

OPPENHEIM CONJECTURE FOR PAIRS CONSISTING OF A LINEAR FORM AND A QUADRATIC FORM

ALEXANDER GORODNIK

ABSTRACT. Let Q be a nondegenerate quadratic form and L a nonzero linear form of dimension $d > 3$. As a generalization of the Oppenheim conjecture, we prove that the set $\{(Q(x), L(x)) : x \in \mathbb{Z}^d\}$ is dense in \mathbb{R}^2 provided that Q and L satisfy some natural conditions. The proof uses dynamics on homogeneous spaces of Lie groups.

1. INTRODUCTION

It was proved by Margulis [Ma89] (see [Ma97] for an up-to-date survey) that if Q is a real indefinite nondegenerate quadratic form of dimension $d \geq 3$ which is not proportional to a rational form, then $\{Q(x) : x \in \mathbb{Z}^d\}$ is dense in \mathbb{R} . A similar problem was considered for pairs (Q, L) , where Q is a quadratic form as above, and L is a nonzero linear form. The known results are limited to dimension 3. It was proved by Dani and Margulis [DM90] that $\{(Q(x), L(x)) : x \in \mathbb{Z}^3\}$ is dense in \mathbb{R}^2 if no nonzero linear combination of Q and L^2 is rational, and the plane $\{L = 0\}$ is tangent to the surface $\{Q = 0\}$. Clearly, the first condition is necessary for the density to hold. The second condition guarantees that the stabilizer in $\mathrm{SL}(3, \mathbb{R})$ of the pair (Q, L) is unipotent, so that the results on orbits of unipotent flows can be used. One can hope to remove the second condition. However, Dani proved in [Da00] that if the surface $\{Q = 0\}$ and the plane $\{L = 0\}$ intersect transversally, the density can fail for a set pairs of full Hausdorff dimension. On the other hand, it is easy to see using Moore ergodicity criterion that the density holds for a set of pairs of full measure provided that the surfaces $\{Q = 0\}$ and $\{L = 0\}$ have nonzero intersection.

Denote by $\mathcal{P}(\mathbb{Z}^d)$ the set of primitive integer vectors in \mathbb{Z}^d . The results mentioned above still hold when \mathbb{Z}^d is replaced by $\mathcal{P}(\mathbb{Z}^d)$.

In this paper we prove a density result for pairs consisting of a linear form and a quadratic form of dimension $d \geq 4$:

Theorem 1. *Let Q be a nondegenerate quadratic form, and let L be a nonzero linear form in dimension $d \geq 4$. Suppose that*

- (1) $Q|_{L=0}$ is indefinite.
- (2) For every $(\alpha, \beta) \neq (0, 0)$, with $\alpha, \beta \in \mathbb{R}$, $\alpha Q + \beta L^2$ is not rational.

Then $\{(Q(x), L(x)) : x \in \mathcal{P}(\mathbb{Z}^d)\}$ is dense in \mathbb{R}^2 .

This article is a part of the author's Ph.D. thesis at Ohio State University done under the supervision of Professor Bergelson.

For $d = 3$, condition (1) implies that the surfaces $\{Q = 0\}$ and $\{L = 0\}$ intersect transversally. Therefore, it follows from the result of Dani [Da00] mentioned above that the analogue of Theorem 1 does not hold for $d = 3$.

It is easy to see that the second condition is necessary for the conclusion of the theorem to hold. A condition similar to the first condition is required to ensure that

$$\{(Q(x), L(x)) : x \in \mathbb{R}^d\} = \mathbb{R}^2.$$

It is possible that the first condition can be weakened (see Conjecture 15 below).

2. CANONICAL FORMS

Let $Q_i, i = 1, 2$, be quadratic forms, and let $L_i, i = 1, 2$, be linear forms of dimension d . We say that the pairs (Q_1, L_1) and (Q_2, L_2) are *equivalent* if $Q_1(x) = \lambda Q_2(g \cdot x)$ and $L_1(x) = \mu L_2(g \cdot x)$ for some $\lambda, \mu \in \mathbb{R} - \{0\}$ and $g \in \text{SL}(n, \mathbb{R})$. That is, they can be transformed into each other by a linear change of coordinates and scaling.

Proposition 2. *Every pair (Q, L) , where Q is a nondegenerate quadratic form and L is a nonzero linear form, is equivalent to one and only one of the following pairs:*

- (I) $(x_1^2 + \dots + x_s^2 - x_{s+1}^2 - \dots - x_d^2, x_d)$, where $s = 1, \dots, d$.
- (II) $(x_1^2 + \dots + x_s^2 - x_{s+1}^2 - \dots - x_{d-2}^2 + x_{d-1}x_d, x_d)$, where $s = 0, \dots, \lfloor \frac{d-2}{2} \rfloor$.

Proof. Without loss of generality, $L(x) = x_d$. Applying a linear transformation in x_1, \dots, x_{d-1} , we transform Q to the form

$$\sum_{i \leq k} \pm x_i^2 + \left(\sum_j a_j x_j \right) x_d \text{ for some } k \leq d - 1.$$

Using linear transformations $x_i \rightarrow x_i \pm \frac{a_i}{2} x_d$ for $i \leq k$, we can make $a_i = 0$ for $i \leq k$. If $a_i = 0$ for all $i \neq d$, then $k = d - 1$ because Q is nondegenerate. Thus, we are in the case (I). Let $a_l \neq 0$ for some $l < d$. Making a linear change of variables $x_l \leftarrow \sum_j a_j x_j$, we get

$$Q = \sum_{i \leq k} \pm x_i^2 + x_l x_d.$$

Since Q is nondegenerate, $k = d - 2$ and $l = d - 1$. This is the case (II). Note that a pair (Q, L) is of type (I) iff $Q + \alpha L^2$ is degenerate for some $\alpha \in \mathbb{R}$. In particular, this shows that pairs of type (I) and (II) are not equivalent. Signatures of quadratic forms Q and $Q|_{L=0}$ are invariants of equivalence with one possible exception that pairs with signatures $(s, d - s)$ and $(d - s, s)$ could be equivalent. For example, pairs of type (I) with $s = 0$ and $s = d$ are equivalent. Let (Q, L) be as in (I) with $s = i$ for $i \neq 0, d$. Then $Q|_{L=0}$ has signature $(i, d - i - 1)$. On the other hand, when $s = d - i$, $Q|_{L=0}$ has signature $(d - i, i - 1)$. Clearly, these two cases are not equivalent unless $n = 2i$, and they coincide. When (Q, L) is of type (II), it is easy to see that the cases $s = i$ and $s = d - 2 - i$ are equivalent for $i = 0, \dots, d - 2$. This finishes the proof. □

Using the explicit formulas for canonical forms, it is easy to prove the following lemma.

Lemma 3. *Let Q be a nondegenerate quadratic form, and let L be a nonzero linear form such that $Q|_{L=0}$ is indefinite. Then*

$$\{(Q(x), L(x)) : x \in \mathbb{R}^d\} = \mathbb{R}^2.$$

3. REDUCTION TO LOWER DIMENSION

In this section, we prove Proposition 4, which reduces the proof of Theorem 1 to the case of dimension 4.

Proposition 4. *Let (Q, L) satisfy the conditions of Theorem 1. If the dimension of the space is greater than 4, then there exists a rational subspace U of codimension 1 such that $(Q|_U, L|_U)$ satisfies the same conditions. Moreover, U can be chosen such that $(Q|_U, L|_U)$ is of type (I).*

Consider the set $\Omega = \{(\ell_1, \ell_2, \ell_3)\} \subset \mathbb{R}^{3d}$ of triples of linear forms of dimension d defined by the following conditions:

- (1) ℓ_1, ℓ_2, ℓ_3 are linearly independent.
- (2) $L \neq 0$ on the space $\{\ell_i = 0 : i = 1, 2, 3\}$.
- (3) Q is nondegenerate on the space $\{\ell = 0 : \ell \in T\}$ for any subset $T \subseteq \{\ell_1, \ell_2, \ell_3\}$.
- (4) $(Q|_{\ell_i=0}, L|_{\ell_i=0})$ is of type (I) for $i = 1, 2, 3$.
- (5) $Q|_{\{\ell_i=0\} \cap \{L=0\}}$ is indefinite for $i = 1, 2, 3$.

Lemma 5. *The set Ω is nonempty and open.*

Proof. Let Ω_0 be the set of triples of linear forms that satisfy conditions (1) and (2), and Ω_j the set of triples in Ω_0 that satisfy condition (j), $j = 3, 4, 5$. Note that the set Ω_0 is the complement of a proper algebraic set (i.e. a set defined by polynomial equations).

The sets Ω_j , $j = 3, 4, 5$, are not empty. This is easy to see using the canonical forms from Proposition 2. For example, when (Q, L) is the canonical form (II), $(\ell_1, \ell_2, \ell_3) \in \Omega_4$ for $\ell_i(\bar{x}) = x_{d-4-i} + x_{d-1} + x_d$, $i = 1, 2, 3$. It is also clear that the sets Ω_j , $j = 3, 4, 5$, are open. To show this for Ω_4 , we use that a pair (Q, L) is of type (I) iff

$$\det(Q) \neq 0, \det(Q|_{L=0}) \neq 0, L \neq 0.$$

It suffices to show that Ω_3 and Ω_4 are dense. Indeed, it then follows that $\Omega_3 \cap \Omega_4$ is an open dense set, and $\Omega = \Omega_3 \cap \Omega_4 \cap \Omega_5$ is nonempty and open.

