A COSTA-HOFFMAN-MEEKS TYPE SURFACE IN $\mathbb{H}^2 \times \mathbb{R}$

FILIPPO MORABITO

ABSTRACT. We show the existence in the space $\mathbb{H}^2 \times \mathbb{R}$ of a family of embedded minimal surfaces of genus $1 \leq k < +\infty$ and finite total extrinsic curvature with two catenoidal type ends and one middle planar end. The proof is based on a gluing procedure.

1. Introduction

During recent years the study of the minimal surfaces in the product spaces $M \times \mathbb{R}$ with $M = \mathbb{H}^2$, $\mathbb{S}^2$ has become more and more active. The development of the theory of the minimal surfaces in these spaces started with [20] by H. Rosenberg and continued with [14] and [15] by W. H. Meeks and H. Rosenberg. In [17] B. Nelli and H. Rosenberg showed the existence in $\mathbb{H}^2 \times \mathbb{R}$ of a rich family of examples including helicoids, catenoids and, solving Plateau problems, of higher topological type examples inspired by the theory of minimal surfaces in $\mathbb{R}^3$. In [5] L. Hauswirth constructed and classified the minimal surfaces foliated by horizontal constant curvature curves in $M \times \mathbb{R}$, where $M$ is $\mathbb{H}^2$, $\mathbb{R}^2$ or $\mathbb{S}^2$. Other examples of minimal surfaces of genus 0 in these product manifolds are described by R. Sa Earp and E. Toubiana in [21].

C. Costa in [1, 2] and D. Hoffman and W. H. Meeks in [7], [8] and [9] described a minimal surface in $\mathbb{R}^3$ of genus $1 \leq k < +\infty$ and finite total curvature with two ends asymptotic to the two ends of a catenoid and a middle end asymptotic to a plane. We will denote the Costa-Hoffman-Meeks surface of genus $k$ by $M_k$.

The aim of this work is to show the existence in the space $\mathbb{H}^2 \times \mathbb{R}$ of a family of surfaces inspired by $M_k$. We will prove the following result.

Theorem 1.1. For all $1 \leq k < +\infty$ there exists in $\mathbb{H}^2 \times \mathbb{R}$ a one-parameter family of embedded minimal surfaces of genus $k$ and finite total extrinsic curvature with three horizontal ends: two catenoidal type ends and a middle planar end.

We will observe that it is more convenient to construct a minimal surface enjoying the same properties mentioned in the statement of theorem in the Riemannian manifold $(\mathbb{D}^2 \times \mathbb{R}, g_{hyp})$ where $g_{hyp} = \frac{dx_1^2 + dx_2^2}{(1-x_1^2-x_2^2)^\tau} + dx_3^2$. It is usually denoted by $M^2(-4) \times \mathbb{R}$, to point out that the sectional curvature of $\mathbb{D}^2 \times \{0\}$ endowed with the metric $\frac{dx_1^2 + dx_2^2}{(1-x_1^2-x_2^2)^\tau}$ equals $-4$. We observe that $\mathbb{H}^2 = M^2(-1)$. Once having constructed this surface, it is easy to obtain by a diffeomorphism the wanted minimal surface in $\mathbb{H}^2 \times \mathbb{R}$.

The main result is proved by a gluing procedure (see for example [6]) usually adopted to construct in $\mathbb{R}^3$ new examples starting from known minimal surfaces. We consider a scaled version of a compact piece of a Costa-Hoffman-Meeks type surface, which is contained in a cylindrical neighbourhood of $\{0,0\} \times \mathbb{R} \subset \mathbb{M}^2(-4) \times \mathbb{R}$ of sufficiently small radius. Actually it’s possible to prove that, in the same set, the mean curvature of such a surface with respect to the metric $g_{hyp}$, up to an infinitesimal term, equals the Euclidean one. We glue the surface described above along its three boundary curves to two minimal graphs that are respectively asymptotic to an upper half catenoid and a lower half catenoid defined in $\mathbb{M}^2(-4) \times \mathbb{R}$ and to a minimal graph over $\mathbb{M}^2(-4) \times \{0\}$ which goes to zero in a neighbourhood of $\partial_\infty \mathbb{M}^2(-4) \times \{0\}$. The existence of these surfaces is proved in sections 5 and 7.

The author wishes to thank his thesis director, L. Hauswirth, for having brought this problem to his attention.

2. Preliminaries

In this work we will consider the unit disk model for $\mathbb{H}^2$. Let $(x_1,x_2)$ denote the coordinates in the unit disk $D^2$ and $x_3$ the coordinate in $\mathbb{R}$. Then the space $D^2 \times \mathbb{R}$ is endowed with the metric

$$g_{\mathbb{H}^2 \times \mathbb{R}} = \frac{4(dx_1^2 + dx_2^2)}{(1 - x_1^2 - x_2^2)^2} + dx_3^2.$$  

As mentioned in the Introduction, one of the surfaces involved in the gluing procedure is a compact piece of a scaled version of the Costa-Hoffman-Meeks surface, that is, a minimal surface in $\mathbb{R}^3$ endowed with the Euclidean metric $g_0$. To simplify as much as possible the proof of the main theorem, it is convenient to consider a Riemannian manifold endowed with a metric more similar to $g_0$ than the standard metric of $\mathbb{H}^2 \times \mathbb{R}$. The best choice is

$$g_{hyp} = \frac{dx_1^2 + dx_2^2}{(1 - x_1^2 - x_2^2)^2} + dx_3^2,$$

because $g_{hyp} \to g_0$ if $(x_1,x_2) \to (0,0)$. This is the reason that induces us to give a proof of Theorem [1] working in the Riemannian manifold $\mathbb{M}^2(-4) \times \mathbb{R}$. Now we suppose to have shown the existence of a minimal surface in this Riemannian manifold. We need to show how it is possible to obtain a minimal surface in $\mathbb{H}^2 \times \mathbb{R}$. Let $\bar{g}$ be the metric defined on $D^2 \times \mathbb{R}$ by

$$\bar{g} = 4g_{hyp} = \frac{4(dx_1^2 + dx_2^2)}{(1 - x_1^2 - x_2^2)^2} + 4dx_3^2.$$  

We consider the map $f : (D^2 \times \mathbb{R}, g_{\mathbb{H}^2 \times \mathbb{R}}) \to (D^2 \times \mathbb{R}, \bar{g})$ defined by

$$(1) \quad (x_1,x_2,x_3) \to \left( x_1, x_2, \frac{x_3}{4} \right).$$  

It is easy to see that it is an isometric embedding, that is, the pull-back of the metric $\bar{g}$ by $f$ equals $g_{\mathbb{H}^2 \times \mathbb{R}}$. So if $\Sigma$ is a minimal surface in $(D^2 \times \mathbb{R}, \bar{g})$, then the image of $\Sigma$ by $f^{-1}$ is a minimal surface in $\mathbb{H}^2 \times \mathbb{R}$.

Now we turn our attention to the Riemannian manifold $\mathbb{M}^2(-4) \times \mathbb{R}$, mentioned in the Introduction. In the following we will adopt the simplified notation $\mathbb{M}^2 \times \mathbb{R}$. We recall that the metric $\bar{g}$ has been defined as $4g_{hyp}$, $g_{hyp}$ being the metric of $\mathbb{M}^2 \times \mathbb{R}$. As a consequence the mean curvature of a surface $\Sigma$ in $\mathbb{M}^2 \times \mathbb{R}$ equals the
mean curvature of Σ in \((\mathbb{D}^2 \times \mathbb{R}, \tilde{g})\) multiplied by 4. So if a surface is minimal in \(\mathbb{M}^2 \times \mathbb{R}\), it is also minimal with respect to the metric \(\tilde{g}\).

We can conclude that if \(\Sigma\) is a minimal surface in \(\mathbb{M}^2 \times \mathbb{R}\), then \(f^{-1}(\Sigma)\) is a minimal surface in \(\mathbb{H}^2 \times \mathbb{R}\).

**Remark 2.1.** To prove Theorem 1.1 we will need to consider spaces of functions invariant under the actions of the isometries of \(\mathbb{M}^2 \times \mathbb{R}\). We denote by (6) the mean curvature of \(\Sigma\) in \((\mathbb{D}^2 \times \mathbb{R}, \tilde{g})\) multiplied by 4. So if a surface is minimal in \(\mathbb{M}^2 \times \mathbb{R}\), it is also minimal with respect to the metric \(\tilde{g}\).

3. Minimal graphs in \(\mathbb{M}^2 \times \mathbb{R}\)

We denote by \(H_u\) the mean curvature of the graph of the function \(u\) over a domain in \(\mathbb{D}^2\). Its expression is

\[
2H_u = F \text{div} \left( \frac{\nabla u}{\sqrt{1 + F|\nabla u|^2}} \right),
\]

where \(F = (1 - x_1^2 - x_2^2)^2 = (1 - r^2)^2\) and \(\text{div}\) denotes the divergence in \(\mathbb{R}^2\). For the details of the computation, see subsection [2,3].

Let \(\Sigma_u\) be the graph of the function \(u\). In this section we want to obtain the expression of the mean curvature of the surface \(\Sigma_{u+v}\), that is, the graph of the function \(u + v\). It can also be considered as the vertical graph of the function \(v\) over \(\Sigma_u\). We will show how it follows from (2) that the linearized mean curvature, which we denote by \(L_{uv}\), is given locally by:

\[
L_{uv} := F \text{div} \left( \frac{\nabla v}{\sqrt{1 + F|\nabla u|^2}} - F\nabla u \cdot \nabla v \frac{\nabla u \cdot \nabla v}{\sqrt{(1 + F|\nabla u|^2)^3}} \right).
\]

Furthermore we will give the expression of \(H_{u+v}\), the mean curvature of the graph of the function \(u + v\), in terms of the mean curvature of \(\Sigma_u\), that is, \(H_u\). In the following we will restrict our attention to two cases: the plane (in section 5), that is, \(u = 0\), and (in section 6) a piece of catenoid defined on the domain \(\{(\theta, r) \in \mathbb{M}^2 \times \{0\} \mid r \in [r_\varepsilon, 1]\}\), where \(r_\varepsilon = \varepsilon/2\).

