),

\[
\begin{align*}
& u(x, t + T) = u(x, t), \quad w(x, t + T) = w(x, t), \quad 0 \leq x \leq L, \\
& u(x, t) = u(L - x, t), \quad w(x, t) = w(L - x, t), \quad 0 \leq x \leq L,
\end{align*}
\]

where \( T \) is the period of periodic oscillations. By rescaling and translating \( x \) and \( t \), system (1.1) with (1.2) can be written in an equivalent form

\[
\begin{align*}
& m_c u_{tt} - Q u_{xx} - K (w - u)^+ = m_c g + \varepsilon h_1 (x, t), \quad -\pi/2 < x < \pi/2, \\
& m_b w_{tt} + EI u_{xxxx} + K (w - u)^+ = m_b g + \varepsilon h_2 (x, t), \quad -\pi/2 < x < \pi/2, \\
& u(-\pi/2, t) = u(\pi/2, t) = 0, \\
& w(-\pi/2, t) = w(\pi/2, t) = 0, \quad w_{xx}(-\pi/2, t) = w_{xx}(\pi/2, t) = 0, \\
& u(-x, t) = u(x, t), \quad w(-x, t) = w(x, t), \quad 0 \leq x \leq \pi/2, \\
& u(x, t + \pi) = u(x, t), \quad w(x, t + \pi) = w(x, t), \quad -\pi/2 \leq x \leq \pi/2,
\end{align*}
\]

where \( h_1(x, t) \) and \( h_2(x, t) \) are \( \pi \)-periodic functions in \( t \).

We have studied in [4] nonlinear periodic oscillations of system (1.3) by assuming \( h_1 \) and \( h_2 \) being some special eigenfunctions of the beam and wave operators. By letting \( h_1 \) and \( h_2 \) be any \( H^2 \)-functions and by applying the Mountain Pass Theorem, we have shown in [5] that system (1.3) has at least two periodic solutions.

By assuming \( h_1 \) and \( h_2 \) to be any \( L^2 \)-functions, the objective of this paper is to study nonlinear periodic oscillations of system (1.3) by using the Leray-Schauder degree theory, which is motivated by an important paper [12] by McKenna and Walter who studied the single Lazer-McKenna suspension bridge equation by using the Leray-Schauder degree theory. It is proved in this paper that there exists a constant \( \varepsilon_0 > 0 \) such that system (1.3) has at least two periodic solutions if \( |\varepsilon| < \varepsilon_0 \) (see Theorem 2.2).

2. NONLINEAR PERIODIC OSCILLATIONS

To investigate the suspension bridge system (1.3), we assume throughout this paper that

\[
Q \leq m_c, \quad EI \leq m_b,
\]
which hold naturally for suspension bridges in civil engineering applications. Define the wave operator $L_1$ by

$$\begin{cases}
L_1 u = m_e u_{tt} - Q u_{xx}, \\
u(-\pi/2, t) = u(\pi/2, t) = 0, \\
u(x, t) = u(-x, t), \quad u(x, t + \pi) = u(x, t).
\end{cases}$$

Define the beam operator $L_2$ by

$$\begin{cases}
L_2 w = m_b w_{tt} + EI w_{xxxx}, \\
w(-\pi/2, t) = w(\pi/2, t) = 0, \\
w_{xx}(-\pi/2, t) = w_{xx}(\pi/2, t) = 0, \\
w(x, t) = w(-x, t), \quad w(x, t + \pi) = w(x, t).
\end{cases}$$

Denote by $\{\lambda_{mn}\}$ the eigenvalues of $L_1$ and by $\{\mu_{mn}\}$ the eigenvalues of $L_2$. Then it follows from a direct calculation that

$$\begin{align*}
\lambda_{mn} &= Q(2n + 1)^2 - 4m_e m^2, \quad m, n = 0, 1, 2, \ldots, \\
\mu_{mn} &= EI(2n + 1)^4 - 4m_b m^2, \quad m, n = 0, 1, 2, \ldots.
\end{align*}$$