We claim that for every $T \subseteq \{\ell_1, \ell_2, \ell_3\}$, the set of triples $(\ell_1, \ell_2, \ell_3) \in \Omega_0$ such that Q is nondegenerate on the space $\{\ell = 0 : \ell \in T\}$ contains the complement of a proper algebraic subset. This will imply that the set Ω_3 is dense. To simplify notations, we only consider the case of one linear form. Namely, we show that the set of nonzero linear forms ℓ such that $Q|_{\ell=0}$ is nondegenerate contains the complement of a proper algebraic subset. The cases of pairs and triples are handled similarly. For a nonzero linear form ℓ , there exists a basis $\{v_i^\ell : i = 1, \dots, d - 1\}$ of the space $\{\ell = 0\}$ such that the coordinates of the vectors v_i^ℓ are rational functions of the coefficients of ℓ . Define a rational function

$$\phi(\ell) \stackrel{def}{=} \det(Q(v_i^\ell, v_j^\ell) : i, j = 1, \dots, d - 1).$$

For a linear form ℓ such that $\phi(\ell)$ is defined, $Q|_{\ell=0}$ is nondegenerate iff $\phi(\ell) \neq 0$. If $\phi = 0$ on its domain, $Q|_{\ell=0}$ is nondegenerate only for ℓ in a proper algebraic subset where ϕ is undefined. This is a contradiction because Ω_3 is nonempty and open.

Hence, $\phi \neq 0$. The form $Q|_{\ell=0}$ is nondegenerate for $\ell \in \{\ell : \phi(\ell) \neq 0\}$. This set is the complement of a proper algebraic set.

To prove that Ω_4 is dense, we show that the set of nonzero linear forms ℓ such that $(Q|_{\ell=0}, L|_{\ell=0})$ is of type (I) contains the complement of a proper algebraic subset. The form $(Q|_{\ell=0}, L|_{\ell=0})$ is of type (I) iff

$$\det(Q|_{\ell=0}) \neq 0, \det(Q|_{\{L=0, \ell=0\}}) \neq 0, L|_{\ell=0} \neq 0.$$

Note that the first inequality and the third inequality define sets that contain the complements of proper algebraic subsets. Hence, it is enough to prove that the set of linear forms ℓ that satisfy the second inequality contains the complement of a proper algebraic subset. There exists a basis $\{w_i^\ell : i = 1, \dots, d - 2\}$ of the space $\{L = 0, \ell = 0\}$ such that the coordinates of the basis vectors are rational functions of the coefficients of ℓ . Define a rational function

$$\psi(\ell) \stackrel{def}{=} \det(Q(w_i^\ell, w_j^\ell) : i, j = 1, \dots, d - 2).$$

For ℓ such that $\psi(\ell)$ is defined, $Q|_{\{L=0, \ell=0\}}$ is nondegenerate iff $\psi(\ell) \neq 0$. Therefore, we deduce as above that the set of ℓ such that $Q|_{\{L=0, \ell=0\}}$ is nondegenerate contains the complement of a proper algebraic subset. This implies that Ω_4 is dense and proves the lemma. \square

Denote by $\pi : \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d \rightarrow \mathbb{R}^d \times \mathbb{R}^d$ the projection on the first two coordinates, and by $p : \mathbb{R}^d \times \mathbb{R}^d \times \mathbb{R}^d \rightarrow \mathbb{R}^d$ the projection on the first coordinate.

Lemma 6. *Suppose that $(l_1, m_1), (l_2, m_2), (m_1, m_2) \in \pi(\Omega)$. Then there exists a rational linear form n such that*

$$(l_1, m_1, n), (l_2, m_2, n), (m_1, m_2, n) \in \Omega.$$

Proof. As in the previous lemma, one shows that if $(l, m) \in \pi(\Omega)$, the set of n such that (l, m, n) satisfies conditions (1)–(4) is open and dense. Thus, the set of linear forms n such that the triples (l_1, m_1, n) , (l_2, m_2, n) , and (m_1, m_2, n) satisfy conditions (1)–(4) is open and dense. The condition that $Q|_{\{n=0\} \cap \{L=0\}}$ is indefinite holds on an open set of n . Hence, such a linear form n exists. \square

For a linear form ℓ , consider a linear map F_ℓ from the space of quadratic forms on \mathbb{R}^d to the space of quadratic forms on $\{\ell = 0\}$ defined by

$$F_\ell(Q) = Q|_{\ell=0}.$$

This map is rational if ℓ is rational. The kernel of F_ℓ is

$$\langle x_i \ell : i = 1, \dots, d \rangle.$$

Proof of Proposition 4. Suppose that for any rational linear form l from $p(\Omega)$, the quadratic form $(\alpha Q + \beta L^2)|_{l=0}$ is rational for some α and β with $(\alpha, \beta) \neq 0$. This means that $F_l(\langle Q, L^2 \rangle)$ has a rational subspace of codimension 1, or, equivalently, for some $\alpha, \beta \in \mathbb{R}$ such that $(\alpha, \beta) \neq 0$, the space $\langle \alpha Q + \beta L^2, x_i l : i = 1, \dots, d \rangle$ is rational.

Case 1. For any rational linear forms l and m such that $(l, m) \in \pi(\Omega)$, the space $\langle Q, L^2, x_i l, x_j m : i, j = 1, \dots, d \rangle$ is rational.

We will use the following claim:

Claim. Let S not be in $\langle Q, L^2 \rangle$. Then there are rational linear forms l and m such that $(l, m) \in \pi(\Omega)$, and S is not in

$$\langle Q, L^2, x_{il}, x_{jm} : i, j = 1, \dots, d \rangle.$$

Proof. Suppose not. Then for any rational linear forms l and m such that $(l, m) \in \pi(\Omega)$, we have $S = \alpha(l, m)Q + \beta(l, m)L^2$ on the subspace $\{l = 0\} \cap \{m = 0\}$ for some $\alpha(l, m), \beta(l, m) \in \mathbb{R}$. First, we show that $\alpha(l, m)$ and $\beta(l, m)$ are independent of (l, m) on a large set of pairs. Let $(l, m, n) \in \Omega$ for some rational linear forms l, m, n . Because of condition (3), Q has rank at least 2 on the space

$$V \stackrel{def}{=} \{l = 0\} \cap \{m = 0\} \cap \{n = 0\}.$$

Therefore, $Q|_V$ and $L^2|_V$ are linearly independent. It follows that

$$(1) \quad \alpha(l, m) = \alpha(m, n) = \alpha(n, l) \quad \text{and} \quad \beta(l, m) = \beta(m, n) = \beta(n, l).$$

Fix $(l_0, m_0) \in \pi(\Omega)$ with rational linear forms l_0 and m_0 . Consider the set

$$\mathcal{O} = \{(l, m) \in \pi(\Omega) : (m, m_0) \in \pi(\Omega)\}.$$

This is a nonempty open set in $\pi(\Omega)$. By Lemma 6, there is a rational linear form n such that $(l_0, m_0, n), (l, m, n), (m, m_0, n) \in \Omega$. Then using (1), we obtain

$$\alpha(l_0, m_0) = \alpha(m_0, n) = \alpha(m, n) = \alpha(l, m),$$

and similarly, $\beta(l_0, m_0) = \beta(l, m)$. Hence, the coefficients $\alpha(l, m)$ and $\beta(l, m)$ are constant for rational linear forms l and m such that $(l, m) \in \mathcal{O}$. Thus, $S - \alpha Q - \beta L^2 = 0$ on the space $\{l = 0\} \cap \{m = 0\}$ for rational linear forms l and m such that $(l, m) \in \mathcal{O}$. It follows that $S - \alpha Q - \beta L^2 = 0$ on an open subset of \mathbb{R}^d . Hence, $S = \alpha Q + \beta L^2$. This is a contradiction. \square

Using the claim, we conclude that the space $\langle Q, L^2 \rangle$ is an intersection of spaces of the form $\langle Q, L^2, x_{il}, x_{jm} : i, j = 1, \dots, n \rangle$ for some rational linear forms l and m such that $(l, m) \in \mathcal{O}$. By the assumption of Case 1, each of these spaces is rational. Hence, the space $\langle Q, L^2 \rangle$ is rational, too. This gives a contradiction.

Case 2. For some rational linear forms l and m such that $(l, m) \in \pi(\Omega)$, the space $\langle Q, L^2, x_{il}, x_{jm} : i, j = 1, \dots, d \rangle$ is not rational.