Here we will show that:

\[
2H_{u+v} = 2H_u + L_{uv} + FQ_u(\sqrt{F}\nabla v, \sqrt{F} \nabla^2 v),
\]

where \(Q_u\) has bounded coefficients if \(r \in [r_\varepsilon, 1]\) and it satisfies \(Q_u(0,0) = 0\) and \(\nabla Q_u(0,0) = 0\). To show this, we observe that

\[
\frac{1}{\sqrt{1 + F|\nabla (u + v)|^2}} = \frac{1}{\sqrt{1 + F|\nabla u|^2}} - \frac{F \nabla u \cdot \nabla v}{(1 + F|\nabla u|^2)^{3/2}} + Q_{u,1}(v).
\]

\(Q_{u,1}(v)\) has the following expression:

\[
\frac{-F|\nabla v|^2}{2(1 + F|\nabla (u + tv)|^2)^{3/2}} + \frac{3F^2(\nabla u \cdot \nabla v + t|\nabla v|^2)^2}{2(1 + F|\nabla (u + tv)|^2)^{5/2}},
\]

with \(t \in (0,1)\), and it satisfies \(Q_{u,1}(0) = 0, \nabla Q_{u,1}(0) = 0\). To prove \(\text{5}\) it’s sufficient to set

\[
f(t) = \frac{1}{\sqrt{1 + F|\nabla (u + tv)|^2}}
\]
and to write down the Taylor’s series of order one of this function and to evaluate it in \( t = 1 \). That is, \( f(1) = f(0) + f'(0) + \frac{1}{2} f''(\bar{t}) \), with \( \bar{t} \in (0, 1) \). We insert (5) in the expression that defines \( 2H_{u+v} \) to get

\[
F \text{div} \left( \frac{\nabla(u + v)}{\sqrt{1 + F \sqrt{|\nabla u|^2}}} - F \nabla u \cdot \nabla v \sqrt{(1 + F \sqrt{|\nabla u|^2})^3} + \nabla(u + v)Q_{u,1}(v) \right) = 2H_u + F \text{div} \left( \frac{\nabla v}{\sqrt{1 + F \sqrt{|\nabla u|^2}}} - F \nabla u \cdot \nabla v \sqrt{(1 + F \sqrt{|\nabla u|^2})^3} \right) + FQ_u(\sqrt{F \nabla v}, \sqrt{F \nabla^2 v}).
\]

Since we assume that \( \Sigma_u \) is a minimal surface, we will consider \( H_u = 0 \).

**Remark 3.1.** The minimal surfaces in the families we will construct in sections 5 and 7 have finite total extrinsic curvature. These minimal surfaces are graphs over the domain \( \{(\theta, r) \in M^2 \mid r \in [r_\varepsilon, 1]\} \) of functions of class \( C^{2,\alpha} \). The total extrinsic curvature of the graph \( S \) of a function \( u \) defined on \( M^2 \) is the integral of the extrinsic curvature, that is,

\[
(7) \quad \int_S K_{\text{ext}} dA = \int_S \frac{I}{I} dA,
\]

where \( I, II \) denote the determinants of the first and of the second fundamental form. It follows that \( II = b_{11}b_{22} - b_{12}^2 \), \( I = g_{11}g_{22} - g_{12}^2 \), \( dA = \sqrt{I} \). For the expressions of the coefficients of the first and of the second differential form see subsection 12.3. Once their expressions have been replaced in (7), it is clear that, taking into account that \( u \) is a \( C^{2,\alpha} \) class function, \( \int_S K_{\text{ext}} dA \) is bounded. This observation allows us to state that this property also holds for the surface obtained by a gluing procedure in section 11. In fact the total extrinsic curvature of this last surface equals the sum of the total extrinsic curvature of the surfaces glued together, that is, a compact piece of a Costa-Hoffman-Meeks type surface and three minimal graphs over the domain described above. Because of the compactness, the contribution to the total curvature of the piece of the Costa-Hoffman-Meeks type example is bounded. Then the result follows immediately, taking into account the observation made above concerning the graph of \( C^{2,\alpha} \) class functions over \( M^2 \).

4. **THE MAPPING PROPERTIES OF THE LAPLACE OPERATOR**

Now we restrict our attention to the case of the minimal surfaces close to \( M^2 \times \{0\} \), that is, the graph of the function \( u = 0 \). In this case we obtain immediately from (3) that \( L_{u=0} = F\Delta_0 \), where \( \Delta_0 \) denotes the Laplacian in the flat metric \( g_0 \) of the unit disk \( \mathbb{D}^2 \).

In this section we will study the mapping properties of \( \Delta_0 \). In the sequel we will use the polar coordinates \((\theta, r)\).

In particular our aim is to solve in a unique way the problem:

\[
\begin{cases}
\Delta_{g_0} w = f & \text{in } S^1 \times [r_0, 1], \\
w|_{r=r_0} = \varphi & \text{on } S^1 \times \{r_0\},
\end{cases}
\]

with \( r_0 \in (0, 1) \), considering a convenient normed functions space for \( w, f \) and \( \varphi \), so that the norm of \( w \) is bounded by that of \( f \).

Now we can give the definition of the space of functions we will consider.
**Definition 4.1.** Given \( \ell \in \mathbb{N} \), \( \alpha \in (0,1) \), and the closed interval \( I \subset [0,1] \), we define

\[
C^{\ell,\alpha}(S^1 \times I)
\]

to be the space of functions \( w := w(\theta,r) \) in \( C^{\ell,\alpha}_{loc}(S^1 \times I) \) for which the norm

\[
||w||_{C^{\ell,\alpha}(S^1 \times I)}
\]

is finite and whose graph surfaces are invariant with respect to symmetry with respect to the \( x_2 = 0 \) plane, with respect to the rotation of an angle \( \frac{2\pi}{k+1} \) about the vertical \( x_3 \)-axis, with respect to the composition of a rotation of angle \( \frac{\pi}{k+1} \) about the \( x_3 \)-axis and the symmetry with respect to the \( x_3 = 0 \) plane.

We recall that one of the surfaces involved in the gluing procedure we will follow to prove the main theorem is a surface derived by the Costa-Hoffman-Meeks surface. This surface, as explained in subsection 9.1, enjoys many properties of symmetry that we want to be inherited by the surface obtained by the gluing procedure. This is the reason for which we have chosen the functional space described above.

**Proposition 4.2.** Given \( r_0 \in (0,1) \), there exists an operator

\[
G_{r_0} : C^{0,\alpha}(S^1 \times [r_0,1]) \rightarrow C^{2,\alpha}(S^1 \times [r_0,1])
\]

satisfying the following statements:

(i) \( \Delta_0 w = f \) on \( S^1 \times [r_0,1] \),
(ii) \( w = 0 \) on \( S^1 \times \{r_0\} \) and \( S^1 \times \{1\} \),
(iii) \( ||w||_{C^{2,\alpha}(S^1 \times [r_0,1])} \leq c ||f||_{C^{0,\alpha}(S^1 \times [r_0,1])} \), for some constant \( c > 0 \) which does not depend on \( r_0, f \) and \( w \).

The proof of this result is contained in subsection 12.2.

5. A FAMILY OF MINIMAL SURFACES CLOSE TO \( M^2 \times \{0\} \)

In this section we will show the existence of minimal graphs in \( M^2 \times \mathbb{R} \) over \( \mathbb{D}^2 - B_{r_0} \), having prescribed boundary and which are asymptotic to it. We recall that \( r_0 = \varepsilon / 2 \). We will reformulate the problem to use the Schauder fixed point theorem. We know already that the graph of a function \( v \), denoted with \( \Sigma_v \), is minimal, if and only if the function \( v \) is a solution of

\[
F \left( \Delta_0 v + Q_0 \left( \sqrt{F} \nabla v, \sqrt{F} \nabla^2 v \right) \right) = 0.
\]

This equation is a simplified version (since \( u = 0 \)) of (1). The operator \( Q_0 \) has bounded coefficients for \( r \in [r_\varepsilon,1] \). Its expression is \( \text{div} (\nabla v Q_{0,1}) \), where \( Q_{0,1} \) is given by (3). To simplify the notation, in the sequel we will write \( Q_0(\cdot) \) in place of \( Q_0 \left( \sqrt{F} \nabla, \sqrt{F} \nabla^2 \right) \).

Now let’s consider a function \( \varphi \in C^{2,\alpha}(S^1) \) which is even with respect to \( \theta \), collinear to \( \cos(j(k+1)\theta) \) (for \( k \geq 1 \) fixed) with \( j \geq 1 \) and odd and such that

\[
||\varphi||_{C^{2,\alpha}} \leq \kappa \varepsilon^2.
\]

We define

\[
w_{\varphi}(\cdot,\cdot) := \mathcal{H}_{r_\varepsilon,\varphi}(\cdot,\cdot),
\]

where \( \mathcal{H} \) is the operator of harmonic extension introduced in Proposition 12.1. The particular choice of \( \varphi \) assures that its harmonic extension belongs to the functional space of Definition 4.1.
In order to solve equation (9), we look for $v$ of the form $v = w_\varphi + w$, where $w \in C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])$ and $v = \varphi$ on $S^1 \times \{r_\varepsilon\}$. Using Proposition 4.2, we can rephrase this problem as a fixed point problem,

\begin{equation}
(10) \quad w = S(\varphi, w),
\end{equation}

where the nonlinear mapping $S$ which depends on $\varepsilon$ and $\varphi$ is defined by

\begin{equation}
S(\varphi, w) := -G_{r_\varepsilon}(Q_0(w_\varphi + w)),
\end{equation}

and where the operator $G_{r_\varepsilon}$ is defined in Proposition 4.2. To prove the existence of a fixed point for (10), we need the following result, which states that $S(\varphi, \cdot)$ is a contraction mapping:

**Lemma 5.1.** Let $\varphi \in C^{2,\alpha}(S^1)$ be a function satisfying (9) and enjoying the properties given above. There exist some constants $c_\kappa > 0$ and $\varepsilon_\kappa > 0$ such that

\begin{equation}
(11) \quad \|S(\varphi, 0)\|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])} \leq c_\kappa \varepsilon^4
\end{equation}

and, for all $\varepsilon \in (0, \varepsilon_\kappa)$,

\begin{align*}
\|S(\varphi, v_2) - S(\varphi, v_1)\|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])} &\leq \frac{1}{2} \|v_2 - v_1\|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])}, \\
\|S(\varphi_2, v) - S(\varphi_1, v)\|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])} &\leq c_\kappa \|\varphi_2 - \varphi_1\|_{C^{2,\alpha}(S^1)}.
\end{align*}

where $c$ is a positive constant, for all $v_1, v_2 \in C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])$ such that $\|v_1\|_{C^{2,\alpha}} \leq 2c_\kappa \varepsilon^4$ and for all boundary data $\varphi_1, \varphi_2 \in C^{2,\alpha}(S^1)$ enjoying the same properties as $\varphi$.