The eigenfunctions of $L_1$ corresponding to eigenvalue $\lambda_{mn}$ are the same as that of $L_2$ corresponding to eigenvalue $\mu_{mn}$, which are given by

$$\begin{align*}
\varphi_{mn}(x, t) &= \cos(2n + 1)x, \quad n \geq 0, \\
\varphi_{mn}(x, t) &= \cos(2n + 1)x \cos 2mt, \quad m \geq 1, n \geq 0, \\
\psi_{mn}(x, t) &= \cos(2n + 1)x \sin 2mt, \quad m \geq 1, n \geq 0.
\end{align*}$$

Let $\Omega = (-\pi/2, \pi/2) \times (-\pi/2, \pi/2)$, and $H$ be the Hilbert space defined by

$$H = \{u \in L^2(\Omega) \mid u(-x, t) = u(x, t)\}.$$

It is easy to check that the set of eigenfunctions $\{\varphi_{mn}, \psi_{mn}\}$ is an orthogonal basis of $H$. Assume throughout this paper that the material parameters $m_e$, $m_b$, $Q$ and $EI$ are chosen such that

$$\begin{align*}
\left(\frac{\sqrt{Q}}{m_e}\right) \text{ and } \left(\sqrt{\frac{EI}{m_b}}\right) \text{ are rational numbers; } \\
\lambda_{mn} &= Q(2n + 1)^2 - 4m_e m^2 \neq 0; \quad \lambda_{mn} + \mu_{mn} \neq 0, \quad \mu_{mn} = EI(2n + 1)^4 - 4m_b m^2 \neq 0; \quad m, n \geq 1.
\end{align*}$$

By the assumption (2.3), $L_1$, $L_2$ and $L_1 + L_2$ are invertible in $H$. The assumption of both $\sqrt{Q/m_e}$ and $\sqrt{EI/m_b}$ being rational is necessary due to the known fact that certain number theoretical difficulties may be encountered [5]. Define

$$A = L_2 L_1 (L_1 + L_2)^{-1}.$$

The eigenvalues of $A$ are given by

$$\sigma_{mn} = \frac{\lambda_{mn} \mu_{mn}}{\lambda_{mn} + \mu_{mn}},$$

where the corresponding eigenfunctions are given by $\{\varphi_{mn}, \psi_{mn}\}$. Under assumption (2.3) and by using (2.2), the following mapping properties of $L_1$, $L_2$ and $A$ were proved in [6].

**Lemma 2.1.** Let $\beta \in \mathbb{R}$ and $\beta \neq -\sigma_{mn}$, and $s \geq 0$. Assume that (2.3) holds. Then

(a) $L_1^{-1}$ is a bounded linear operator from $H^s(\Omega) \cap H$ to $H^{s+1}(\Omega) \cap H$;

(b) $L_2^{-1}$ is a bounded linear operator from $H^s(\Omega) \cap H$ to $H^{s+2}(\Omega) \cap H$; and

(c) $(A + \beta)^{-1}$ is a bounded linear operator from $H^s(\Omega) \cap H$ to $H^{s+1}(\Omega) \cap H$.  

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
By Lemma 2.1, it is easy to show that $L_1$, $L_2$ and $A$ have compact inverses in $H$. Under assumption (2.1), one can check easily
\begin{equation}
\sigma_{20} < \sigma_{10} < 0 < \sigma_{00}.
\end{equation}
Assume throughout this paper that
\begin{equation}
\mu_0 \text{ the only eigenvalue of } A \text{ in the interval } (\sigma_{20}, \sigma_{00}) \text{ is } \sigma_{10}.
\end{equation}
By using the above notations and by restricting the domain of $(u, w)$ to $\Omega$, system (1.3) can be written as
\begin{equation}
\begin{cases}
L_1u - K(w - u)^+ = m_c g + \varepsilon h_1, \\
L_2w + K(w - u)^+ = m_b g + \varepsilon h_2.
\end{cases}
\end{equation}
By applying the Mountain Pass Theorem to a dual variational formulation of (2.6), it was proved in [5] that if $(h_1, h_2) \in (H^2(\Omega) \cap H) \times (H^2(\Omega) \cap H)$, and if $-\sigma_{10} < K < \Delta$ where
\begin{equation}
-\sigma_{10} < \Delta = \frac{\sigma_{20} + \sqrt{\sigma_{20}^2 + 8\sigma_{10}\sigma_{20}}}{2} < -\sigma_{20},
\end{equation}
then there exists an $\varepsilon_0 > 0$ such that (2.6) admits at least two solutions in $H^3(\Omega) \times H^4(\Omega)$ if $|\varepsilon| < \varepsilon_0$. By relaxing the assumptions on $(h_1, h_2)$ and $K$, we prove in this paper the following main result.