By the assumption, the space $\langle \alpha Q + \beta L^2, x_{il} : i = 1, \dots, d \rangle$ is rational for some $\alpha, \beta \in \mathbb{R}$ such that $(\alpha, \beta) \neq 0$. Then the space

$$\langle \alpha Q + \beta L^2, x_{il}, x_{jm} : i, j = 1, \dots, d \rangle$$

is rational, too. It follows from the assumption of Case 2 that the pair (α, β) with this property is uniquely defined up to a scalar multiple. Let $\tilde{Q} = \alpha Q + \beta L^2$. We show that \tilde{Q} is proportional to a rational form. The pair (α, β) can be chosen such that the form $\tilde{Q}|_{l=0}$ is rational.

Because of the uniqueness of (α, β) , $\tilde{Q}|_{k=0}$ is proportional to a rational form for any rational linear form $k \in p(\Omega) \cap \langle l, m \rangle$. Note that the latter set is not empty because l and m is in it. Let $\{e_i : i = 1, \dots, d - 2\}$ be a rational basis of $\{l = 0\} \cap \{m = 0\}$. We complete it to a rational basis of \mathbb{R}^d by vector e_{d-1} and e_d such that $l(e_{d-1}) = 0$. Let

$$U_t = \langle e_i, e_{d-1} + te_d : i = 1, \dots, d - 2 \rangle \quad \text{for } t \in \mathbb{Q}.$$

Since $U_0 = \{l = 0\}$ and $l \in p(\Omega)$, a rational form k_t that defines U_t is in $p(\Omega)$ for sufficiently small t . Also $k_t \in \langle l, m \rangle$ because

$$\{l = 0\} \cap \{m = 0\} \subseteq U_t.$$

Therefore, $\alpha_t \tilde{Q}|_{U_t}$ is rational for some $\alpha_t \neq 0$ when t is rational and sufficiently small. Since $(l, m) \in \pi(\Omega)$, $\tilde{Q} \neq 0$ on the space $\{l = 0\} \cap \{m = 0\}$. Take a rational vector $x \in \{l = 0\} \cap \{m = 0\}$ such that $\tilde{Q}(x) \neq 0$. Then $\tilde{Q}(x) \in \mathbb{Q}$, and $\alpha_t \tilde{Q}(x) \in \mathbb{Q}$. Therefore, $\alpha_t \in \mathbb{Q}$, and $\tilde{Q}|_{U_t}$ is rational for sufficiently small t . In particular, when $t = 0$, $\tilde{Q}(e_i, e_j) \in \mathbb{Q}$ for $i, j < d$. Also

$$\tilde{Q}(e_i, e_{d-1} + te_d) = \tilde{Q}(e_i, e_{d-1}) + t\tilde{Q}(e_i, e_d) \in \mathbb{Q},$$

so that $\tilde{Q}(e_i, e_d) \in \mathbb{Q}$ for $i < d$. Finally,

$$\tilde{Q}(e_{d-1} + te_d) = \tilde{Q}(e_{d-1}) + 2t\tilde{Q}(e_{d-1}, e_d) + t^2\tilde{Q}(e_d) \in \mathbb{Q}.$$

Thus, $\tilde{Q}(e_d) \in \mathbb{Q}$. This shows that \tilde{Q} is rational which is a contradiction. □

4. PAIRS OF TYPE (I)

In this section we consider a pair (Q, L) of type (I) and dimension 4. By Proposition 2, the pair (Q, L) is equivalent to either

$$(x_1^2 + x_2^2 - x_3^2 - x_4^2, x_4) \text{ or } (x_1^2 - x_2^2 - x_3^2 - x_4^2, x_4).$$

We consider the first case. The other case can be done the same way. Let

$$(2) \quad Q_0 = x_1^2 + x_2^2 - x_3^2 - x_4^2 \quad \text{and} \quad L_0 = x_4.$$

Let

$$(3) \quad H = \left(\begin{array}{c|c} \text{SO}(2,1) & 0 \\ \hline 0 & 1 \end{array} \right) \subseteq \text{SL}(4, \mathbb{C}).$$

Note that the group H leaves the pair (Q_0, L_0) invariant.

First, we collect some simple facts.

Proposition 7. *Let F be a connected semisimple algebraic subgroup of $SL(4, \mathbb{C})$ which acts irreducibly on \mathbb{C}^4 such that*

$$H \subsetneq F \subsetneq SL(4, \mathbb{C}).$$

Then $G = SO(S, \mathbb{C})$ for some nondegenerate quadratic form S .

Proof. Let \mathfrak{f} be the Lie algebra of F . For convenience of the reader, let us reproduce in Table 1 the list of complex semisimple Lie algebras of dimension up to 14 and dimensions of their faithful irreducible representations (see [OV]). Note that an irreducible representation of a semisimple algebra is a tensor product of irreducible representations of simple factors.

One can see that \mathfrak{f} should be of type $A_1 + A_1$ or C_2 . The 4-dimensional irreducible representation of the algebra of type C_2 is symplectic. On the other hand, $H \subset F$ acts irreducibly on a 3-dimensional subspace, and leaves invariant a nonzero symmetric form on this subspace. This shows that F cannot leave a nonzero symplectic form invariant. Thus, \mathfrak{f} is of type $A_1 + A_1$. Since \mathfrak{f} has a unique irreducible 4-dimensional representation, this representation is equivalent to the representation of $\mathfrak{so}(4, \mathbb{C})$ on \mathbb{C}^4 . This means that $\mathfrak{f} = g\mathfrak{so}(4, \mathbb{C})g^{-1}$ for some $g \in \text{SL}(4, \mathbb{C})$. Equivalently, $\mathfrak{f} = \mathfrak{so}(S, \mathbb{C})$ for some nondegenerate quadratic form S . Since F is connected, $F = \text{SO}(S, \mathbb{C})$. □

TABLE 1. Complex irreducible representations

\mathfrak{g}	$\dim \mathfrak{g}$	$\dim \rho$
A_1	3	2, 3, 4, ...
$A_1 + A_1$	6	4, ...
$A_1 + A_1 + A_1$	9	8, ...
$A_1 + A_1 + A_1 + A_1$	12	16, ...
A_2	8	3, 8, ...
$A_2 + A_1$	11	6, ...
$A_2 + A_1 + A_1$	14	12, ...
$B_2 = C_2$	10	4, 5, ...
$B_2 + A_1$	13	8, ...
G_2	14	7, ...

Lemma 8. *Let $G \subseteq GL(d, \mathbb{C})$ be an algebraic group that acts irreducibly on \mathbb{C}^d . Then its unipotent radical is trivial.*

Proof. Let U be the unipotent radical of G , and $V = \mathbb{C}^d$. Consider the space

$$V^U = \{x \in V : Ux = x\}.$$

Since U is unipotent, $V^U \neq 0$. Since U is normal in G , V^U is G -invariant. Thus, $V^U = V$, and $U = 1$. □

Lemma 9. *Let Q be a quadratic form on \mathbb{C}^4 which is invariant under the action of H (H is defined in (3)). Then $Q = \alpha Q_0 + \beta L_0^2$ for some $\alpha, \beta \in \mathbb{C}$, where Q_0 and L_0 are defined in (2).*

Proof. Let us write $Q = Q(x_1, x_2, x_3, 0) + L(x_1, x_2, x_3)x_4 + \beta x_4^2$ for some linear form L and $\beta \in \mathbb{C}$. Then $Q(\cdot, \cdot, \cdot, 0)$ and L is $SO(2, 1)$ -invariant. It follows that $Q(\cdot, \cdot, \cdot, 0) = \alpha Q_0(\cdot, \cdot, \cdot, 0)$ for some $\alpha \in \mathbb{C}$ and $L = 0$. □

The following proposition is the main result of this section and a partial case of Theorem 1.

Proposition 10. *Let Q be a nondegenerate quadratic form, and let L be a linear form such that $(Q(x), L(x)) = (\lambda Q_0(gx), \mu L_0(gx))$ for some $g \in SL(4, \mathbb{R})$ and $\lambda, \mu \in \mathbb{R} - \{0\}$, where Q_0 and L_0 are defined in (2). Suppose that for every $(\alpha, \beta) \neq (0, 0)$, with $\alpha, \beta \in \mathbb{R}$, the linear combination $\alpha Q + \beta L^2$ is not rational. Then $\{(Q(x), L(x)) : x \in \mathcal{P}(\mathbb{Z}^4)\}$ is dense in \mathbb{R}^2 .*

Proof. Without loss of generality, $\lambda = \mu = 1$. Let $G = SL(4, \mathbb{C})$ and H be as in (3). We study the action of $H_{\mathbb{R}}$ on $G_{\mathbb{R}}/G_{\mathbb{Z}}$. By Ratner’s Theorem [Ra91], the closure $\overline{H_{\mathbb{R}}gG_{\mathbb{Z}}} \subseteq G_{\mathbb{R}}/G_{\mathbb{Z}}$ is a homogeneous space. Moreover by the result of Shah [Sh91, Proposition 3.2], $\overline{H_{\mathbb{R}}gG_{\mathbb{Z}}} = gF_{\mathbb{R}}^oG_{\mathbb{Z}}$, where F is the smallest algebraic \mathbb{Q} -subgroup containing $g^{-1}Hg$, and the radical of F is unipotent. Here $F_{\mathbb{R}}^o$ denotes the connected component of $F_{\mathbb{R}}$ with respect to the Euclidean topology. Since H is connected as an algebraic group, F is connected, too.