**Proof.** We know from Proposition 4.2 that $\|G_{r_\varepsilon}(f)\|_{C^{2,\alpha}} \leq c\|f\|_{C^{0,\alpha}}$. Then

\begin{equation}
\|S(\varphi, 0)\|_{C^{2,\alpha}} = \|G_{r_\varepsilon}(Q_0(w_\varphi))\|_{C^{2,\alpha}} \leq c\|Q_0(w_\varphi)\|_{C^{0,\alpha}}.
\end{equation}

To find an estimate of the norm above we recall that $\|\varphi\|_{C^{2,\alpha}} \leq \kappa \varepsilon^2$ and thanks to Proposition 12.1 we obtain

$$\|w_\varphi\|_{C^{2,\alpha}} \leq c\|\varphi\|_{C^{2,\alpha}} \leq c_\kappa \varepsilon^2.$$  

Then

$$\|Q_0(w_\varphi)\|_{C^{0,\alpha}} \leq c\|w_\varphi\|_{C^{2,\alpha}} \leq c\|\varphi\|_{C^{2,\alpha}} \leq c_\kappa \varepsilon^4.$$  

So we can conclude

$$\|S(\varphi, 0)\|_{C^{2,\alpha}} \leq c_\kappa \varepsilon^4.$$  

As for the second estimate, we observe that

$$\|S(\varphi, v_2) - S(\varphi, v_1)\|_{C^{2,\alpha}} \leq c\|Q_0(w_\varphi + v_2) - Q_0(w_\varphi + v_1)\|_{C^{0,\alpha}}.$$  

Thanks to the considerations made above it follows that

$$\|Q_0(w_\varphi + v_2) - Q_0(w_\varphi + v_1)\|_{C^{0,\alpha}} \leq c\|v_2 - v_1\|_{C^{2,\alpha}} \|w_\varphi\|_{C^{2,\alpha}}$$  

$$\leq c_\kappa \varepsilon^2\|v_2 - v_1\|_{C^{2,\alpha}}.$$  

Then

$$\|S(\varphi, v_2) - S(\varphi, v_1)\|_{C^{2,\alpha}} \leq c_\kappa \varepsilon^2\|v_2 - v_1\|_{C^{2,\alpha}}.$$  

To show the third estimate we proceed as above:

$$\|S(\varphi_2, v) - S(\varphi_1, v)\|_{C^{2,\alpha}} \leq c\|Q_0(w_{\varphi_2} + v) - Q_0(w_{\varphi_1} + v)\|_{C^{0,\alpha}}$$  

$$\leq c\|w_{\varphi_2} - w_{\varphi_1}\|_{C^{2,\alpha}} \|v\|_{C^{2,\alpha}} \leq c\varepsilon^2\|\varphi_2 - \varphi_1\|_{C^{2,\alpha}}.$$  

\qed
Theorem 5.2. Let \( B := \{ w \in C^{2,\alpha}(S^1 \times [r_e, 1]) \mid ||w||_{C^{2,\alpha}} \leq 2c_\epsilon \epsilon^4 \} \) and \( \varphi \) be as above. Then the nonlinear mapping \( S(\varphi, \cdot) \) defined above has a unique fixed point \( v \) in \( B \).

Proof. The previous lemma shows that, if \( \epsilon \) is chosen small enough, the nonlinear mapping \( S(\varphi, \cdot) \) is a contraction mapping from the ball \( B \) of radius \( 2c_\epsilon \epsilon^4 \) in \( C^{2,\alpha}(S^1 \times [r_e, 1]) \) into itself. This value follows from the estimate of the norm of \( S(\varphi, 0) \). Consequently, thanks to the Schauder fixed point theorem, \( S(\varphi, \cdot) \) has a unique fixed point \( v \) in this ball. \( \square \)

We have proved the existence of a minimal surface with respect to the metric \( g_{hyp} \), denoted by \( S_m(\varphi) \), which is close to \( \mathbb{B}^2 - B_{r_e} \subset \mathbb{M}^2 \times \{0\} \), and close to its boundary is the vertical graph over the annulus \( B_{2r_e} - B_{r_e} \) of a function which can be expanded as

\[
\hat{U}_m(\theta, r) = \mathcal{H}_{r,\varphi}(\theta, r) + \tilde{V}_m(\theta, r), \quad \text{with} \quad ||\tilde{V}_m||_{C^{2,\alpha}} \leq c\epsilon^2. 
\]

From the properties of the extension operator \( \mathcal{H}_{r,\varphi} \) (see Proposition \[12.1\]) and Proposition \[12.2\] we can see that \( \hat{U}_m(\theta, r) \) tends to 0 as \( r \to 1 \). In other terms \( S_m(\varphi) \) is asymptotic to \( \mathbb{M}^2 \times \{0\} \). Furthermore it is clear that \( S_m(\varphi) \) is embedded in \( \mathbb{M}^2 \times \mathbb{R} \).

The function \( \tilde{V}_m \) depends nonlinearly on \( \epsilon, \varphi \). Furthermore, as it is easy to prove thanks to the third estimate of Lemma \[5.1\] it satisfies

\[
(12) \quad ||\tilde{V}_m(\epsilon, \varphi)(r, r_{\epsilon}) - \tilde{V}_m(\epsilon, \varphi')(r, r_{\epsilon})||_{C^{2,\alpha}(B_2 - B_1)} \leq c\epsilon ||\varphi - \varphi'||_{C^{2,\alpha}(S^1)}. 
\]

6. The catenoid in \( \mathbb{M}^2 \times \mathbb{R} \)

The catenoid in the space \( \mathbb{M}^2 \times \mathbb{R} \) can be obtained by revolution around the \( x_3 \)-axis, \( \{0, 0\} \times \mathbb{R} \), of an appropriate curve \( \gamma \) (see \[17\]). We consider a vertical geodesic plane containing the origin of \( \mathbb{M}^2 \) and the curve \( \gamma \). Let \( r \) be the Euclidean distance between the point of \( \gamma \) at height \( t \) and the \( x_3 \)-axis: we denote with \( r = r(t) \) a parametrization of \( \gamma \).

The surface obtained by revolution of \( \gamma \) is minimal with respect to the metric \( g_{hyp} \) if and only if \( r = r(t) \) satisfies the following differential equation (see subsection \[12.3\]):

\[
(13) \quad r(t) \frac{\partial^2 r}{\partial t^2} - \left( \frac{\partial r}{\partial t} \right)^2 - (1 - r(t)^4) = 0.
\]

A first integral for this equation is:

\[
(14) \quad \left( \frac{\partial r}{\partial t} \right)^2 = C r^2 - (1 + r^4)
\]

with \( C > 2 \) and constant. By the resolution of equation \( \left( \frac{\partial r}{\partial t} \right)^2 = 0 \), it is easy to prove that the function \( r(t) \) has a minimum value \( r_{min} \) given by:

\[
r_{min} = \sqrt{\frac{C - \sqrt{C^2 - 4}}{2}} = \sqrt{\frac{C/2 + 1}{2}} - \sqrt{\frac{C/2 - 1}{2}} < 1.
\]
Since we assume $C = \frac{1}{\varepsilon}$, we get
\[ r_{\min} = \sqrt{\frac{C/2 + 1}{2}} - \sqrt{\frac{C/2 - 1}{2}} = \frac{\sqrt{C}}{2} \left( 1 + \frac{1}{C} - 1 + \frac{1}{C} + \mathcal{O} \left( \frac{1}{C^2} \right) \right) = \frac{1}{\sqrt{C}} + \mathcal{O} \left( \frac{1}{C^{3/2}} \right) = \varepsilon^2 + \mathcal{O}(\varepsilon^0). \]

We denote with $C_A$ and $C_B$, respectively, the piece of the catenoid contained in $\mathbb{M}^2 \times \mathbb{R}^+$ and $\mathbb{M}^2 \times \mathbb{R}^-$.

We set
\[ t_\varepsilon = -\varepsilon^2 \ln \varepsilon. \]

We need to find the parametrization of $C_A$ and $C_B$ as graphs on the horizontal plane respectively for $t \in [t_\varepsilon - \varepsilon^2 \ln 2, t_\varepsilon + \varepsilon^2 \ln 2]$ and $t \in [-t_\varepsilon - \varepsilon^2 \ln 2, -t_\varepsilon + \varepsilon^2 \ln 2]$. We start by finding the expression of $r(t)$ for $t$ in the interval specified before.

**Lemma 6.1.** For $\varepsilon > 0$ small enough, we have
\[ r(t) = \varepsilon^2 \cosh \frac{t}{\varepsilon^2} + \mathcal{O}(\varepsilon^6 e^{\frac{t}{\varepsilon^2}}) \]
and
\[ \partial_t r(t) = \sinh \frac{t}{\varepsilon^2} + \mathcal{O}(\varepsilon^4 e^{\frac{t}{\varepsilon^2}}) \]
for $t \in [0, t_\varepsilon + \varepsilon^2 \ln 2]$. Moreover if $t \in [t_\varepsilon - \varepsilon^2 \ln 2, t_\varepsilon + \varepsilon^2 \ln 2]$, we derive
\[ r(t) \in \left[ \frac{1}{4} \varepsilon + c_1 \varepsilon^3, \varepsilon + c_2 \varepsilon^3 \right], \]
\[ \partial_t r(t) \in \left[ \frac{1}{4\varepsilon} - c'_1 \varepsilon, \frac{1}{\varepsilon} - c'_2 \varepsilon \right], \]
for some positive constants $c_1, c_2, c'_1, c'_2$.

**Proof.** We define the function $v(t)$ in such a way that $r(t) = r(0) \cosh v(t)$, with $v(0) = 0$ and $r(0)$ the minimum for $r(t)$. It satisfies
\[ Cr^2(0) - (1 + r^4(0)) = 0, \]
from which
\[ 1 = Cr^2(0) - r(0) \]
Plugging $r(t)$ in (14) and using (15), we have
\[ (\partial_t v)^2 = C - r^{-2}(0)(1 + \cosh^2 v(t)) \]
and under the hypothesis
\[ \frac{t}{\varepsilon^2} \leq v(t) \leq \frac{t}{\varepsilon^2} + 1 \]
we obtain that $(\partial_t v)^2 = C + \mathcal{O}(\varepsilon^4 e^{\frac{t}{\varepsilon^2}})$ and then $v(t) = \sqrt{C}t + \mathcal{O}(\varepsilon^6 e^{\frac{t}{\varepsilon^2}})$. We remark a posteriori that $\frac{t}{\varepsilon^2} \leq v(t) \leq \frac{t}{\varepsilon^2} + 1$ holds for $t \in [0, t_\varepsilon + \varepsilon^2 \ln 2], \varepsilon > 0$ small enough. Since $r(0) = r_{\min} = \varepsilon^2 + \mathcal{O}(\varepsilon^6)$, we get
\[ r(t) = r(0) \cosh v(t) = \varepsilon^2 \cosh \left( \frac{t}{\varepsilon^2} \right) + \mathcal{O}(\varepsilon^6 e^{\frac{t}{\varepsilon^2}}). \]
If $t \in [t_\varepsilon - \varepsilon^2 \ln 2, t_\varepsilon + \varepsilon^2 \ln 2]$, then we easily obtain $r(t) \in \left[ \frac{1}{4} \varepsilon + c_1 \varepsilon^3, \varepsilon + c_2 \varepsilon^3 \right]$, for some positive constants $c_1, c_2$. Using $\partial_t r(t) = \sinh \left( \frac{t}{\varepsilon^2} \right) + \mathcal{O}(\varepsilon^4 e^{\frac{t}{\varepsilon^2}})$, we find $\partial_t r(t) \in \left[ \frac{1}{4\varepsilon} - c'_1 \varepsilon, \frac{1}{\varepsilon} - c'_2 \varepsilon \right]$ for some positive constants $c'_1, c'_2$. \qed

Now we can prove a lemma that gives us the parametrization of the pieces of the catenoid whose height $t$ belongs to a neighbourhood of $t_\varepsilon$ and $-t_\varepsilon$. 
Lemma 6.2. For \( \varepsilon > 0 \) small enough and \( t \in [t_\varepsilon, -\varepsilon^2 \ln 2, t_\varepsilon + \varepsilon^2 \ln 2] \), the surface \( C_t \) can be seen as the graph, over the annulus \( B_{2r_\varepsilon} - B_{r_\varepsilon/2} \), of the function \( W_t(\theta, r) \) which satisfies

\[
W_t(\theta, r) = \varepsilon^2 \ln \frac{2r}{\varepsilon^2} + \mathcal{O}_{C_{\varepsilon}^2}(\varepsilon^3).
\]

Similarly if \( t \in [-t_\varepsilon - \varepsilon^2 \ln 2, -t_\varepsilon + \varepsilon^2 \ln 2] \), the surface \( C_b \) can be seen as the graph over \( B_{2r_\varepsilon} - B_{r_\varepsilon/2} \) of the function

\[
W_b(\theta, r) = -\varepsilon^2 \ln \frac{2r}{\varepsilon^2} + \mathcal{O}_{C_{\varepsilon}^2}(\varepsilon^3).
\]

Proof. The first result easily follows from the hypothesis and equation \((16)\). The second result can be shown by observing that \( C_b \) is the image of \( C_t \) by the reflection with respect to the \( x_3 = 0 \) plane. In other terms, \( W_b(\theta, r) = -W_t(\theta, r) \).