**Theorem 2.2.** Let $(h_1, h_2) \in H \times H$ with $\|h_1\| = 1$ and $\|h_2\| = 1$. If $-\sigma_{10} < K < -\sigma_{20}$, then there exists an $\varepsilon_0 > 0$ such that if $|\varepsilon| < \varepsilon_0$, then (2.6) admits at least two solutions in $(H^2(\Omega) \cap H) \times (H^2(\Omega) \cap H)$. Consequently, system (1.3) admits at least two $\pi$-periodic solutions.

In this paper, $\| \cdot \|$ denotes the usual norm of $L^2(\Omega)$. To prove the existence of multiple solutions of (2.6), we first derive an equivalent system of (2.6). From (2.6), one has

\begin{equation}
L_1u + L_2w = (m_c + m_b)g + \varepsilon(h_1 + h_2).
\end{equation}

By applying $L_1^{-1}L_2^{-1}$ to both sides of this equation, we have

\begin{equation}
L_2^{-1}u + L_1^{-1}w = L_1^{-1}L_2^{-1}[(m_c + m_b)g + \varepsilon(h_1 + h_2)].
\end{equation}

Let $\bar{w} = L_1^{-1}w$ and $\bar{u} = L_2^{-1}u$, then $u = L_2\bar{u}$, $w = L_1\bar{w}$, and

\begin{equation}
\bar{w} + \bar{u} = L_1^{-1}L_2^{-1}[(m_c + m_b)g + \varepsilon(h_1 + h_2)].
\end{equation}

By substituting them into the second equation of (2.6), we obtain

\begin{equation}
L_2L_1\bar{w} + K [(L_1 + L_2)\bar{w} - (m_c + m_b)gL_1^{-1}(1) - \varepsilon L_1^{-1}(h_1 + h_2)]^+ = m_b g + \varepsilon h_2.
\end{equation}

Let $v = (L_1 + L_2)\bar{w}$, $f_0 = (m_c + m_b)gL_1^{-1}(1) \in H$ and $f_1 = L_1^{-1}(h_1 + h_2) \in H$, then the above equation can be written as

\begin{equation}
Av + K [v - f_0 - \varepsilon f_1]^+ = m_b g + \varepsilon h_2.
\end{equation}

Note that the relation between $w - u$ and $v$ is given by

\begin{equation}
w - u = L_1\bar{w} - L_2\bar{u} = v - f_0 - \varepsilon f_1.
\end{equation}
By substituting the above relation into (2.6), we obtain
\[ u = L_1^{-1} \left[ K (v - f_0 - \varepsilon f_1)^+ + m_c g + \varepsilon h_1 \right], \]
(2.9)
\[ w = L_2^{-1} \left[ -K (v - f_0 - \varepsilon f_1)^+ + m_b g + \varepsilon h_2 \right]. \]

If \( v \in H \) is a solution of (2.7), then \((u, w) \in (H^1(\Omega) \cap H) \times (H^2(\Omega) \cap H)\) given by (2.9) is a solution of (2.6), where the regularity of (2.7) satisﬁes for \( K \) and \( v \). We prove (2.7) admits at least two solutions in Lemma 2.3. Therefore, to study the multiple solutions of (2.7) becomes to study the multiple solutions of (2.7). We prove (2.7) admits at least two solutions in \( H \) by using the Leray-Schauder degree theory.