First, we consider the case when F acts irreducibly on \mathbb{C}^4 . By Lemma 8, F is semisimple, and by Proposition 7, F is one of the subgroups $g^{-1}Hg$, G , $SO(S, \mathbb{C})$ for some nondegenerate quadratic form S . Since F acts irreducibly on \mathbb{C}^4 , $F \neq g^{-1}Hg$. Suppose that $F = SO(S)$. Since F is defined over \mathbb{Q} , the quadratic form

S is proportional to a rational form (see, for example, [Bo95]). By Lemma 9, $S = \alpha Q + \beta L^2$ for some $\alpha, \beta \in \mathbb{C}$. This is a contradiction. Thus, $F = G$. We conclude that $\overline{H_{\mathbb{R}}gG_{\mathbb{Z}}} = G_{\mathbb{R}}/G_{\mathbb{Z}}$. Then

$$\begin{aligned} & \overline{\{(Q(x), L(x)) : x \in \mathcal{P}(\mathbb{Z}^4)\}} \\ &= \overline{\{(Q_0(hg\gamma e_1), L_0(hg\gamma e_1)) : h \in H_{\mathbb{R}}, \gamma \in G_{\mathbb{Z}}\}} \\ &= \{(Q_0(ae_1), L_0(ae_1)) : a \in G_{\mathbb{R}}\} = \{(Q_0(x), L_0(x)) : x \in \mathbb{R}^4\} = \mathbb{R}^2. \end{aligned}$$

Here $e_1 = (1, 0, \dots, 0)$, and the last equality holds by Lemma 3.

Now we assume that the action of F on \mathbb{C}^4 is not irreducible. Then the action of F on the dual space \mathcal{L} is reducible, too. The dual action of H has irreducible components $\langle x_1, x_2, x_3 \rangle$ and $\langle x_4 \rangle$. Moreover, for any linear form $l \notin \langle x_4 \rangle$, the smallest H -invariant subspace containing l should contain $\langle x_1, x_2, x_3 \rangle$. Therefore, $\langle x_1, x_2, x_3 \rangle$ and $\langle x_4 \rangle$ are the only nontrivial H -invariant subspaces. For $i = 1, \dots, 4$, define linear forms $\ell_i(x) = (gx)_i$. Then

$$Q = \ell_1^2 + \ell_2^2 - \ell_3^2 - \ell_4^2 \quad \text{and} \quad L = \ell_4.$$

It follows that $\mathcal{L}_1 \stackrel{\text{def}}{=} \langle \ell_1, \ell_2, \ell_3 \rangle$ and $\mathcal{L}_2 \stackrel{\text{def}}{=} \langle \ell_4 \rangle$ are the only candidates for nontrivial F -invariant subspaces. Let F be semisimple. Then its action is completely reducible. Therefore, \mathcal{L}_1 and \mathcal{L}_2 are F -invariant, and since F has no nontrivial characters, the space of F -fixed vectors $\mathcal{L}^F = \mathcal{L}_2 = \langle L \rangle$. Using that F is a \mathbb{Q} -group, we conclude that $\langle L \rangle$ is a \mathbb{Q} -subspace. This means that L is proportional to a rational form, which is a contradiction. Therefore, F is not semisimple, and its unipotent radical $U \neq 1$. Note that U is defined over \mathbb{Q} . The subspace of U -fixed vectors \mathcal{L}^U is F -invariant, so that either $\mathcal{L}^U = \mathcal{L}_1$ or $\mathcal{L}^U = \mathcal{L}_2 = \langle L \rangle$. If the latter holds, L is proportional to a rational form by the same argument as above. Thus, we may assume that $\mathcal{L}^U = \mathcal{L}_1$. In particular, \mathcal{L}_1 is a \mathbb{Q} -subspace. Since F is defined over \mathbb{Q} , it has a Levi subgroup F_0 which is defined over \mathbb{Q} . It follows from the description of F -invariant subspaces that F_0 acts irreducibly on \mathcal{L}^U . There exists an F_0 -invariant complement for \mathcal{L}^U generated by a linear form ℓ_0 . We have that $\mathcal{L}^{F_0} = \langle \ell_0 \rangle$. In particular, $\langle \ell_0 \rangle$ is a \mathbb{Q} -subspace, and the linear form ℓ_0 can be chosen to be rational. By Malcev’s theorem, $g^{-1}Hg \subseteq u^{-1}F_0u$ for some $u \in U$. The forms $L(u^{-1} \cdot x)$ and $\ell_0(x)$ are both fixed by F_0 , so that $L(u^{-1} \cdot x) = \alpha \cdot \ell_0(x)$ for some $\alpha \in \mathbb{R} - \{0\}$.

Suppose that $g^{-1}Hg = u^{-1}F_0u$. Then F_0 stabilizes the pair

$$(Q(u^{-1} \cdot x), L(u^{-1} \cdot x)) = (\ell_1^2 + \ell_2^2 - \ell_3^2 - \alpha^2 \ell_0^2, \alpha \ell_0).$$

Since F_0 is a \mathbb{Q} -group, the space of quadratic forms that are fixed by F_0 is a \mathbb{Q} -space. By Lemma 9, this space is spanned by $\ell_1^2 + \ell_2^2 - \ell_3^2 - \alpha^2 \ell_0^2$ and ℓ_0^2 . Therefore, for some $\alpha, \beta \in \mathbb{R}$, the form

$$\tilde{Q} \stackrel{\text{def}}{=} \alpha(\ell_1^2 + \ell_2^2 - \ell_3^2) + \beta \ell_0^2$$

is rational. Since the space $\mathcal{L}_1 = \langle \ell_1, \ell_2, \ell_3 \rangle$ is rational, there exists a rational vector $x_0 \neq 0$ such that $\ell_1(x_0) = \ell_2(x_0) = \ell_3(x_0) = 0$. Clearly, $\ell_0(x_0) \neq 0$. Then $\tilde{Q}(x_0) = \beta \cdot \ell_0(x_0)^2 \in \mathbb{Q}$. Therefore, $\beta \in \mathbb{Q}$, and the form $Q + L^2 = \ell_1^2 + \ell_2^2 - \ell_3^2$ is proportional to a rational form, which is a contradiction.

Now we may assume that $g^{-1}Hg \subsetneq u^{-1}F_0u$. Then

$$F_0 = ug^{-1} \left(\begin{array}{c|c} \text{SL}(3) & 0 \\ \hline 0 & 1 \end{array} \right) gu^{-1}.$$

Also

$$F_1 \stackrel{def}{=} g^{-1} \left(\frac{\text{SL}(3) \mid 0}{0 \mid 1} \right) g \subseteq F.$$

An element $u \in U$ acts on \mathcal{L} as follows: $u \cdot \ell = \ell$ for $\ell \in \mathcal{L}_1$, and $u \cdot \ell_4 = \ell_4 + \ell_u$ for some linear form $\ell_u \in \mathcal{L}_1$. Then the adjoint action of F_1 on U corresponds to the usual action of F_1 on the space spanned by linear forms ℓ_u , $u \in U$. It follows that for every $\ell \in \mathcal{L}_1$, there exists $u \in U$ such that $u \cdot \ell_4 = \ell_4 + \ell$.

Let $\{e_i : i = 1, \dots, 4\}$ be the standard basis of \mathbb{C}^4 . Fix $(a, b) \in \mathbb{R}^2$. Take $x \in \mathcal{P}(\mathbb{Z}^4) - \langle g^{-1}e_4 \rangle$. By the previous remark, there exists $u \in U_{\mathbb{R}}$ such that

$$L(ux) = (u \cdot \ell_4)(x) = b.$$

Write $ux = x_1 + x_2$ for $x_1 \in g^{-1} \langle e_1, e_2, e_3 \rangle$ and $x_2 \in g^{-1} \langle e_4 \rangle$. Since Q is indefinite on the subspace $g^{-1} \langle e_1, e_2, e_3 \rangle$, there exists $f \in F_1$ such that $Q(fx_1) = a - Q(x_2)$. Then

$$Q(fux) = Q(fx_1) + Q(x_2) = a.$$

Since

$$\overline{g^{-1}H_{\mathbb{R}}gG_{\mathbb{Z}}} = F_{\mathbb{R}}^{\circ}G_{\mathbb{Z}} = F_{1\mathbb{R}}U_{\mathbb{R}}G_{\mathbb{Z}},$$

there exist $h_n \in g^{-1}H_{\mathbb{R}}g$ and $\gamma_n \in G_{\mathbb{Z}}$ such that $h_n\gamma_n \rightarrow fu$ as $n \rightarrow \infty$. Finally,

$$\begin{aligned} (Q(\gamma_n x), L(\gamma_n x)) &= (Q(h_n \gamma_n x), L(h_n \gamma_n x)) \\ &\rightarrow (Q(fux), L(fux)) = (a, b). \end{aligned}$$

The proposition is proved. □

Remark 11. Proposition 10 combined with Proposition 4 implies Theorem 1 for dimension $d \geq 5$.