7. A FAMILY OF MINIMAL SURFACES CLOSE TO A CATENOID ON \( S^1 \times [r_\varepsilon, 1] \)

In this section we want to show the existence of minimal graphs in \( \mathbb{M}^2 \times \mathbb{R} \) over the parts of the surfaces \( C_t \) and \( C_b \) (described in the previous section) defined on \( S^1 \times [r_\varepsilon, 1] \subset \mathbb{M}^2 \times \{0\} \) and asymptotic to them. We know that the graph of the function \( u + v \) is minimal, \( u \) being the function whose graph is the catenoid, if and only if \( v \) is a solution of the equation

\[
H_{u+v} = 0
\]

whose expression is given by \((11)\). The explicit expression of \( L_u v \) is

\[
F \left( \frac{1}{\sqrt{A}} \Delta u v + \partial_r \left( \frac{1}{\sqrt{A}} \right) \partial_r v - \frac{1}{A^2} \partial_r u \partial_r (F \partial_r u) \partial_r v - F \partial_r u \partial_r \left( \frac{1}{A^2} \partial_r u \partial_r v \right) \right),
\]

where \( F = (1 - r^2)^2 \),

\[
A = 1 + F \lvert \nabla u \rvert^2 = \frac{(C - 2)r^2}{C r^2 - 1 - r^4}
\]

and

\[
\partial_r u = \pm \frac{1}{\sqrt{C r^2 - 1 - r^4}},
\]

as is easy to obtain using \((14)\). It’s useful to observe that since we assume \( C = \frac{1}{\varepsilon^2} \) and \( r_\varepsilon = \varepsilon/2 \), we have that, for \( r \in [r_\varepsilon, 1] \), \( A = 1 + \mathcal{O}(\varepsilon^2) \), \( \partial_r u = \mathcal{O}(\varepsilon) \),

\[
\partial_r A = \frac{2(C - 4)(-r + r^5)}{(C r^2 - 1 - r^4)^2} = \mathcal{O}(\varepsilon^3)
\]

and

\[
\partial_r^2 u = \pm \frac{(C r - 2 r^3)}{\sqrt{(C r^2 - 1 - r^4)^3}} = \mathcal{O}(1).
\]

Taking into account these estimates, we can conclude that

\[
\tilde{L}_u v := \sqrt{A} \left( \partial_r \left( \frac{1}{\sqrt{A}} \right) \partial_r v - \frac{1}{A^2} \partial_r u \partial_r (F \partial_r u) \partial_r v - F \partial_r u \partial_r \left( \frac{1}{A^2} \partial_r u \partial_r v \right) \right)
= l_1 \partial_r v + l_2 \partial_{rr}^2 v,
\]

where \( l_1, l_2 = \mathcal{O}(\varepsilon) \). Then we can write \( \sqrt{A} L_u v = F (\Delta_0 v + \tilde{L}_u v) \).
We remark that we have already studied the mapping properties of the operator $\Delta_0$ in section 4.

Let $\Sigma_u$ be the graph of the function $u$. Then the graph of a function $v$ over $\Sigma_u$ is minimal if and only if $v$ is a solution of the following equation:

\begin{equation}
\Delta_0 v + L_u v + \sqrt{A} Q_u (v) = 0,
\end{equation}

where $Q_u (\cdot) := Q_u \left( \sqrt{F \nabla, \sqrt{F} \nabla^2} \right)$. Thanks to the observations on the functions $A$ and $\partial_1 u$, we can conclude that $Q_u$ has bounded coefficients if $r \in [r_\varepsilon, 1]$.

Now we consider a function $\varphi \in C^{2,\alpha}(S^1)$ which is even with respect to $\theta$, collinear to $\cos(j(k+1)\theta)$ (for $k \geq 1$ fixed) and such that

\begin{equation}
\| \varphi \|_{C^{2,\alpha}} \leq \kappa \varepsilon^2.
\end{equation}

We define

\[ w_\varphi (\cdot, \cdot) := H_{r_\varepsilon, \varphi} (\cdot, \cdot), \]

where the operator $H_{r_\varepsilon, \varphi}$ has been introduced in Proposition 12.1.

In order to solve equation (21), we look for $v$ of the form $v = w_\varphi + w$, where $w \in C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])$ and $v = \varphi$ on $S^1 \times \{ r_\varepsilon \}$. We can rephrase this problem as a fixed point problem, that is,

\begin{equation}
\theta = S(\varphi, w),
\end{equation}

where the nonlinear mapping $S$ is defined by

\[ S(\varphi, w) := -G_{r_\varepsilon} \left( L_u (w_\varphi + w) + \sqrt{A} Q_u (w_\varphi + w) \right), \]

and where the operator $G_{r_\varepsilon}$ is defined in Proposition 4.2. To prove the existence of a solution for (23) we need the following result, which states that $S(\varphi, \cdot)$ is a contraction mapping.

**Lemma 7.1.** Let $\varphi \in C^{2,\alpha}(S^1)$ be a function satisfying (22) and enjoying the properties given above. There exist some constants $c_\kappa > 0$ and $\varepsilon_\kappa > 0$, such that

\begin{equation}
\| S(\varphi, 0) \|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])} \leq c_\kappa \varepsilon^3
\end{equation}

and, for all $\varepsilon \in (0, \varepsilon_\kappa)$,

\begin{align*}
\| S(\varphi, w_2) - S(\varphi, w_1) \|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])} & \leq \frac{1}{2} \| w_2 - w_1 \|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])}, \\
\| S(\varphi, w) - S(\varphi_1, w) \|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])} & \leq c \| \varphi - \varphi_1 \|_{C^{2,\alpha}(S^1)},
\end{align*}

where $c$ is a positive constant, for all $w_1, w_2 \in C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])$ such that $\| w_1 \|_{C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])} \leq 2c_\kappa \varepsilon^4$ and for all boundary data $\varphi_1, \varphi_2 \in C^{2,\alpha}(S^1)$ enjoying the same properties as $\varphi$.

**Proof.** We know from Proposition 4.2 that $\| G_{r_\varepsilon} (f) \|_{C^{2,\alpha}} \leq c \| f \|_{C^{0,\alpha}}$. Then

\begin{align*}
\| S(\varphi, 0) \|_{C^{2,\alpha}} & \leq c \| L_u w_\varphi + \sqrt{A} Q_u (w_\varphi) \|_{C^{0,\alpha}} \\
& \leq c \left( \| L_u w_\varphi \|_{C^{0,\alpha}} + \| Q_u (w_\varphi) \|_{C^{0,\alpha}} \right).
\end{align*}

Here we have used the fact that $A = 1 + O(\varepsilon^2)$.

So we need to find the estimates of each summand. We recall that $\| \varphi \|_{C^{2,\alpha}} \leq \kappa \varepsilon$. Thanks to Proposition 12.1 we get that

\[ \| w_\varphi \|_{C^{2,\alpha}} \leq c \| \varphi \|_{C^{2,\alpha}(S^1)} \leq c_\kappa \varepsilon^2. \]
We use (20) for finding the estimate of $\tilde{L}_u w_\varphi$. We obtain
\[ \|\tilde{L}_u w_\varphi\|_{C^{0,\alpha}} \leq c\varepsilon \|w_\varphi\|_{C^{2,\alpha}} \leq c_\kappa \varepsilon^3. \]
The last term is estimated by observing that
\[ \|Q_u (w_\varphi)\|_{C^{0,\alpha}} \leq c\|w_\varphi\|_{C^{2,\alpha}}^2 \leq c_\kappa \varepsilon^4. \]
Putting together all these estimates we get
\[ \|S(\varphi, 0)\|_{C^{2,\alpha}} \leq c_\kappa \varepsilon^3. \]

As for the second estimate, we observe that
\[
S(\varphi, w_2) - S(\varphi, w_1) = -G_{r_s} \left( \tilde{L}_u (w_\varphi + w_2) + \sqrt{A}Q_u (w_\varphi + w_2) \right) + G_{r_s} \left( \tilde{L}_u (w_\varphi + w_1) + \sqrt{A}Q_u (w_\varphi + w_1) \right).
\]
Consequently
\[
\|S(\varphi, w_2) - S(\varphi, w_1)\|_{C^{2,\alpha}} \leq c\|\tilde{L}_u (w_\varphi + w_2) - \tilde{L}_u (w_\varphi + w_1)\|_{C^{0,\alpha}}
+ c\|\sqrt{A}Q_u (w_\varphi + w_2) - \sqrt{A}Q_u (w_\varphi + w_1)\|_{C^{0,\alpha}}
\leq c (\|\tilde{L}_u (w_2 - w_1)\|_{C^{0,\alpha}} + \|Q_u (w_\varphi + w_2) - Q_u (w_\varphi + w_1)\|_{C^{0,\alpha}}) .
\]

We observe that from the considerations above it follows that
\[ \|\tilde{L}_u (w_2 - w_1)\|_{C^{0,\alpha}} \leq c\varepsilon \|w_2 - w_1\|_{C^{2,\alpha}} \]
and
\[ \|Q_u (w_\varphi + w_2) - Q_u (w_\varphi + w_1)\|_{C^{0,\alpha}} \leq c\|w_2 - w_1\|_{C^{2,\alpha}} \|w_\varphi\|_{C^{2,\alpha}} \]
\[ \leq c_\kappa \varepsilon \|w_2 - w_1\|_{C^{2,\alpha}} . \]

Then
\[ \|S(\varphi, w_2) - S(\varphi, w_1)\|_{C^{2,\alpha}} \leq c\varepsilon \|w_2 - w_1\|_{C^{2,\alpha}} . \]

To show the third estimate we observe that
\[
\|S(\varphi_2, w) - S(\varphi_1, w)\|_{C^{2,\alpha}}
\leq c (\|\tilde{L}_u (w_\varphi_2 - w_\varphi_1)\|_{C^{0,\alpha}} + \|Q_u (w_\varphi_2 + w) - Q_u (w_\varphi_1 + w)\|_{C^{0,\alpha}})
\leq c \varepsilon \|\varphi_2 - \varphi_1\|_{C^{2,\alpha}(S^1)} + \|w\|_{C^{2,\alpha}} \|\varphi_2 - \varphi_1\|_{C^{2,\alpha}(S^1)}
\leq c \varepsilon \|\varphi_2 - \varphi_1\|_{C^{2,\alpha}(S^1)} .
\]

\[ \square \]

**Theorem 7.2.** Let $B := \{ w \in C^{2,\alpha}(S^1 \times [r_\varepsilon, 1]) : \|w\|_{C^{2,\alpha}} \leq 2c_\kappa \varepsilon^3 \}$. Then the nonlinear mapping $S(\varphi, \cdot)$ defined above has a unique fixed point $v$ in $B$.