We need to establish several useful lemmas. Consider the equilibrium oscillation in system (2.5) determined by the following equation,
\[ \begin{aligned}
&-Qu_{xx} - K (w - u)^+ = m_c g, \quad -\pi/2 < x < \pi/2, \\
&EI w_{xxx} + K (w - u)^+ = m_b g, \quad -\pi/2 < x < \pi/2, \\
&u(-\pi/2) = u(\pi/2) = 0, \\
&w(-\pi/2) = w(\pi/2) = 0, \\
&w_{xx}(-\pi/2) = w_{xx}(\pi/2) = 0, \\
&w(-x) = w(x), \quad 0 \leq x \leq \pi/2.
\end{aligned} \]
(2.10)

**Lemma 2.3.** For any given \( K > 0 \), there exists a \( \mu_0 > 0 \), which depends only on \( K, Q \) and \( EI \), such that if \( m_c / m_b < \mu_0 \), then (2.10) admits a \( C^\infty \)-solution \((u_e, w_e)\) satisfying \( u'_e(-\pi/2) - u'_e(-\pi/2) > 0, w'_e(-\pi/2) - w'_e(\pi/2) < 0, \) and \( w_e(x) - u_e(x) > 0 \) for \(-\pi/2 < x < \pi/2\).

Note that \((u_e, w_e)\) obviously satisfies (2.9) with \( \varepsilon = 0 \),
\[ \begin{aligned}
&L_1 u_e - K (w_e - u_e)^+ = m_c g, \\
&L_2 w_e + K (w_e - u_e)^+ = m_b g.
\end{aligned} \]
(2.11)

The proof of Lemma 2.3 and the explicit expressions of \( \mu_0 \) and \((u_e, w_e)\) can be found in [3]. Thus by (2.5), \( v_0 = w_e - u_e + f_0 \in C^\infty(\Omega) \cap H \) satisfying
\[ Av_0 + K [v_0 - f_0]^+ = m_b g, \]
(2.12)
and \( v_0(x, t) - f_0(x, t) = w_e(x) - u_e(x) > 0 \) for \(-\pi/2 < x < \pi/2, \) and \( v_0(\pm\pi/2, t) - f_0(\pm\pi/2, t) = 0. \)

**Lemma 2.4.** If \(-\sigma_00 < K < -\sigma_20, \) then the following equation
\[ Av + K v^+ = 0 \]
(2.13)
admits only the trivial solution \( v = 0 \) in \( H \).

The proof of Lemma 2.4 can be found in [3]. The next lemma establishes an a priori bound for solutions of (2.7) in \( H \).

**Lemma 2.5.** Let \((h_1, h_2) \in H \times H \) with \( \|h_1\| = 1 \) and \( \|h_2\| = 1. \) Let \( \alpha > 0 \) be a given small real number. Then there exists an \( R_0 > 0 \) depending only on \( \alpha \) and \((h_1, h_2) \) such that if \(-\sigma_00 + \alpha \leq K \leq -\sigma_20 - \alpha \) and \( \varepsilon \in [-1, 1], \) any solution \( v \) of (2.7) satisfies \( v \leq R_0. \)

**Proof.** Assume the conclusion is not true, then there exist sequences of \( \{\varepsilon_n\}, \{K_n\} \) and \( \{v_n\} \) such that \( K_n \in [-\sigma_00 + \alpha, -\sigma_20 - \alpha], \) \( \varepsilon_n \in [-1, 1], \) \( \|v_n\| \to \infty, \) and
\[ Av_n + K_n [v_n - f_0 - \varepsilon_n f_1]^+ = m_b g + \varepsilon_n h_2. \]
Let $\bar{v}_n = \frac{v_n}{\|v_n\|}$, then
\[
\bar{v}_n = A^{-1}\left\{ \frac{m_{10}g + \varepsilon h_2}{\|v_n\|} - K_n \left[ \bar{v}_n - \frac{f_0}{\|v_n\|} - \varepsilon_n f_1 \right] \right\}.
\]