5. PAIRS OF TYPE (II)

Now we prove Theorem 1 for pairs of type (II) of dimension 4. This will finish the proof of Theorem 1. Let

$$(4) \quad Q_0 = x_1x_4 - x_2x_3 \quad \text{and} \quad L_0 = x_4.$$

Note that we use a different (cf. Proposition 2) canonical form to simplify calculations.

Let

$$(5) \quad H = \left\{ \left(\begin{array}{cccc} 1 & a & b & ab \\ 0 & 1 & 0 & b \\ 0 & 0 & 1 & a \\ 0 & 0 & 0 & 1 \end{array} \right) : a, b \in \mathbb{C} \right\} \subseteq \text{SL}(4, \mathbb{C}).$$

It is easy to check that $Q_0(hx) = Q_0(x)$ and $L_0(hx) = L_0(x)$ for $h \in H$.

Lemma 12. *The only nontrivial H-invariant subspaces of the dual action of H (i.e. the action on the space \mathcal{L} of linear forms) are*

- $\langle x_4 \rangle$,
- $\langle \alpha x_2 + \beta x_3, x_4 \rangle$ for some $\alpha, \beta \in \mathbb{C}$,
- $\langle x_2, x_3, x_4 \rangle$.

Proof. One can check that x_4 is the only fixed vector of H (up to a scalar multiple). Since the action of H is unipotent, every nontrivial H -invariant subspace \mathcal{V} contains a nonzero vector fixed by H . It follows that $\langle x_4 \rangle \subseteq \mathcal{V}$. Consider a factor space $\mathcal{L}/\langle x_4 \rangle$. The subspace $\langle x_2, x_3, x_4 \rangle / \langle x_4 \rangle$ consists of H -fixed vectors, and for any $v \notin \langle x_2, x_3, x_4 \rangle$, one has $\langle Hv, x_4 \rangle = \mathcal{L}$. The conclusion follows. \square

Lemma 13. (1) *Let G be a simple group, and $\bar{G} = G \times G$. Denote by π_1 and π_2 the projection maps. Let $H \not\leq \bar{G}$ be such that $\pi_i(H) = G$ for $i = 1, 2$. Then $H = \{(\alpha(g), g) : g \in G\}$ for some automorphism α of G .*
 (2) *Let $\mathfrak{g} = \mathfrak{sl}(2, \mathbb{C})$, and $\bar{\mathfrak{g}} = \mathfrak{g} \oplus \mathfrak{g}$. Denote by π_1 and π_2 the projection maps. Let $\mathfrak{h} \not\leq \bar{\mathfrak{g}}$ be such that $\pi_i(\mathfrak{h}) = \mathfrak{g}$ for $i = 1, 2$. Then $\mathfrak{h} = \{(Ad(g)x, x) : x \in \mathfrak{g}\}$ for some $g \in SL(2, \mathbb{C})$.*

Proof. Let

$$S_1 = \{g \in G : (g, e) \in H\} \text{ and } S_2 = \{g \in G : (e, g) \in H\}.$$

It is easy to check that S_1 and S_2 are normal subgroups of G , that is, $g^{-1}S_i g \subseteq S_i$ for every $g \in G, i = 1, 2$. Since G is simple, S_i is either $\{e\}$ or G .

Suppose that $S_1 = G$. We show that $H = \bar{G}$. Let $(g, h) \in \bar{G}$. For some $g_1 \in G, (g_1, h) \in H$. Then

$$(g, h) = (g_1, h)(g_1^{-1}g, e) \in H.$$

Hence, $H = \bar{G}$. Similarly, $H = \bar{G}$ if $S_2 = G$.

Suppose that $S_1 = S_2 = \{e\}$. For any $g \in G$, there exists a unique element $\alpha(g)$ such that $(\alpha(g), g) \in H$. Because of the uniqueness, α is a homomorphism. It is surjective because $\pi_1(H) = G$ and injective because $S_2 = \{e\}$. This proves the first part of the lemma.

It is straightforward to rewrite this argument for simple Lie algebras. It is known that any automorphism of $\mathfrak{sl}(2, \mathbb{C})$ is inner. Thus, the second part of the lemma follows. \square

The following proposition finishes the proof of Theorem 1. Its proof is similar to the proof of Proposition 10.

Proposition 14. *Let Q be a nondegenerate quadratic form, and let L be a linear form such that $(Q(x), L(x)) = (\lambda Q_0(gx), \mu L_0(gx))$ for some $g \in SL(4, \mathbb{R})$ and $\lambda, \mu \in \mathbb{R} - \{0\}$, where Q_0 and L_0 are defined in (4). Suppose that for every $(\alpha, \beta) \neq (0, 0)$, with $\alpha, \beta \in \mathbb{R}$, the linear combination $\alpha Q + \beta L^2$ is not rational. Then $\{(Q(x), L(x)) : x \in \mathcal{P}(\mathbb{Z}^4)\}$ is dense in \mathbb{R}^2 .*

Proof. We may assume that $\lambda = \mu = 1$. Let $G = SL(4, \mathbb{C})$, and H be as in (5). Consider the action of $H_{\mathbb{R}}$ on $G_{\mathbb{R}}/G_{\mathbb{Z}}$. As in the proof of Proposition 10, we know that $\overline{H_{\mathbb{R}}gG_{\mathbb{Z}}} = gF_{\mathbb{R}}^oG_{\mathbb{Z}}$, where F is the smallest algebraic \mathbb{Q} -subgroup containing $g^{-1}Hg$. The group F is connected as an algebraic group, and its radical is unipotent. There is Levi decomposition $F = F_0U$, where F_0 is a connected (as an algebraic group) semisimple \mathbb{Q} -subgroup, and U is the unipotent radical of F . Note that U is defined over \mathbb{Q} .

To prove the proposition, it is enough to show that

$$(6) \quad \overline{\{(Q(fz), L(fz)) : f \in F_{\mathbb{R}}^o, z \in \mathcal{P}(\mathbb{Z}^4)\}} = \mathbb{R}^2.$$

Consider the action of F on the space of linear forms \mathcal{L} . Let \mathcal{V} be a nontrivial F -invariant subspace. Since H is unipotent, \mathcal{V} contains a nonzero vector fixed

by $g^{-1}Hg$. By Lemma 12, the only vector fixed by $g^{-1}Hg$ is L (up to a scalar multiple). Thus, $\langle L \rangle \subseteq \mathcal{V}$. It follows that there is a unique F -irreducible subspace $\mathcal{V} \subseteq \mathcal{L}$. Namely, it is the intersection of all nontrivial F -invariant subspaces. This subspace is contained in every F -invariant subspace. Also \mathcal{V} is defined over \mathbb{Q} . Indeed, for any $\sigma \in \text{Gal}(\mathbb{C}/\mathbb{Q})$, \mathcal{V}^σ is $F(\mathbb{Q})$ -invariant, and $F(\mathbb{Q})$ is Zariski dense in F because F is connected. Therefore, \mathcal{V}^σ is F -invariant, and $\mathcal{V} \subseteq \mathcal{V}^\sigma$. Comparing dimensions, we conclude that $\mathcal{V} = \mathcal{V}^\sigma$. This shows that \mathcal{V} is defined over \mathbb{Q} .

Let \mathcal{L}^U be the subspace of vectors fixed by U . Since U is normal in F , the space \mathcal{L}^U is F -invariant, so that $\mathcal{V} \subseteq \mathcal{L}^U$. It follows that F_0 act irreducibly on \mathcal{V} . Since F_0 is semisimple, the F -action on \mathcal{L}^U is completely reducible. Suppose that $\mathcal{V} \subsetneq \mathcal{L}^U$. Then $\mathcal{L}^U = \mathcal{V} \oplus \mathcal{W}$ for some F -invariant subspace \mathcal{W} . However, this contradicts the description of H -invariant subspaces in Lemma 12. Thus, $\mathcal{V} = \mathcal{L}^U$.

We can write

$$\mathcal{L}_{\mathbb{R}} = \mathcal{V}_{\mathbb{R}} \oplus \mathcal{W}_{\mathbb{R}}$$

for some real $(F_0)_{\mathbb{R}}$ -invariant subspace $\mathcal{W}_{\mathbb{R}}$. Then $\mathcal{L} = \mathcal{V} \oplus \mathcal{W}$, where $\mathcal{W} = \mathcal{W}_{\mathbb{R}} \otimes \mathbb{C}$ is F_0 -invariant because $(F_0)_{\mathbb{R}}$ is Zariski dense in F_0 . Note that \mathcal{W} is defined over \mathbb{R} . Let

$$V = \{v \in \mathbb{C}^4 : \ell(v) = 0 \text{ for } \ell \in \mathcal{V}\}$$

and

$$W = \{v \in \mathbb{C}^4 : \ell(v) = 0 \text{ for } \ell \in \mathcal{W}\}.$$

Clearly, $\mathbb{C}^4 = V \oplus W$, V is F -invariant, and W is F_0 -invariant. Moreover, W is F_0 -irreducible because $W \simeq \mathbb{C}^4/V$ as F_0 -modules, and any nontrivial F_0 -invariant subspace of \mathbb{C}^4/V would give by duality a nontrivial F_0 -invariant subspace in \mathcal{V} . The space $(\mathbb{C}^4/V)^U$ is nonzero and F_0 -invariant. It follows that $(\mathbb{C}^4/V)^U = \mathbb{C}^4/V$, so that U acts trivially on \mathbb{C}^4/V .