**Proof:** The previous lemma shows that, if $\varepsilon$ is chosen small enough, the nonlinear mapping $S(\varphi, \cdot)$ is a contraction mapping from the ball $B$ of radius $2c_\kappa \varepsilon^3$ in $C^{2,\alpha}(S^1 \times [r_\varepsilon, 1])$ into itself. This value follows from the estimate of the norm of $S(\varphi, 0)$. Consequently, thanks to the Schauder fixed point theorem, $S(\varphi, \cdot)$ has a unique fixed point $v$ in this ball. \[ \square \]
We have proved the existence of a minimal surface with respect to the metric \( g_{hyp} \), \( S_t(\varphi) \), which is close to the piece of catenoid \( C_t \) introduced in section 6 and close to its boundary is a graph over the annulus \( B_{2r_e} - B_{r_e} \) of the function

\[
\tilde{U}_t(\theta, r) = \varepsilon^2 \ln \frac{2r}{\varepsilon^2} + \mathcal{H}_{r_e \varphi}(\theta, r) + \tilde{V}_t(\theta, r),
\]

with \( \| \tilde{V}_t \|_{C^{2,\alpha}} \leq c\varepsilon^2 \). From the properties of the extension operator \( \mathcal{H}_{r_e \varphi} \) (see Proposition 12.1 and Proposition 12.2) we can see that \( S_t(\varphi) \) is asymptotic to \( C_t \) if \( r \) tends to 1 and it is embedded in \( \mathbb{M}^2 \times \mathbb{R} \).

The function \( \tilde{V}_t \) depends nonlinearity on \( \varepsilon, \varphi \). Furthermore it satisfies

\[
\| \tilde{V}_t(\varepsilon, \varphi)(\cdot, r \cdot) - \tilde{V}_t(\varepsilon, \varphi')(\cdot, r \cdot) \|_{C^{2,\alpha}(B_2 - B_1)} \leq c_\varepsilon \| \varphi - \varphi' \|_{C^{2,\alpha}(S^1)}.
\]

This estimate follows from Lemma 7.1.

Now it is easy to show the existence of a minimal surface \( S_b(\varphi) \), which is close to the part of the catenoid denoted by \( C_b \) introduced in section 6 and close to its boundary is a graph over the annulus \( B_{2r_e} - B_{r_e} \). We start observing that \( C_b \) can be obtained by reflection of \( C_t \) with respect to the \( x_3 = 0 \) plane. So we can define \( S_b(\varphi) \) as the image of \( S_t(\varphi) \) by the composition of a rotation by an angle \( \frac{\pi}{k+1} \) about the \( x_3 \)-axis and the reflection with respect to the horizontal plane. This choice (in particular the apparently unnecessary rotation) is indispensable to assure that the surface we will construct by the gluing procedure in section 11 has the same properties of symmetry as the Costa-Hoffman-Meeks surface. See subsection 9.1 for more information.

It is clear that \( S_b(\varphi) \) is the graph over the annulus \( B_{2r_e} - B_{r_e} \) of the function

\[
\tilde{U}_b(\theta, r) = -\tilde{U}_t \left( \theta - \frac{\pi}{k+1}, r \right).
\]

8. The Relation Between the Mean Curvatures of a Surface in \( \mathbb{D}^2 \times \mathbb{R} \) with Respect to Two Different Metrics

In this section we want to express the mean curvature \( H_{hyp} \) of a surface in \( \mathbb{D}^2 \times \mathbb{R} \) with respect to the metric \( g_{hyp} \) in terms of the mean curvature \( H_e \) of the same surface with respect to the Euclidean metric \( g_0 \).

We recall that, if \( x_1, x_2 \) denote the coordinates in \( \mathbb{D}^2 \) and \( x_3 \) the coordinate in \( \mathbb{R} \), then

\[
g_{hyp} = \frac{dx_1^2 + dx_2^2}{F} + dx_3^2,
\]

where \( F = (1 - x_1^2 - x_2^2)^2 = (1 - r^2)^2 \)

and

\[
g_0 = dx_1^2 + dx_2^2 + dx_3^2.
\]

If \( N_{hyp} \) denotes the normal vector to a surface \( \Sigma \) with respect to the metric \( g_{hyp} \), then its mean curvature with respect to the same metric is given by

\[
H_{hyp}(\Sigma) := -\frac{1}{2} \text{trace} \left( X \to [\nabla_X N_{hyp}]^T \right),
\]

where \([\cdot]^T\) denotes the projection on the tangent bundle \( T\Sigma \) and \( \nabla \) is the Riemannian connection relative to \( g_{hyp} \). The mean curvature of \( \Sigma \) with respect to \( g_0 \), denoted by \( H_e(\Sigma) \), is given by

\[
H_e(\Sigma) := -\frac{1}{2} \text{trace} \left( X \to [\nabla_X N_e]^T \right),
\]
where $N_e$ denotes the normal vector to $\Sigma$ with respect to the metric $g_0$ and $\nabla$ is the flat Riemannian connection.

The Christoffel symbols, $\Gamma^k_{ij}$, associated to the metric $g_{hyp}$ all vanish except

$$
\Gamma^1_{11} = \Gamma^2_{21} = \Gamma^2_{12} = -\Gamma^1_{22} = \frac{2x_1}{\sqrt{F}},
$$

$$
\Gamma^1_{12} = \Gamma^2_{22} = \Gamma^1_{21} = -\Gamma^2_{11} = \frac{2x_2}{\sqrt{F}}.
$$

Let $\partial_1 = \frac{\partial}{\partial x_1}, \partial_2 = \frac{\partial}{\partial x_2}, \partial_3 = \frac{\partial}{\partial x_3}$ be the elements of a basis of the tangent space. Now, if $X = \sum_i X^i \partial_i$ and $Y = \sum_j Y^j \partial_j$ are two tangent vector fields, the expression of the covariant derivative in $(\mathbb{D}^2 \times \mathbb{R}, g_{hyp})$ is given by

$$
\nabla_X Y = \sum_k \left( X(Y^k) + \sum_{i,j} X^i Y^j \Gamma^k_{ij} \right) \partial_k.
$$

It is clear that

$$
\nabla_X Y = \nabla_X Y + \sum_{k=1}^{2} \sum_{i,j} X^i Y^j \Gamma^k_{ij} \partial_k.
$$

We suppose that $N_{hyp} = (N^1, N^2, N^3)$. From (26) we get the relation

$$
\nabla_X N_{hyp} = \nabla_X N_{hyp} + \sum_{k=1}^{2} \sum_{i,j} X^i N^j \Gamma^k_{ij} \partial_k.
$$

We start by evaluating the term $\nabla_X N_{hyp}$. We observe that the normal vector $N_e = (N_1, N_2, N_3)$ to $\Sigma$ with respect to the metric $g_0$ does not coincide with $N_{hyp}$. But it is clear that

$$
N_{hyp} = (N^1, N^2, N^3) = (\sqrt{F} N_1, \sqrt{F} N_2, N_3).
$$

We observe that

$$
\nabla_X N_{hyp} = \sum_{k=1}^{3} X(N^k) \partial_k = X(\sqrt{F} N_1) \partial_1 + X(\sqrt{F} N_2) \partial_2 + X(N_3) \partial_3.
$$

We can write $X(\sqrt{F} N_k) = (1 - r^2) X(N_k) - X(r^2) N_k$, for $k = 1, 2$. Since

$$
X(N_k) = \sum_{l=1}^{3} X^l \partial_{x_l} N_k \quad \text{and} \quad X(r^2) = 2x_1 X^1 + 2x_2 X^2,
$$

it follows that

$$
X(\sqrt{F} N_k) = X(N_k) - (2x_1 X^1 + 2x_2 X^2) \ N_k - r^2 \left( \sum_{l=1}^{3} X^l \partial_{x_l} N_k \right),
$$

for $k = 1, 2$. We can conclude that $\nabla_X N_{hyp} = \sum_k X(N^k) \partial_k$ is given by