Since $A^{-1}$ is compact in $H$, there is a subsequence of $\{\bar{v}_n\}$; denote it again by $\{\bar{v}_n\}$, such that $\bar{v}_n \to \bar{v}_0$, $K_n \to K_0$ and $\varepsilon_n \to \varepsilon_0$, and
\[
\bar{v}_0 = A^{-1}\left\{ -K_0[\bar{v}_0]^+ \right\},
\]
where $K_0 \in [-\sigma_{00} + \alpha, -\sigma_{20} - \alpha] \subset (-\sigma_{00}, -\sigma_{20})$, $\varepsilon_0 \in [-1,1]$ and $\|\bar{v}_0\| = 1$. However, by Lemma 2.4, the above equation admits only the trivial solution $\bar{v}_0 = 0$, which contradicts $\|\bar{v}_0\| = 1$. \qed

**Lemma 2.6.** Let $(h_1, h_2) \in H \times H$ with $\|h_1\| = 1$ and $\|h_2\| = 1$. Let $\alpha > 0$ be a given small real number, and let $R_0$ be defined as in Lemma 2.5. If $K \in [-\sigma_{00} + \alpha, -\sigma_{20} - \alpha]$ and $\varepsilon \in [-1,1]$, then
\[
d_{LS}\left( v - A^{-1}\left\{ m_{10}g + \varepsilon h_2 - K [v - f_0 - \varepsilon f_1]^+ \right\}, B_R(0), 0 \right) = 1,
\]
for all $R \geq R_0$, where $d_{LS}$ denotes the Leray-Schauder degree, and $B_R(0) = \{v \in H : \|v\| \leq R\}$.

**Proof.** Let $R \geq R_0$. For any $K \in [-\sigma_{00} + \alpha, -\sigma_{20} - \alpha]$, define
\[
\psi_K(v) = A^{-1}\left\{ m_{10}g + \varepsilon h_2 - K [v - f_0 - \varepsilon f_1]^+ \right\}.
\]
From Lemma 2.5, any solution $v$ of (2.7) is bounded and satisfies $\|v\| < R_0$. Thus $0 \not\in (I - \psi_K)(\partial B_R(0))$. Since $A^{-1}$ is compact in $H$, $\psi_K$ defines a homotopy of compact transformation on $B_R(0)$. Note that
\[
v - \psi_0(v) = v - A^{-1}(m_{10}g + \varepsilon h_2)
\]
which is simply a translation of the identity, and $\|A^{-1}(m_{10}g + \varepsilon h_2)\| < R_0$ by Lemma 2.3. Then by using the properties of the Leray-Schauder degree [11], we have
\[
d_{LS}(v - \psi_0(v), B_R(0), 0) = 1.
\]
By the invariance of the Leray-Schauder degree under homotopy [11], we have
\[
d_{LS}(v - \psi_K(v), B_R(0), 0) = 1,
\]
for $K \in [-\sigma_{00} + \alpha, -\sigma_{20} - \alpha]$. \qed

The next important lemma was first introduced and proved by McKenna and Walter in [13].

**Lemma 2.7.** Let $D$ be a compact set in $L^2(\Omega)$, and $\phi \in L^2(\Omega)$ be positive almost everywhere. Then there exists a modulus of continuity $\delta$ depending only on $D$ and $\phi$ such that
\[
\|(n\psi - \phi)^+\| \leq \eta \delta(\eta), \quad \text{for any } \eta > 0 \text{ and } \psi \in D.
\]

Lemma 2.7 plays an important role in proving the following lemma.