Let $\ell_i(x) = (gx)_i$ for $i = 1, \dots, 4$. Then $Q = \ell_1\ell_4 - \ell_2\ell_3$ and $L = \ell_4$.

Consider several cases:

Case 1. $\dim \mathcal{V} = 1$. Then $\mathcal{V} = \langle L \rangle$, and since \mathcal{V} is defined over \mathbb{Q} , L is a multiple of a rational form. This is a contradiction.

Case 2. $\dim \mathcal{V} = 2$. Then $\dim V = \dim W = 2$. Since F_0 is semisimple, the action of F_0 on V is either trivial or irreducible.

Denote

$$A = \{g \in \text{SL}(4, \mathbb{C}) : g|_V = id, g|_W = id + a \text{ for } a \in \text{End}(W, V)\}.$$

Suppose that F_0 acts irreducibly on V . Then U acts trivially on V because otherwise $V^U \neq 0$ is a nontrivial F_0 -invariant subspace. Since it was shown above that U acts trivially on \mathbb{C}^4/V , too, this implies that $U \subseteq A$. The Lie algebra $\mathfrak{f}_0 \subseteq \mathfrak{sl}(V) \times \mathfrak{sl}(W)$ of F_0 satisfies the conditions of Lemma 13 unless $\mathfrak{f}_0 = \mathfrak{sl}(V) \times \mathfrak{sl}(W)$.

First, we consider the case when the last equality holds. Then A is an irreducible F_0 -module. Suppose that $U = 1$. Then \mathcal{V} and \mathcal{W} are F -invariant subspaces such that $\mathcal{V} + \mathcal{W} = \mathcal{L}$. Since every two 2-dimensional subspaces in Lemma 12 are contained in the unique 3-dimensional subspace, this gives a contradiction. Thus, $U \neq 1$, and since it is a submodule of the irreducible F_0 -module A , we conclude that $U = A$. In particular, for any $x \notin V_{\mathbb{R}}$ and any $v \in V_{\mathbb{R}}$, there exists $u \in U_{\mathbb{R}}$ such that $ux = x + v$. We will use this fact later.

Now we assume that \mathfrak{f}_0 is a proper subalgebra of $\mathfrak{sl}(V) \times \mathfrak{sl}(W)$. Then by Lemma 13,

$$\mathfrak{f}_0 = \{(\phi^{-1}x\phi, x) : x \in \mathfrak{sl}(W)\}$$

for some isomorphism $\phi : V \rightarrow W$. Since \mathfrak{f}_0 is an \mathbb{R} -subalgebra, ϕ can be taken to be an \mathbb{R} -map. Let $\mathfrak{a} \simeq \{a \in \text{End}(W, V)\}$ be the Lie algebra of A . The adjoint action of \mathfrak{f}_0 on \mathfrak{a} is isomorphic to adjoint action of $\mathfrak{sl}(W)$ on $\mathfrak{gl}(W)$. The isomorphism is $a \rightarrow \phi \circ a$. It follows that \mathfrak{a} has the only nontrivial \mathfrak{f}_0 -modules: $\{\lambda\phi^{-1} : \lambda \in \mathbb{C}\}$ and $\{\phi^{-1} \circ b : b \in \mathfrak{sl}(W)\}$.

Let U correspond to $\{\lambda\phi^{-1} : \lambda \in \mathbb{C}\}$. Take a basis $\{v_1, v_2\}$ of V . Then $\{v_1, v_2, \phi(v_1), \phi(v_2)\}$ is a basis of \mathbb{C}^4 , and with respect to this basis,

$$F = \left\{ \begin{pmatrix} g & \lambda g \\ 0 & g \end{pmatrix} : g \in \text{SL}(2), \lambda \in \mathbb{C} \right\}.$$

Let S be an F -invariant quadratic form. Then the subspaces V and W are totally isotropic with respect to S . Thus, the matrix of S is of the form $\begin{pmatrix} 0 & X \\ X & 0 \end{pmatrix}$ for some matrix X such that ${}^t g X g = X$ for all $g \in \text{SL}(2)$. It follows that $X = \begin{pmatrix} 0 & -u \\ u & 0 \end{pmatrix}$ for some $u \in \mathbb{C}$, and the quadratic form S is unique up to a scalar multiple. Since F is a \mathbb{Q} -group, the space of F -invariant quadratic forms is defined over \mathbb{Q} . Therefore, S is a multiple of a rational form, and $g^{-1} H g$ is contained in the \mathbb{Q} -group $\text{SO}(S)$. Now we can argue as in Case 4 when F is of type $A_1 + A_1$ (see below) to get a contradiction. Hence, we may assume that U corresponds to $\{\phi^{-1} \circ b : b \in \mathfrak{sl}(W)\}$. Then for any $x \notin V_{\mathbb{R}}$ and any $v \in V_{\mathbb{R}}$, there exists $u \in U_{\mathbb{R}}$ such that $ux = x + v$. We will use this fact later on.

Suppose that F_0 acts trivially on V . If U acts trivially on V , F has linearly independent F -invariant vectors. They correspond to distinct 3-dimensional F -invariant subspaces in \mathcal{L} . This contradicts Lemma 12. Thus, U acts nontrivially on V . Let $v_1 \in V$ be a U -fixed vector in V . Take v_2 such that $V = \langle v_1, v_2 \rangle$. Let

$$B = \{g \in \text{SL}(4, \mathbb{C}) : gv_1 = v_1, gv_2 = v_2 + tv_1, g|_W = id \text{ for } t \in \mathbb{C}\}.$$

Clearly, $U \subseteq AB$ and $U \not\subseteq A$. If $U \subseteq B$, then the subspaces V and W would be F -invariant, which contradicts Lemma 12. Thus, $U \not\subseteq B$. Let $u = ab \in U$ for $a \in A - \{1\}$ and $b \in B - \{1\}$. Note that A is abelian, and F normalizes A . Thus,

$$u^{-1}(U \cap A)u = b^{-1}(U \cap A)b \subseteq U \cap A.$$

Since the action of B is algebraic, it follows that B normalizes U . Let

$$a = \begin{pmatrix} 1 & \tilde{a} \\ 0 & 1 \end{pmatrix}$$

for some $\tilde{a} \in \text{End}(W, V) - \{0\}$ with respect to the decomposition $V \oplus W$. Since F_0 acts irreducibly on W , the restriction map $F_0 \rightarrow \text{SL}(W)$ is surjective. For $g \in \text{SL}(W)$, take $f \in F_0$ such that $f = id \oplus g$ with respect to the decomposition $V \oplus W$. Then

$$f^{-1} u f = \begin{pmatrix} 1 & \tilde{a} g \\ 0 & 1 \end{pmatrix} \cdot b \in U.$$

Thus,

$$\begin{pmatrix} 1 & \tilde{a} g - \tilde{a} \\ 0 & 1 \end{pmatrix} \in U$$

for every $g \in \text{SL}(W)$. In particular, it follows that $U \cap A \neq 1$. The only nontrivial BF_0 -submodule of A is

$$A_0 \stackrel{\text{def}}{=} \left(\begin{array}{c|c} 1 & \text{End}(W, \langle v_1 \rangle) \\ \hline 0 & 1 \end{array} \right).$$

Suppose that $U \subseteq A_0B$. Then the linear form corresponding to the projection to $\langle v_2 \rangle$ is fixed by F . This contradicts Lemma 12. Hence, there exists $a_1b_1 \in U$ for $a_1 \in A - A_0$ and $b_1 \in B$. Write

$$a_1 = \begin{pmatrix} 1 & \tilde{a}_1 \\ 0 & 1 \end{pmatrix}$$

for some $\tilde{a}_1 \in \text{End}(W, V) - \text{End}(W, \langle v_1 \rangle)$. As above,

$$\begin{pmatrix} 1 & \tilde{a}_1g - \tilde{a}_1 \\ 0 & 1 \end{pmatrix} \in U$$

for all $g \in \text{SL}(W)$. One can choose g such that $\tilde{a}_1g - \tilde{a}_1 \notin \text{End}(W, \langle v_1 \rangle)$. This shows that $U \cap A = A$. It follows that for any $x \notin V_{\mathbb{R}}$ and any $v \in V_{\mathbb{R}}$, there exists $u \in U_{\mathbb{R}}$ such that $ux = x + v$.