$$
\sum_{k=1}^{3} X(N_k) \partial_k - (2x_1 X^1 + 2x_2 X^2) \sum_{k=1}^{2} N_k \partial_k - r^2 \left( \sum_{l=1}^{3} X^l \partial_{x_l} N_k \right) \partial_k.
$$
Inserting this equality into \((20)\) and observing that \(\sum_{k=1}^{3} X(N_k)\partial_k = \nabla X N_e\), we obtain
\[
\nabla X N_{hyp} = \nabla X N_e - (2x_1X^1 + 2x_2X^2) \sum_{k=1}^{2} N_k \partial_k - r^2 \sum_{k=1}^{2} \left( \sum_{i=1}^{3} X^i \partial x_i N_k \right) \partial_k.
\]
Replacing this result into \((27)\) we find the following expression of \(\nabla X N_{hyp}\), which we will consider to compute the trace. We will assume \(X\) to be a vector field tangent to \(\Sigma\). Then
\[
(28) \quad \nabla X N_{hyp} = \nabla X N_e - (2x_1X^1 + 2x_2X^2) \sum_{k=1}^{2} N_k \partial_k - r^2 \sum_{k=1}^{2} \left( \sum_{i=1}^{3} X^i \partial x_i N_k \right) \partial_k + \sum_{k=1}^{2} \sum_{i,j=1}^{3} X^i N^j \Gamma^k_{ij} \partial_k.
\]
We start to study the second summand. \((2x_1X^1 + 2x_2X^2) \sum_{k=1}^{2} N_k \partial_k\) is the vector whose components with respect to the basis \((\partial_1, \partial_2, \partial_3)\) are given by
\[
\begin{bmatrix}
2x_1 N_1 \\
2x_2 N_1 \\
0
\end{bmatrix}
\begin{bmatrix}
2x_1 N_2 \\
2x_2 N_2 \\
0
\end{bmatrix}
\begin{bmatrix}
X^1 \\
X^2 \\
X^3
\end{bmatrix}.
\]
So the trace of the mapping \(\sum_{i=1}^{3} X^i \partial_i \rightarrow \left( (2x_1X^1 + 2x_2X^2) \sum_{k=1}^{2} N_k \partial_k \right)^T\) equals \(2O(x_1 N_1 + x_2 N_2)\).
The components of the vector
\[
\sum_{k=1}^{2} \left( \sum_{i=1}^{3} X^i \partial x_i N_k \right) \partial_k
\]
with respect to the basis \((\partial_1, \partial_2, \partial_3)\) are given by
\[
\begin{bmatrix}
\partial x_1 N_1 \\
\partial x_2 N_1 \\
0
\end{bmatrix}
\begin{bmatrix}
\partial x_1 N_2 \\
\partial x_2 N_2 \\
0
\end{bmatrix}
\begin{bmatrix}
X^1 \\
X^2 \\
X^3
\end{bmatrix}.
\]
So the trace of the mapping
\[
\sum_{i=1}^{3} X^i \partial_i \rightarrow r^2 \left[ \sum_{k=1}^{2} \left( \sum_{i=1}^{3} X^i \partial x_i N_k \right) \partial_k \right]^T
\]
equals \(O \left( r^2 (\partial x_1 N_1 + \partial x_2 N_2) \right)\).
As for the last term of \((28)\), we can state that \(\sum_{k=1}^{2} \sum_{i,j} X^i N^j \Gamma^k_{ij} \partial_k\) is the vector whose components with respect to the basis \((\partial_1, \partial_2, \partial_3)\) are given by
\[
(29) \quad \begin{bmatrix}
\frac{2x_1 N^1}{\sqrt{F}} + \frac{2x_2 N^2}{\sqrt{F}} \\
\frac{2x_1 N^1}{\sqrt{F}} + \frac{2x_2 N^2}{\sqrt{F}} \\
0
\end{bmatrix}
\begin{bmatrix}
X^1 \\
X^2 \\
X^3
\end{bmatrix}.
\]
Taking into account the equalities \(N^1 = \sqrt{F} N_1\) and \(N^2 = \sqrt{F} N_2\), it is easy to conclude that the trace of the mapping
\[
\sum_{i} X^i \partial_i \rightarrow \left[ \sum_{k=1}^{2} \sum_{i,j} X^i N^j \Gamma^k_{ij} \partial_k \right]^T
\]
equals $4O(x_1N_1 + x_2N_2)$. From the definition of the mean curvatures it is easy to obtain the following relation:

$$H_{hyp}(\Sigma) = H_e(\Sigma) - O(x_1N_1 + x_2N_2) + r^2O(\partial x_1N_1 + \partial x_2N_2).$$

We have proved the following result.

**Proposition 8.1.** Let $S$ be a surface in $\mathbb{D}^2 \times \mathbb{R}$ endowed with the metric $g_{hyp}$. If $H_{hyp}(\cdot)$ denotes the mean curvature with respect to the metric $g_{hyp}$, and if $H_e(\cdot)$ and $(N_1, N_2, N_3)$ denote respectively the mean curvature and the normal vector to $S$ with respect to $g_0$, then

$$H_{hyp}(S) = H_e(S) - O(x_1N_1 + x_2N_2) + r^2O(\partial x_1N_1 + \partial x_2N_2),$$

where $x_1, x_2$ are the Euclidean coordinates on $\mathbb{D}^2$ and $r^2 = x_1^2 + x_2^2$.

In this section we will describe the surface obtained by scaling of $M_k$, the Costa-Hoffman-Meeks surface of genus $k \geq 1$ (see C. Costa [1], [2] and D. Hoffman and W. H. Meeks [3], [4]) and we will study the mapping properties of its Jacobi operator. We denote by $M_{k,\varepsilon}$ the image of $M_k$ by a homothety of ratio $\varepsilon^2$. We will adapt to our situation some of the analytical tools used in [5] to show the existence of a family of minimal surfaces in $\mathbb{R}^3$ close to $M_k$ with one planar end and two slightly bent catenoidal ends by an angle $\xi \in (-\xi_0, \xi_0)$, $\xi_0 > 0$ and small enough. We denote an element of this family by $M_k(\xi)$. Then $M_k(\xi)|_{\xi=0} = M_k$.

#### 9.1. The Costa-Hoffman-Meeks surface

We start by giving a brief description of the surface $M_k$. After suitable rotation and translation, $M_k$ enjoys the following properties.

1. It has one planar end $E_m$ asymptotic to the $x_3 = 0$ plane, one top end $E_t$ and one bottom end $E_b$ that are respectively asymptotic to the upper end and to the lower end of a catenoid with $x_3$-axis of revolution. The planar end $E_m$ is located between the two catenoidal ends.
2. It is invariant under the action of the rotation of angle $\frac{2\pi}{k+1}$ about the $x_3$-axis, under the action of the symmetry with respect to the $x_2 = 0$ plane and under the action of the composition of a rotation of angle $\frac{\pi}{k+1}$ about the $x_3$-axis and the symmetry with respect to the $x_3 = 0$ plane.
3. It intersects the $x_3 = 0$ plane in $k + 1$ straight lines, which intersect themselves at the origin with angles equal to $\frac{\pi}{k+1}$. The intersection of $M_k$ with the plane $x_3 = \text{const} \neq 0$ is a single Jordan curve. The intersection of $M_k$ with the upper half space $x_3 > 0$ (resp. with the lower half space $x_3 < 0$) is topologically an open annulus.

We denote by $X_i$, with $i = t, b, m$, the parametrization of the end $E_i$ and with $X_{i,\varepsilon}$ the parametrization of the corresponding end $E_{i,\varepsilon}$ of $M_{k,\varepsilon}$.

Now we give a local description of the surface $M_{k,\varepsilon}$ near its ends and we introduce coordinates that we will use.

**The planar end.** The planar end $E_{m,\varepsilon}$ of the surface $M_{k,\varepsilon}$ can be parametrized by

$$X_{m,\varepsilon}(x) := \left(\frac{\varepsilon^2 x}{|x|^2}, \varepsilon^2 u_m(x)\right) \in \mathbb{R}^3,$$
where $x \in \bar{B}_{\rho_0}(0) - \{0\} \subset \mathbb{R}^2$. Here $\rho_0 > 0$ is fixed small enough. In the sequel, where necessary, we will consider on $B_{\rho_0}(0)$ also the polar coordinates $(\theta, \rho) \in S^1 \times [0, \rho_0]$. The function $u_m$ satisfies the minimal surface equation, which has the following form:

\begin{equation}
2H_u = \frac{|x|^4}{\varepsilon^2} \text{div} \left( \frac{\nabla u}{1 + |x|^4|\nabla u|^2} \right) = 0.
\end{equation}

It can be shown (see [6]) that the function $u_m$ can be extended at the origin continuously using the Weierstrass representation. In particular we can prove that $u_m \in C^{2,\alpha}(\bar{B}_{\rho_0})$ and $u_m = O_{C^{2,\alpha}}(|x|^{k+1})$, where the expression $O_{C^{2,\alpha}}(g)$ denotes a function that, together with its partial derivatives of order less than or equal to $n + \alpha$, is bounded by a constant times $g$. Furthermore, taking into account the symmetries of the surface, it is possible to show that the function $u_m$, in polar coordinates, has to be collinear to $\cos j(k+1)\theta$, with $j \geq 1$ and odd.

If we linearize in $u = 0$ the nonlinear equation (33), we obtain the expression of an operator which is, up to a multiplication by $\varepsilon^4$, the Jacobi operator about the plane, that is, $\mathbb{L}_{\mathbb{R}^2} = |x|^4 \Delta_0$. To be more precise, the linearization of (33) gives

\begin{equation}
L_u v = \frac{|x|^4}{\varepsilon^2} \text{div} \left( \frac{\nabla v}{1 + |x|^4|\nabla u|^2} - |x|^4 \nabla u \frac{\nabla u \cdot \nabla v}{\sqrt{1 + |x|^4|\nabla u|^2}} \right).
\end{equation}

We will give the expression of $H_{u+v}$, the mean curvature of the graph of the function $u + v$, in terms of the mean curvature of $\Sigma_u$, that is, $H_u$.

Here we will show that

\begin{equation}
2H_{u+v} = 2H_u + L_u v + \frac{|x|^4}{\varepsilon^2} Q_u(|x|^2 \nabla v, |x|^2 \nabla^2 v),
\end{equation}

where $Q_u$ satisfies

\begin{equation*}
Q_u(0,0) = 0, \nabla Q_u(0,0) = 0.
\end{equation*}

To show (35), we start by observing that

\begin{equation}
\frac{1}{\sqrt{1 + |x|^4|\nabla (u+v)|^2}} = \frac{1}{\sqrt{1 + |x|^4|\nabla u|^2}} - |x|^4 \frac{\nabla u \cdot \nabla v}{\sqrt{1 + |x|^4|\nabla u|^2}^3} + Q_{u,1}(v),
\end{equation}

where the function $Q_{u,1}$ satisfies $Q_{u,1}(0) = 0, \nabla Q_{u,1}(0) = 0$. The proof of that is very close to the one that appears in section 3: it’s necessary only to replace $F$ by $|x|^4$. So we can omit some details. Secondly we observe that $2H_{u+v}$ is given by

\begin{align*}
\frac{|x|^4}{\varepsilon^2} \text{div} & \left( \frac{\nabla (u+v)}{\sqrt{1 + |x|^4|\nabla u|^2}} - |x|^4 \nabla (u+v) \frac{\nabla u \cdot \nabla v}{\sqrt{1 + |x|^4|\nabla u|^2}^3} + \nabla (u+v)Q_{u,1}(v) \right) \\
&= 2H_u + \frac{|x|^4}{\varepsilon^2} \text{div} \left( \frac{\nabla v}{\sqrt{1 + |x|^4|\nabla u|^2}} - |x|^4 \nabla u \frac{\nabla u \cdot \nabla v}{\sqrt{1 + |x|^4|\nabla u|^2}^3} \right) \\
&\quad + \frac{|x|^4}{\varepsilon^2} Q_u(|x|^2 \nabla v, |x|^2 \nabla^2 v).
\end{align*}

From this the wanted expression follows.

Since we assume that $\Sigma_u$ is a minimal surface, we will consider $H_u = 0$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Following what we have done in section \[7\] replacing \( F \) by \(|x|^4\) we get:

\[
|\varepsilon|^4 \left( \frac{1}{\varepsilon^2} \left( \Delta_0 w + \sqrt{1 + |\nabla u|^2} (L_w + Q_u (|x|^2 \nabla v, |x|^2 \nabla^2 v)) \right) \right) = 0,
\]

(37)

where \( L_w \) is a second order linear operator with coefficients in \( \mathcal{O}_{C^2}(|x|^{k+1}) \).