**Lemma 2.8.** Let $(h_1, h_2) \in H \times H$ with $\|h_1\| = 1$ and $\|h_2\| = 1$. If $-\sigma_{10} < K < -\sigma_{20}$, then there exist $\gamma > 0$ and $\varepsilon_0 > 0$ such that
\[
d_{LS}\left( v - A^{-1}\left\{ m_{10}g + \varepsilon h_2 - K [v - f_0 - \varepsilon f_1]^+ \right\}, B_\gamma(v_0), 0 \right) = -1,
\]
for $|\varepsilon| \leq \varepsilon_0$, where $v_0$ is defined in (2.7).
Proof. For any $\lambda \in [0, 1]$, define
\[
h_\lambda(v) = A^{-1} \left\{ m_b g - K(v - f_0) + \lambda \left[ \varepsilon(h_2 + K f_1) - K(v - f_0 - \varepsilon f_1)^- \right] \right\},
\]
where $w^- = \max\{-w, 0\}$ and $w = w^+ - w^-$. Then
\[
h_0(v) = A^{-1} \left\{ m_b g - K(v - f_0) \right\},
\]
\[
h_1(v) = A^{-1} \left\{ m_b g + \varepsilon h_2 - K(v - f_0 - \varepsilon f_1)^+ \right\}.
\]
Since $A^{-1}$ is compact in $H$, $h_\lambda$ defines a homotopy of compact transformation on $B_\gamma(v_0)$ in $H$ for any $\gamma > 0$. If, for some $\gamma > 0$, $h_\lambda$ satisfies
\[
0 \not\in (I - h_\lambda)(\partial B_\gamma(v_0)), \quad \forall \lambda \in [0, 1],
\]
then, by the invariance of the Leray-Schauder degree under homotopy [11], we have
\[
d_{LS} \left( v - A^{-1} \left\{ m_b g + \varepsilon h_2 - K[v - f_0 - \varepsilon f_1]^+ \right\}, B_\gamma(v_0), 0 \right)
= d_{LS} \left( v - h_1(v), B_\gamma(v_0), 0 \right)
= d_{LS} \left( v - h_0(v), B_\gamma(v_0), 0 \right)
= d_{LS} \left( v - A^{-1} \left\{ m_b g - K(v - f_0) \right\}, B_\gamma(v_0), 0 \right).
\]
By Lemma 2.3 and (2.12), it is easy to verify that $v_0$ is the unique solution of
\[
Av + K[v - f_0] = m_b g,
\]
because $-\sigma_{10} < K < -\sigma_{20}$. Thus
\[
d_{LS} \left( v - A^{-1} \left\{ m_b g - K(v - f_0) \right\}, B_\gamma(v_0), 0 \right) = d_{LS} \left( (I + KA^{-1})v, B_\gamma(0), 0 \right).
\]
By (2.3), it is easy to check that the eigenvalues of $I + KA^{-1}$ are given by $\rho_{mn} = 1 + \frac{K}{\sigma_{mn}} \neq 0$ whose corresponding eigenfunctions are given by $\{\varphi_{mn}, \psi_{mn}\}$. By (2.6) and the assumption $-\sigma_{10} < K < -\sigma_{20}$, we have $\rho_{10} < 0$ and $\rho_{mn} > 0$ for the rest of the eigenvalues of $I + KA^{-1}$. Thus, for such a type of linear operators, it is well known [11] that
\[
d_{LS} \left( (I + KA^{-1})v, B_\gamma(0), 0 \right) = -1.
\]
Therefore, we have
\[
d_{LS} \left( v - A^{-1} \left\{ m_b g + \varepsilon h_2 - K[v - f_0 - \varepsilon f_1]^+ \right\}, B_\gamma(v_0), 0 \right) = -1,
\]
provided (2.14) is proved to be true.

In the rest of the proof, we show that there exist $\varepsilon_0 > 0$ and $\gamma > 0$ such that (2.14) is true when $|\varepsilon| \leq \varepsilon_0$.