Finally, we finish the proof in the Case 2. By Lemma 12,

$$\mathcal{V} = \langle \alpha\ell_2 + \beta\ell_3, \ell_4 \rangle$$

for some $\alpha, \beta \in \mathbb{C}$. Let $v \neq 0$ be a vector such that

$$\ell_2(v) = \ell_3(v) = \ell_4(v) = 0.$$

Then $v \in V \cap V^\perp$, and since Q is nondegenerate, it follows that $W \not\subseteq \langle v \rangle^\perp$. Note that $L|_V = \ell_4|_V = 0$. In particular, $L|_W \neq 0$. Fix $(a, b) \in \mathbb{R}^2$. Take $z \in \mathcal{P}(\mathbb{Z}^4) - V$. Let $z = z' + z''$ for $z' \in V$ and $z'' \in W - \{0\}$. Since $L|_W \neq 0$, there exists $g \in \text{SL}(W_{\mathbb{R}})$ such that $L(gz'') = b$. We can also choose $g_n \in \text{SL}(W_{\mathbb{R}})$ such that $g_n \rightarrow g$ and $Q(g_n z'', v) \neq 0$. Take $f_n \in F_{0\mathbb{R}}^o$ such that $f_n|_{W_{\mathbb{R}}} = g_n$ and $u_n \in U_{\mathbb{R}}$ such that

$$u_n(f_n z) = f_n z + t_n v$$

where $t_n = \frac{a - Q(f_n z)}{2Q(g_n z'', v)}$. Then

$$\begin{aligned} Q(u_n f_n z) &= Q(f_n z + t_n v) = Q(f_n z) + 2t_n Q(f_n z, v) \\ &= Q(f_n z) + 2t_n Q(g_n z'', v) = a. \end{aligned}$$

Also

$$L(u_n f_n z) = L(f_n z' + f_n z'' + t_n v) = L(g_n z'') \rightarrow b.$$

This shows (6).

Case 3. $\dim \mathcal{V} = 3$. Let $V = \langle v \rangle$. By Lemma 12, $\mathcal{V} = \langle \ell_2, \ell_3, \ell_4 \rangle$. It follows that $Q(v) = 0$. Since F has no nontrivial characters, $Fv = v$. We show that W is a \mathbb{Q} -subspace. For any $\sigma \in \text{Gal}(\mathbb{C}, \mathbb{Q})$, W^σ is F_0 -invariant (because F_0 is connected). Since $W \cap W^\sigma \neq \{0\}$ and W is F_0 -irreducible, it follows that $W = W^\sigma$. Thus, W is defined over \mathbb{Q} .

For any $z \in W_{\mathbb{Z}} - \{0\}$, define

$$F_0^z = \{g \in F_{0\mathbb{R}}^o : Q(gz, v) \neq 0\}.$$

We claim that F_0^z is not empty. Suppose that $Q(gz, v) = 0$ for every $g \in F_{0\mathbb{R}}^o$. Since $F_{0\mathbb{R}}^o$ is Zariski dense in F_0 , $\langle F_{0\mathbb{R}}^o z \rangle = W_{\mathbb{R}}$. Thus, $W_{\mathbb{R}} \subseteq \langle v \rangle^\perp$. Since $Q(v) = 0$, the vector v lies in the radical of Q . This gives a contradiction. Thus, F_0^z is a nonempty

Zariski open subset of $F_{0\mathbb{R}}^o$. It follows that F_0^z is dense in $F_{0\mathbb{R}}^o$ in Euclidean topology. Put

$$F_0^\infty = \bigcap \{F_0^z : z \in \mathcal{P}(W_{\mathbb{Z}})\}.$$

This set is dense in $F_{0\mathbb{R}}^o$ by the Baire Category Theorem.

Consider the orbit $O = [L]^{F_{0\mathbb{R}}^o}$ in the real projective space $\mathbb{P}(W_{\mathbb{R}}^*)$, where $W_{\mathbb{R}}^*$ is the dual space of $W_{\mathbb{R}}$. If O consists of rational points, then $[L]^{F_{0\mathbb{R}}^o} = [L]$ and $[L]^{F_0} = [L]$, which is a contradiction. Thus, there exists $g \in F_{0\mathbb{R}}^o$ such that the linear form $L(gx)$, $x \in W$, is not proportional to a rational form. Then $L(g\mathcal{P}(W_{\mathbb{Z}}))$ is dense in \mathbb{R} . Therefore, $L(F_{0\mathbb{R}}^o\mathcal{P}(W_{\mathbb{Z}})) = \mathbb{R}$ and $L(F_0^\infty\mathcal{P}(W_{\mathbb{Z}})) = \mathbb{R}$.

Every element $u \in U$ acts on \mathbb{C}^4 as follows: $uv = v$ and for $w \in W$, $uw = w + l_u(w)v$ for some linear form l_u on W . Using this notation, the action of F_0 on U by conjugation corresponds to the usual action on the space of linear forms spanned by l_u , $u \in U$. Thus, this action is irreducible. Note that $U \neq 1$ because $\mathcal{L}^U = \mathcal{V}$. It follows that for every linear form l on W , there exists $u \in U$ such that $uw = w + l(w)v$ for $w \in W$. In particular, for any $w \in W$ and $t \in \mathbb{R}$, there exists $u \in U_{\mathbb{R}}$ such that $uw = w + tv$.

Now we are ready to finish the proof of Case 3. Fix $(a, b) \in \mathbb{R}^2$. There exist $g_n \in F_0^\infty$ and $z_n \in \mathcal{P}(W_{\mathbb{Z}})$ such that $L(g_n z_n) \rightarrow b$. Take $u_n \in U_{\mathbb{R}}$ such that $u_n g_n z_n = g_n z_n + t_n v$ where $t_n = \frac{a - Q(g_n z_n)}{2Q(g_n z_n, v)}$. Then

$$Q(u_n g_n z_n) = Q(g_n z_n + t_n v) = Q(g_n z_n) + 2t_n Q(g_n z_n, v) = a$$

and

$$L(u_n g_n z_n) = L(g_n z_n) \rightarrow b.$$

This shows (6).

Case 4. $\dim \mathcal{V} = 4$. By Lemma 8, F is semisimple. From Table 1, F is one of the types A_1 , $A_1 + A_1$, C_2 . The first case is impossible because F contains a 2-dimensional unipotent subgroup. Denote by \mathfrak{f} the Lie algebra of F .

Let F be of type C_2 . Then $\mathfrak{f} = \mathfrak{gsp}(4, \mathbb{C})g^{-1}$ for some $g \in \mathrm{SL}(4, \mathbb{C})$. Equivalently, $\mathfrak{f} = \mathfrak{sp}(S, \mathbb{C})$ for a nondegenerate symplectic form S over \mathbb{C} . The form S is proportional to a real form because F is defined over \mathbb{R} . Fix $(a, b) \in \mathbb{R}^2$. By Lemma 3, there exists $x \in \mathbb{R}^4$ such that $Q(x) = a$ and $L(x) = b$. Take $x_n \in \mathbb{Q}^4 - \{0\}$ such that $x_n \rightarrow x$, and $y_n \in \mathbb{Q}^4 - \langle x_n \rangle$ such that $S|_{\langle x_n, y_n \rangle}$ is nondegenerate. Let $V_n = \langle x_n, y_n \rangle$. Take $z_n \in \mathcal{P}(V_n\mathbb{Z})$. Every element of the form $g \oplus id$ for $g \in \mathrm{SL}(V_n\mathbb{R})$ with respect to decomposition $V_n \oplus V_n^\perp$ is in $\mathrm{Sp}(S, \mathbb{R})$ for any $g \in \mathrm{SL}(V_n\mathbb{R})$. Thus, there exists $f_n \in F_{\mathbb{R}}^o = \mathrm{Sp}(S, \mathbb{R})$ such that $x_n = f_n z_n$. Then $Q(f_n z_n) \rightarrow a$ and $L(f_n z_n) \rightarrow b$. This shows (6).

Let F be of type $A_1 + A_1$. Using an argument as in Proposition 7, $F = \mathrm{SO}(S)$ for some real nondegenerate quadratic form S .

Let \mathfrak{h} be the Lie algebra of H . It is easy to check that the normalizer of \mathfrak{h} in $\mathfrak{sl}(4, \mathbb{C})$ is

$$(7) \quad \left\{ \begin{pmatrix} u & x & y & t \\ 0 & v & 0 & y \\ 0 & 0 & -v & x \\ 0 & 0 & 0 & -u \end{pmatrix} : u, v, x, y, t \in \mathbb{C} \right\},$$

and the centralizer of \mathfrak{h} in $\mathfrak{sl}(4, \mathbb{C})$ is

$$(8) \quad \left\{ \begin{pmatrix} 0 & x & y & t \\ 0 & 0 & 0 & y \\ 0 & 0 & 0 & x \\ 0 & 0 & 0 & 0 \end{pmatrix} : x, y, t \in \mathbb{C} \right\}.$$