It is important to remark that if the function \( v \) satisfies equation (37) with \( u = u_m \), then the graph of the function \( \varepsilon^2 (u_m + v) \) is minimal. Now we are interested in finding the equation which a function \( w \) must satisfy in such a way that the surface parametrized by \( X_{m,\varepsilon} + w e_3 \), that is, the graph of \( w \) over the middle end \( E_{m,\varepsilon} \), is minimal, which is equivalent to requiring that the graph of \( \varepsilon^2 u_m + w \) is minimal. Then we can obtain the wanted equation by replacing \( v \) by \( w/\varepsilon^2 \) in (37).

So we get

\[
|\varepsilon|^4 \Delta_0 w + |\varepsilon|^4 \frac{1}{\varepsilon^2} \left( \frac{1}{\varepsilon^2} L_w + Q_u \left( \frac{|x|^2}{\varepsilon^2} \nabla w, \frac{|x|^2}{\varepsilon^2} \nabla^2 w \right) \right) = 0.
\]

(38)

If we set \( Q_{\varepsilon,u} (\cdot) := \frac{|\varepsilon|^4}{\varepsilon^4} \sqrt{1 + |x|^4 |\nabla u|^2} Q_u \left( \frac{|x|^2}{\varepsilon^2} \nabla w, \frac{|x|^2}{\varepsilon^2} \nabla^2 w \right) \) to simplify the notation, we can write this equation in the following way:

\[
\frac{|x|^4}{\varepsilon^4} \Delta_0 w + \frac{|x|^4}{\varepsilon^4} \sqrt{1 + |x|^4 |\nabla u|^2} L_w w + Q_{\varepsilon,u} (w) = 0.
\]

(39)

The catenoidal ends. We denote by \( X_c \) the parametrization of the standard catenoid \( C \) whose axis of revolution is the \( x_3 \)-axis. Its expression is

\[
X_c(s, \theta) := (\cosh s \cos \theta, \cosh s \sin \theta, s) \in \mathbb{R}^3,
\]

where \((s, \theta) \in \mathbb{R} \times S^1\). The unit normal vector field about \( C \) is given by

\[
n_c(s, \theta) := \frac{1}{\cosh s} (\cos \theta, \sin \theta, - \sinh s).
\]

The catenoid \( C \) may be divided into two pieces, denoted by \( C_\pm \), which are defined as the image by \( X_c \) of \( \mathbb{R} \times S^1 \). For any \( \varepsilon > 0 \), we define the catenoid \( C_{\varepsilon} \) as the image of \( C \) by a homothety of ratio \( \varepsilon^2 \). We denote by \( X_{c,\varepsilon} := \varepsilon^2 X_c \) its parametrization. Of course, by this transformation, two surfaces correspond to \( C_\pm \). We denote them by \( C_{\varepsilon,\pm} \).

Up to some dilation, we can assume that the two ends \( E_{t,\varepsilon} \) and \( E_{b,\varepsilon} \) of \( M_{k,\varepsilon} \) are asymptotic to some translated copy of the catenoid parametrized by \( X_{c,\varepsilon} \) in the vertical direction. Therefore, \( E_{t,\varepsilon} \) and \( E_{b,\varepsilon} \) can be parametrized, respectively, by

\[
X_{t,\varepsilon} := X_{c,\varepsilon} + w_t n_c + \sigma_{t,\varepsilon} e_3
\]

for \((s, \theta) \in (s_0, \infty) \times S^1\),

(40)

\[
X_{b,\varepsilon} := X_{c,\varepsilon} - w_b n_c - \sigma_{b,\varepsilon} e_3
\]

for \((s, \theta) \in (-\infty, -s_0) \times S^1\), where \( \sigma_{t,\varepsilon}, \sigma_{b,\varepsilon} \in \mathbb{R} \) and the functions \( w_t, w_b \) tend exponentially fast to 0 as \( s \) goes to \( \pm \infty \), reflecting the fact that the \( \sigma \)s are asymptotic to a catenoidal end. Furthermore, taking into account the symmetries of the surface, it is easy to show that the functions \( w_t, w_b \), in terms of the \((s, \theta)\) coordinates, have to be collinear to \( \cos(j(k+1)\theta) \), with \( j \in \mathbb{N} \) and must satisfy \( w_b(s, \theta) = -w_t(s, \theta - \frac{\pi}{k+1}) \). Furthermore we have \( \sigma_{t,\varepsilon} = \sigma_{b,\varepsilon} \).

In section 3 of [12] the expression of the mean curvature operator of a surface close to a scaled standard catenoid is given. We can adapt this result to our situation.
We obtain that the surface parametrized by $X_{c,\varepsilon} + w_n$ is minimal if and only if the function $w$ satisfies the minimal surface equation

$$\frac{1}{\varepsilon^4} L_C w + Q_\varepsilon(w) = 0,$$

$L_C$ being the Jacobi operator about the catenoid, i.e.

$$L_C w = \frac{1}{\cosh^2 s} \left( \partial_s^2 w + \partial_{\theta\theta}^2 w + \frac{2w}{\cosh^2 s} \right),$$

and

$$Q_\varepsilon(w) = \frac{1}{\varepsilon^2 \cosh^2 s} Q_2 \left( \frac{w}{\varepsilon^2 \cosh s} \right) + \frac{1}{\varepsilon^2 \cosh s} Q_3 \varepsilon \left( \frac{w}{\varepsilon^2 \cosh s} \right).$$

Here $Q_2, Q_3$ are nonlinear second order differential operators which are bounded in $C^k(\mathbb{R} \times S^1)$, for every $k$, and satisfy $Q_2(0) = Q_3(0) = 0$, $\nabla Q_2(0) = \nabla Q_3(0) = 0$, $\nabla^2 Q_3(0) = 0$ together with:

$$\|Q_j(v_2) - Q_j(v_1)\|_{C^{0,\alpha}([s,s+1] \times S^1)} \
\leq c \left( \sup_{i=1,2} \|v_i\|_{C^{2,\alpha}([s,s+1] \times S^1)} \right)^j \|v_2 - v_1\|_{C^{2,\alpha}([s,s+1] \times S^1)}$$

for all $s \in \mathbb{R}$ and all $v_1, v_2$ such that $\|v_i\|_{C^{2,\alpha}([s,s+1] \times S^1)} \leq 1$. The constant $c > 0$ does not depend on $s$.

For all $\rho < \rho_0$ and $s > s_0$, we define

$$M_{k,\varepsilon}(s, \rho) := M_{k,\varepsilon} - \left[ X_{c,\varepsilon}(s, \infty) \times S^1 \cup X_{b,\varepsilon}(\infty, -s) \times S^1 \cup X_{m,\varepsilon}(B_{\rho}(0)) \right].$$

The parametrizations of the three ends of $M_{k,\varepsilon}$ induce a decomposition of $M_{k,\varepsilon}$ into slightly overlapping components: a compact piece $M_{k,\varepsilon}(s_0 + 1, \rho_0/2)$ and three noncompact pieces $X_{c,\varepsilon}(s_0, \infty) \times S^1$, $X_{b,\varepsilon}(\infty, -s_0) \times S^1$ and $X_{m,\varepsilon}(B_{\rho_0}(0))$.

We define a weighted space of functions on $M_{k,\varepsilon}$.

**Definition 9.1.** Given $\ell \in \mathbb{N}$, $\alpha \in (0, 1)$ and $\delta \in \mathbb{R}$, the space $C^{\ell,\alpha}_\delta(M_{k,\varepsilon})$ is defined to be the space of functions in $C^{\ell,\alpha}_\delta(M_{k,\varepsilon})$ for which the following norm is finite:

$$\|w\|_{C^{\ell,\alpha}_\delta(M_{k,\varepsilon})} := \|w\|_{C^{\ell,\alpha}(M_{k,\varepsilon}(s_0, \rho_0/2))} + \|w \circ X_{m,\varepsilon}\|_{C^{\ell,\alpha}(B_{\rho_0}(0))} + \|w \circ X_{c,\varepsilon}\|_{C^{\ell,\alpha}((s_0, \infty) \times S^1)} + \|w \circ X_{b,\varepsilon}\|_{C^{\ell,\alpha}((-\infty, -s_0) \times S^1)},$$

where

$$\|f\|_{C^{\ell,\alpha}_\delta((s_0, \infty) \times S^1)} = \sup_{s \geq s_0} \left( e^{-\delta s} \|f\|_{C^{\ell,\alpha}([s, s+1] \times S^1)} \right),$$

$$\|f\|_{C^{\ell,\alpha}_\delta((-\infty, -s_0) \times S^1)} = \sup_{s \leq -s_0} \left( e^{\delta s} \|f\|_{C^{\ell,\alpha}([-1, s] \times S^1)} \right)$$

and which are invariant under the action of the symmetry with respect to the $x_2 = 0$ plane, that is, $w(p) = w(\tilde{p})$ for all $p \in M_{k,\varepsilon}$, where $\tilde{p} := (x_1, -x_2, x_3)$ if $p = (x_1, x_2, x_3)$, invariant with respect to a rotation of angle $\frac{2\pi}{k+1}$ about the $x_3$-axis and to the composition of a rotation of angle $\frac{\pi}{k+1}$ about the $x_3$-axis and the symmetry with respect to the $x_3 = 0$ plane.

We remark that there is no weight on the middle end. In fact we compactify this end and we consider a weighted space of functions defined on a two-ended surface. We will perturb the surface $M_{k,\varepsilon}$ by the normal graph of a function $u \in C^{2,\alpha}_\delta(M_{k,\varepsilon})$. 

9.2. The Jacobi operator. The Jacobi operator about $M_{k,\varepsilon}$ is

$$\mathbb{L}_{M_{k,\varepsilon}} := \Delta_{M_{k,\varepsilon}} + |A_{M_{k,\varepsilon}}|^2,$$

where $|A_{M_{k,\varepsilon}}|$ is the norm of the second fundamental form on $M_{k,\varepsilon}$.

In the parametrization of the ends introduced above, the volume forms $d\text{vol}_{M_{k,\varepsilon}}$ can be written as $\gamma_1 \, ds \, d\theta$ and $\gamma_2 \, ds \, d\theta$ near the catenoidal type ends and as $\gamma_m \, dx_1 \, dx_2$ near the middle end. Now we can define globally on $M_{k,\varepsilon}$ a smooth function

$$\gamma : M_{k,\varepsilon} \rightarrow [0, \infty)$$

that is identically equal to $\varepsilon^4$ on $M_{k,\varepsilon}(s_0 - 1, 2\rho_0)$ and equal to $\gamma_t$ (resp. $\gamma_b$, $\gamma_m$) on the end $E_{t,\varepsilon}$ (resp. $E_{b,\varepsilon}$, $E_{m,\varepsilon}$). They are defined in such a way that on $X_{t,\varepsilon}((s_0, \infty) \times S^1)$ and on $X_{b,\varepsilon}((-\infty, -s_0) \times S^1)$ we have

$$\gamma \circ X_{t,\varepsilon}(s, \theta) \sim \varepsilon^4 \cosh^2 s \quad \text{and} \quad \gamma \circ X_{b,\varepsilon}(s, \theta) \sim \varepsilon^4 \cosh^2 s.$$

Finally on $X_{m,\varepsilon}(B_{\rho_0})$, we have

$$\gamma \circ X_{m,\varepsilon}(x) \sim \frac{\varepsilon^4}{|x|^4}.$$

It is possible to check that

$$\mathcal{L}_{\varepsilon,\delta} : C_\delta^{2,\alpha}(M_{k,\varepsilon}) \rightarrow C_\delta^{0,\alpha}(M_{k,\varepsilon})$$

$$w \mapsto \gamma \mathbb{L}_{M_{k,\varepsilon}}(w)$$

is a bounded linear operator. The subscript $\delta$ is meant to keep track of the weighted space over which the Jacobi operator is acting. Observe that the function $\gamma$ is here to counterbalance the effect of the conformal factor $\frac{1}{\sqrt{|\partial M_{k,\varepsilon}}|}$ in the expression of the Laplacian in the coordinates we use to parametrize the ends of the surface $M_{k,\varepsilon}$. This is precisely what is needed to have the operator defined from the space $C_\delta^{2,\alpha}(M_{k,\varepsilon})$ into the target space $C_\delta^{0,\alpha}(M_{k,\varepsilon})$.