Under assumptions (2.1) and (2.3), it is straightforward to check that $0 < \sigma_{00} < -\sigma_{10}$, hence $\|A^{-1}\| = 1/\sigma_{00}$. Let $D$ be the closure of $A^{-1}(B_1(0))$. Thus $D$ is compact in $H$. Assume there is a $v \in H$ such that $\|v - v_0\| = \gamma$ and $v - h_\lambda(v) = 0$, then
\[
Av - \left\{ m_b g - K(v - f_0) + \lambda \left[ \varepsilon(h_2 + K f_1) - K(v - f_0 - \varepsilon f_1)^- \right] \right\} = 0.
\]
Let $\phi = v - v_0$. Then $\|\phi\| = \gamma$. By using (2.12), it follows from (2.15) that
\[
A\phi = -K\phi + \lambda \left[ \varepsilon(h_2 + K f_1) - K(v_0 - f_0 + \phi - \varepsilon f_1)^- \right] - (\phi - \varepsilon f_1)^-.
\]
Since $v_0 - f_0 \geq 0$ on $\Omega$, we have
\[
0 \leq (v_0 - f_0 + \phi - \varepsilon f_1)^- \leq (\phi - \varepsilon f_1)^-.
\]
Thus, for any \( \lambda \in [0, 1] \),
\[
\| -K\phi + \lambda \varepsilon(h_2 + Kf_1) - K(v_0 - f_0 + \phi - \varepsilon f_1) \| \leq |\varepsilon|(1 + 2K\|f_1\|) + 2K\gamma.
\]
Let \( \varepsilon_1 = \frac{\gamma}{1 + 2K\|f_1\|} \). By (2.16) and the above estimate, we then have, for any \(|\varepsilon| \leq \varepsilon_1\),
\[
\phi \in (1 + 2K)\gamma D.
\]
Rewrite (2.16) as
\[
\phi + KA^{-1}\phi = \lambda A^{-1} \varepsilon(h_2 + Kf_1) - K(v_0 - f_0 + \phi - \varepsilon f_1).\]
By (2.15) and the assumption \(-\sigma_{10} < K < -\sigma_{20}\), we have
\[
\alpha \overset{\text{def}}{=} \inf_{\psi \in H, \|\psi\|=1} \|\psi + KA^{-1}\phi\| > 0.
\]
\(\alpha\) depends only on \(K\) and \(A\). Since \(\|\phi\| = \gamma\), the left-hand side of (2.18) satisfies
\[
(2.17) \quad \|\phi + KA^{-1}\phi\| \geq \gamma\alpha.
\]
For the right-hand side of (2.18), we obtain
\[
\|\lambda A^{-1} \varepsilon(h_2 + Kf_1) - K(v_0 - f_0 + \phi - \varepsilon f_1)\|
\leq \frac{|\varepsilon|(1 + 2K\|f_1\|)}{\sigma_{00}} + \frac{K}{\sigma_{00}} \|\phi + v_0 - f_0\|,
\]
where we have used \(0 \leq |u + w| \leq u^- + w^-\) and \(0 \leq w \leq |w|\). Note that \(D\) is compact in \(H\), and \((v_0 - f_0)(x,t) > 0\) for \(-\pi/2 < x < \pi/2\) and \((v_0 - f_0)(\pm\pi/2, t) = 0\) from (2.12). By Lemma 2.7, there exists a modulus of continuity \(\delta\) depending only on \(D\) and \(v_0 - f_0\) such that
\[
\|\eta\psi - (v_0 - f_0)\| \leq \eta\delta(\eta), \text{ for any } \eta > 0 \text{ and } \psi \in D.
\]
Thus, by using (2.17), we have
\[
\|\phi + v_0 - f_0\| = \|\phi - (v_0 - f_0)\| \leq (1 + 2K)\gamma\delta((1 + 2K)\gamma).
\]
Then
\[
\|\lambda A^{-1} \varepsilon(h_2 + Kf_1) - K(v_0 - f_0 + \phi - \varepsilon f_1)\|
\leq \frac{|\varepsilon|(1 + 2K\|f_1\|)}{\sigma_{00}} + \frac{(1 + 2K)\gamma\delta((1 + 2K)\gamma)}{\sigma_{00}}.
\]
Since \(\delta(\eta)\) is a modulus of continuity, one can choose \(\gamma\) small enough such that
\[
\frac{(1 + 2K)K}{\sigma_{00}} \delta((1 + 2K)\gamma) < \frac{\alpha}{4}.
\]
Then we fix \(\gamma\), and let
\[
\varepsilon_0 = \min\left\{ \frac{\gamma}{1 + 2K\|f_1\|}, \frac{\alpha\gamma\sigma_{00}}{2(1 + 2K\|f_1\|)} \right\} \leq \varepsilon_1.
\]
For any \(|\varepsilon| \leq \varepsilon_0\), we then have
\[
(2.20) \quad \|\lambda A^{-1} \varepsilon(h_2 + Kf_1) - K(v_0 - f_0 + \phi - \varepsilon f_1)\| \leq \frac{3\alpha\gamma}{4}.
\]
Since the left-hand side of (2.18) satisfies (2.19), and the right-hand side of (2.18) satisfies (2.20) for any $|\varepsilon| \leq \varepsilon_0$, there is no such $\varphi \in H$ satisfying (2.18). Hence (2.19) has no solution in $H$ if $|\varepsilon| \leq \varepsilon_0$. Therefore, (2.14) is proved. \hfill \square