Since $F_{\mathbb{R}}$ contains a closed unipotent subgroup $g^{-1}H_{\mathbb{R}}g$, it cannot be compact. Thus, $F_{\mathbb{R}}$ is isomorphic to either $SO(3, 1)_{\mathbb{R}}$ or $SO(2, 2)_{\mathbb{R}}$. Recall that $SO(3, 1)_{\mathbb{R}}$ is isogenous to $SL(2, \mathbb{C})$, and $SO(2, 2)_{\mathbb{R}}$ is isogenous to $SL(2, \mathbb{R}) \times SL(2, \mathbb{R})$. In both cases, the group $g^{-1}H_{\mathbb{R}}g$ is a maximal unipotent subgroup of F . Let $\mathfrak{h}_{\mathbb{R}}$ be the Lie algebra of $H_{\mathbb{R}}$. Consider the map

$$\phi : N_{SL(4, \mathbb{R})}(gH_{\mathbb{R}}g^{-1})^{\circ} \rightarrow GL(\text{Ad}(g)\mathfrak{h}_{\mathbb{R}})$$

defined by $\phi(n)h = \text{Ad}(n)h$. By (7) and (8), the image of ϕ is isogenous to $\mathbb{R}_{>0} \times \mathbb{R}_{>0}$. If $F_{\mathbb{R}}$ were isogenous to $SL(2, \mathbb{C})$, then $\phi(N_{F_{\mathbb{R}}}(gH_{\mathbb{R}}g^{-1})^{\circ})$ would be isogenous to $\mathbb{C}^{\times} \simeq SO(2, \mathbb{R}) \times \mathbb{R}_{>0}$. To check the last statement, one can note that it is obvious when $g^{-1}H_{\mathbb{R}}g$ is the subgroup of upper unipotent matrices in $SL(2, \mathbb{C})$, and $g^{-1}H_{\mathbb{R}}g$ is conjugate to this subgroup. This shows that S has signature $(2, 2)$.

Denote $E = SO(Q_0)$ and $G = SL(4, \mathbb{C})$. Then $F = g^{-1}g_1^{-1}Eg_1g$ for some $g_1 \in G$. First, we show that $g_1 \in EC_G(H)$. We have H and $g_1Hg_1^{-1} \subseteq E$. Since maximal unipotent subgroups are conjugate, $eHe^{-1} = g_1Hg_1^{-1}$ for some $e \in E$. Thus, $e^{-1}g_1 \in N_G(H)$, and $g_1 \in EN_G(H)$. Without loss of generality, $g_1 \in N_G(H)$. Consider the map $\psi : N_G(H) \rightarrow GL(\mathfrak{h})$ defined by $\psi(n)h = \text{Ad}(n)h$. Since this map is algebraic, its image is an algebraic subgroup in $GL(\mathfrak{h})$. By (7) and (8), $\dim \psi(N_G(H)) = 2$ and $\psi(N_G(H))^{\circ}$ is generated by diagonal matrices. Thus, $\psi(N_G(H))^{\circ}$ is abelian. Let

$$T = \{\text{diag}(u, v, v^{-1}, u^{-1}) : u, v \in \mathbb{C}^{\times}\}.$$

This is a maximal torus of E . Since $\psi(T)$ has dimension 2, it is a maximal torus of $GL(\mathfrak{h})$, and so is $\psi(g_1^{-1}Tg_1)$. Since they commute,

$$\psi(g_1)^{-1}\psi(T)\psi(g_1) = \psi(T),$$

i.e. $\psi(g_1)$ normalizes $\psi(T)$. The normalizer of $\psi(T)$ in $GL(\mathfrak{h})$ is generated by $\psi(T)$ and the transformation that permutes two elements of the basis of \mathfrak{h} . It is easy to see that this transformation is in $\psi(E)$. Thus, $\psi(g_1) \in \psi(E)$. Since $\ker \psi = C_G(H)$, it follows that $g_1 \in EC_G(H)$.

It follows from Lemma 12 that H has a unique fixed vector v (up to a scalar multiple). Then for $c \in C_G(H)$, $cv = \lambda v$ for some $\lambda \in \mathbb{C}$. Suppose that $\mu \in \mathbb{C} - \{\lambda\}$ is an eigenvalue of c . The complex eigenspace corresponding to μ and λ are H -invariant. Each of these subspaces contains a nonzero vector fixed by H (because H is unipotent). This contradicts Lemma 12. Thus, c has a unique eigenvalue, and $c = (\lambda I)c_0$, where I is the identity matrix and $c_0 \in C_G(H)$ is unipotent. Let C_0 be the set of unipotent elements of $C_G(H)$. If $c_1, c_2 \in C_0$, $c_1v = c_2v = v$, and $c_1c_2^{-1}v = v$, then $c_1c_2^{-1}$ is unipotent. Thus, C_0 is a subgroup. We have $C_G(H) = Z(G)C_0$. Clearly, C_0 is unipotent algebraic subgroup, so that it is connected. By

(8), $C_0 = Hu_{\mathbb{C}}$, where

$$u_t = \begin{pmatrix} 1 & 0 & 0 & t \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix}.$$

Thus, $g_1 \in EZ(G)u_{\mathbb{C}}$. Then

$$\begin{aligned} F &= g^{-1}g_1^{-1}Eg_1g = g^{-1}u_t^{-1}\text{SO}(Q_0)u_tg = g^{-1}\text{SO}(Q_0 + tx_4^2)g \\ &= \text{SO}(Q + tL^2) \end{aligned}$$

for some $t \in \mathbb{C}$. Since F is a \mathbb{Q} -group, the quadratic form $Q + tL^2$ is proportional to a rational form. This is a contradiction. The proposition is proved. \square

6. CONCLUSION

Let (Q, L) be a pair such that Q is a nondegenerate quadratic form and L is a nonzero linear form. It would be interesting to obtain necessary and sufficient conditions for the property

$$\overline{\{(Q(x), L(x)) : x \in \mathcal{P}(\mathbb{Z}^d)\}} = \mathbb{R}^2$$

to hold. In this context, we formulate the following conjecture:

Conjecture 15. *Let Q be a nondegenerate quadratic form, and let L be a nonzero linear form in dimension $d \geq 4$. Suppose that*

- (1) *For every $\beta \in \mathbb{R}$, $Q + \beta L^2$ is indefinite.*
- (2) *For every $(\alpha, \beta) \neq (0, 0)$, with $\alpha, \beta \in \mathbb{R}$, $\alpha Q + \beta L^2$ is not rational.*

Then $\{(Q(x), L(x)) : x \in \mathcal{P}(\mathbb{Z}^d)\}$ is dense in \mathbb{R}^2 .

The first condition in the conjecture is necessary for the density to hold. Indeed, suppose that $Q + \beta L^2$ is definite (say, positive definite) for some $\beta \in \mathbb{R}$. By Proposition 2,

$$(9) \quad Q = \ell_1^2 + \dots + \ell_{d-1}^2 - \beta \ell_d^2 \text{ and } L = \ell_d$$

for some linearly independent linear forms $\ell_i, i = 1, \dots, d$. If $\bar{0} \in \mathbb{R}^2$ is an accumulation point of the set $\{(Q(x), L(x)) : x \in \mathbb{Z}^d\}$, then $\bar{0} \in \mathbb{R}^d$ is an accumulation point of the set $\{(\ell_1(x), \dots, \ell_d(x)) : x \in \mathbb{Z}^d\}$ which is impossible.

Due to Theorem 1, it remains to prove Conjecture 15 in the case when (Q, L) is of type (II), and $Q|_{L=0}$ is positive definite, i.e.

$$(10) \quad Q = \ell_1^2 + \dots + \ell_{d-2}^2 + \ell_{d-1}\ell_d \text{ and } L = \ell_d$$

for some linearly independent linear forms $\ell_i, i = 1, \dots, d$. The method of the proof of Proposition 14 with minor modifications allows us to prove Conjecture 15 in dimension 4. However, one should keep in mind that the method of reduction to lower dimension (Proposition 4) fails to work in this case. Namely, for every $d \geq 4$, there exist pairs (Q, L) of dimension d that satisfy the conditions of Conjecture 15, but for every rational subspace V of codimension 1, the set $\{(Q(x), L(x)) : x \in V_{\mathbb{Z}}\}$ is not dense in \mathbb{R}^2 . To construct such an example, we take a pair (Q, L) as in (10) such that the space $\langle \ell_1, \dots, \ell_{d-2}, \ell_d \rangle$ contains no nonzero rational forms, and (Q, L) satisfies the second condition of Conjecture 15. Clearly, such pairs exist. In fact, such pairs are generic in a suitable sense. Let ℓ be a nonzero rational form. It is easy to see from Lemma 4 that the pair $(Q|_{\ell=0}, L|_{\ell=0})$ is of type (II) iff $Q|_W$ is

degenerate where W is the space $\{\ell = 0, L = 0\}$. The forms $\ell_i|_W$, $i = 1, \dots, d - 2$, are linearly independent because $\ell \notin \langle \ell_1, \dots, \ell_{d-2}, \ell_d \rangle$. Therefore,

$$Q|_W = (\ell_1^2 + \dots + \ell_{d-2}^2)|_W$$

is nondegenerate, and $(Q|_{\ell=0}, L|_{\ell=0})$ is of type (I). Since $Q|_{L=0}$ is positive definite, the pair $(Q|_{\ell=0}, L|_{\ell=0})$ is as in (9). As we saw above, density fails in this case.

ACKNOWLEDGMENT

The author is deeply grateful to his advisor V. Bergelson for suggesting the problem as well as for many helpful discussions.