Proof of Theorem 2.2. Since (2.15) is equivalent to (2.17), one only needs to show that (2.7) admits at least two solutions in $H$. For any $-\sigma_{10} < K < -\sigma_{20}$, it follows from Lemma 2.6 that there exists an $R_0 > 0$ such that, for $R \geq R_0$,
\[
d_{LS} \left( v - A^{-1} \left\{ m_k g + \varepsilon h_2 - K[v - f_0 - \varepsilon f_1]^{+} \right\}, B_R(0), 0 \right) = 1.
\]
By Lemma 2.8, there exist $\gamma > 0$ and $\varepsilon_0 > 0$ such that
\[
d_{LS} \left( v - A^{-1} \left\{ m_k g + \varepsilon h_2 - K[v - f_0 - \varepsilon f_1]^{+} \right\}, B_{\gamma}(v_0), 0 \right) = -1,
\]
for $|\varepsilon| \leq \varepsilon_0$. By choosing $R \geq R_0$ so large that $B_R(0) \supset B_{\gamma}(v_0)$, we then have
\[
d_{LS} \left( v - A^{-1} \left\{ m_k g + \varepsilon h_2 - K[v - f_0 - \varepsilon f_1]^{+} \right\}, B_R(0) \setminus B_{\gamma}(v_0), 0 \right) = 2.
\]
Therefore, (2.7) admits at least two solutions in $H$, one in $B_{\gamma}(v_0)$ and one in $B_R(0) \setminus B_{\gamma}(v_0)$. Consequently, (2.6) admits at least two solutions in $H \times H$. \hfill \square

From the above proof of Theorem 2.2 we observe that one solution $v_1$ of (2.7) is in $B_{\gamma}(v_0)$, which is very close to $v_0$. In other words, (2.6) admits a solution corresponding to $v_1$ by (2.9), which is in fact a near-equilibrium solution. Such a near-equilibrium solution can be proved also by the Banach fixed point theorem \[5\]. On the other hand, the above proof of Theorem 2.2 shows that (2.7) admits another solution $v_2$ in $B_R(0) \setminus B_{\gamma}(v_0)$, which implies $|v_2 - v_0| > \gamma$. In other words, (2.6) admits a solution corresponding to $v_2$ by (2.9), which is not near the equilibrium solution $(u_0, w_0)$. In this sense, such a solution can be understood as a large amplitude oscillation of system (2.6).

As a final remark, we point out that assumption (2.1) plays a key role in proving Lemma 2.4 which plays a key role in establishing \textit{a priori} bound for solutions of (2.7) in $H$ (see Lemma 2.5), and in proving that the functional corresponding to the variational formulation of system (2.7) satisfies the Palais-Smale condition in \[5\]. (2.1) is a sufficient condition, and can be relaxed certainly a little bit further. However, a relaxation of (2.1) may create some technical difficulties particularly in proving Lemma 2.4.