To have a better grasp of what is going on, let us linearize the nonlinear equation (42) at $w = 0$. We get the expression of the Jacobi operator about the scaled catenoid $C_\varepsilon$:

$$\mathbb{L}_{C_\varepsilon} := \frac{1}{\varepsilon^4 \cosh^2 s} \left( \partial_s^2 + \partial_\theta^2 + \frac{2}{\cosh^2 s} \right).$$

We can observe that the operator $\cosh^2 s \mathbb{L}_{C_\varepsilon}$ maps the space $(\cosh s)^\delta C^{2,\alpha}((s_0, +\infty) \times S^1)$ into the space $(\cosh s)^\delta C^{0,\alpha}((s_0, +\infty) \times S^1)$.

Similarly, if we linearize the nonlinear equation (33) at $u = 0$, we obtain (see (3) with $u = 0$), up to a multiplication by $1/\varepsilon^4$, the expression of the Jacobi operator about the plane:

$$\frac{1}{\varepsilon^4} \mathbb{L}_{\mathbb{R}^2} := \frac{|x|^4}{\varepsilon^4} \Delta_0.$$ 

Again, the operator $\gamma \frac{1}{\varepsilon^4} \mathbb{L}_{\mathbb{R}^2} = \Delta_0$ clearly maps the space $C^{2,\alpha}(\mathbb{B}_{\rho_0})$ into the space $C^{0,\alpha}(\mathbb{B}_{\rho_0})$. Now, the function $\gamma$ plays, for the ends of the surface $M_{k,\varepsilon}$, the role played by the function $\cosh^2 s$ for the ends of the standard catenoid and the role played by the function $|x|^{-4}$ for the plane. Since the Jacobi operator about $M_{k,\varepsilon}$ is asymptotic to $\frac{1}{\varepsilon^4} \mathbb{L}_{\mathbb{R}^2}$ at $E_{m,\varepsilon}$ and is asymptotic to $\mathbb{L}_{C_\varepsilon}$ at $E_{t,\varepsilon}$ and $E_{b,\varepsilon}$, we conclude that the operator $\mathcal{L}_{\varepsilon,\delta}$ maps $C_\delta^{2,\alpha}(M_{k,\varepsilon})$ into $C_\delta^{0,\alpha}(M_{k,\varepsilon})$.

Now we recall the notion of nondegeneracy introduced in [6].
Definition 9.2. The surface $M_{k,\varepsilon}$ is said to be nondegenerate if $L_{\varepsilon,\delta}$ is injective for all $\delta < -1$.

It is useful to observe that a duality argument in the weighted Lebesgue spaces implies that

$$
(L_{\varepsilon,\delta} \text{ is injective}) \iff (L_{\varepsilon,-\delta} \text{ is surjective})
$$

if $\delta \notin \mathbb{Z}$. See [13] and [10] for more details.

The nondegeneracy of $M_{k,\varepsilon}$ is related to the mapping properties of $L_{\varepsilon,\delta}$ and to the kernel of this operator. From the observations made above, it follows that at the catenoidal type ends the Jacobi operators of $M_{k,\varepsilon}$ and $M_k$ are respectively asymptotic to $L_C$ and $L_R$, which coincide up to a multiplication by $\varepsilon^4$; at the middle end they are respectively asymptotic to $\frac{1}{\varepsilon}L_{\mathbb{R}^2}$ and $L_{\mathbb{R}^2}$. So we could transpose some of the results about the surface $M_k(0)$ contained in [6] related to the study of its mean curvature operator, to the surface $M_{k,\varepsilon}$, including nondegeneracy. The only difference is that here we work with spaces of functions invariant with respect to all of the symmetries of $M_k$.

The Jacobi fields. It is known that a smooth one-parameter group of isometries containing the identity generates a Jacobi field, that is, a solution of the equation $L_{M_{k,\varepsilon}}u = 0$. The Jacobi fields of this type, which are invariant with respect to the mirror symmetry by the $x_2 = 0$ plane, the rotation by $\frac{2\pi}{k+1}$ about the $x_3$-axis, the composition of the rotation by $\frac{\pi}{k+1}$ about the $x_3$-axis and the mirror symmetry with respect to the $x_3 = 0$ plane, are generated by dilations. Of course the Jacobi equation has other solutions which are not taken into account because they are not invariant under the action of the symmetries listed above. See [6] for details.

The Killing vector field $\Xi(p) = p$, which is associated to the one-parameter group of dilations, generates the Jacobi field

$$
\Phi(p) := n(p) \cdot p.
$$

It is clear that $\Phi(p)$ grows linearly and so it is not bounded.

With this notation, we define the deficiency space

$$
\mathcal{D} := \text{Span}\{\chi_t \Phi, \chi_b \Phi\},
$$

where $\chi_t$ is a cutoff function that is identically equal to 1 on $X_{k,\varepsilon}((s_0+1, +\infty) \times S^1)$, identically equal to 0 on $M_{k,\varepsilon} - X_{k,\varepsilon}((s_0, +\infty) \times S^1)$ and that is invariant under the action of the symmetries listed above. The cutoff function $\chi_b$ is obtained from $\chi_t$ by using the symmetries. Clearly, if $\delta < 0$, then

$$
\tilde{L}_{\varepsilon,\delta} : C^{2,\alpha} \otimes \mathcal{D} \quad \mapsto \quad C^{0,\alpha} \otimes \gamma L_{M_{k,\varepsilon}} w
$$

is a bounded linear operator. Thanks to a result of S. Nayatani about the dimension of the kernel of the Jacobi operator of $M_k$, shown in [13] and extended in [10], we can state that there is not any bounded Jacobi field which is invariant with respect to the symmetries of $M_{k,\varepsilon}$.

So we get the following result about the operator $L_{\varepsilon,\delta}$.

Proposition 9.3. We choose $\delta \in (1/2)$. Then the operator $L_{\varepsilon,\delta}$ is surjective. Moreover, there exists $G_{\varepsilon,\delta}$, a right inverse for $L_{\varepsilon,\delta}$ whose norm is bounded.
Proposition 9.4. We choose \( \delta \in (-2, -1) \). Then the operator \( \tilde{L}_{\varepsilon, \delta} \) is surjective.

10. An infinite dimensional family of minimal surfaces which are close to a compact part of a scaled Costa-Hoffman-Meeks type surface in \( \mathbb{R}^2 \times \mathbb{R} \)

We recall that in section 8, we found that the mean curvature with respect to the metric \( g_{\text{hyp}} \) of a surface \( S \) in \( \mathbb{M}^2 \times \mathbb{R} \) can be expressed in terms of the Euclidean mean curvature of \( S \) and the components of the normal vector to the same surface with respect to the flat metric \( g_0 \).

In this section, we will apply this result to prove the existence of a family of minimal surfaces close to a scaled Costa-Hoffman-Meeks type surface in \( \mathbb{M}^2 \times \mathbb{R} \).

Lemma 10.1. There exists \( \varepsilon_0 > 0 \) such that, for all \( \varepsilon \in (0, \varepsilon_0) \), an annular part of the ends \( E_{t, \varepsilon} \), \( E_{b, \varepsilon} \), and \( E_{m, \varepsilon} \) of \( M_{k, \varepsilon} \) can be written as vertical graphs over the annulus \( B_{2r_\varepsilon} - B_{r_\varepsilon/2} \) of the functions

\[
Z_t(\theta, r) = \sigma_{t, \varepsilon} + \varepsilon^2 \ln \left( \frac{2r}{\varepsilon^2} \right) + O_{C^2_b}(\varepsilon^3),
\]

\[
Z_b(\theta, r) = -Z_t \left( \theta - \frac{\pi}{k+1}, r \right).
\]

As for the parametrization of the planar end, it satisfies

\[
Z_m(\theta, r) = O_{C^2_b} \left( \frac{r}{\varepsilon^2} \right)^{-\frac{(k+1)}{2}}.
\]

Here \((\theta, r)\) are the polar coordinates in the \( x_3 = 0 \) plane. The functions \( O_{C^2_b}(f) \) are defined in the annulus \( B_{2r_\varepsilon} - B_{r_\varepsilon/2} \) and are bounded in the \( C^2_b \) topology by a constant (independent of \( f \)) multiplied by \( f \), where the partial derivatives are computed with respect to the vector fields \( r \partial_r \) and \( \partial_\theta \).

We set

\[
s_\varepsilon = -\ln \varepsilon, \quad \rho_\varepsilon := 2\varepsilon
\]

and we define \( M^T_{k, \varepsilon} \) to be equal to \( M_{k, \varepsilon} \), from which we have removed the image of \((s_\varepsilon, +\infty) \times S^1\) by \( X_{t, \varepsilon} \), the image of \((-\infty, -s_\varepsilon) \times S^1\) by \( X_{b, \varepsilon} \) and the image of \( B_{\rho_\varepsilon}(0) \) by \( X_{m, \varepsilon} \). The values of \( s_\varepsilon \) and \( \rho_\varepsilon \) have been chosen in such a way that the surface \( M^T_{k, \varepsilon} \) is contained in a neighbourhood of radius \( r_\varepsilon = \varepsilon/2 \) of \( \{0, 0\} \times \mathbb{R} \).

In this section, we will prove the existence of a family of minimal surfaces close to \( M^T_{k, \varepsilon} \). To aim we will use Proposition 8.1, and we will follow the work [6].

First, we modify the parametrization of the ends \( E_{t, \varepsilon}, E_{b, \varepsilon}, E_{m, \varepsilon} \) for appropriate values of \( s \) and \( x \), so that the images of \( r = r_\varepsilon \) by

\[
\theta \to (r \cos \theta, r \sin \theta, Z_b(\theta, r)), \quad \theta \to (r \cos \theta, r \sin \theta, Z_t(\theta, r))
\]
correspond, respectively, up to a vertical translation, to the horizontal curves at heights $\pm \varepsilon^2 \ln(2r_\varepsilon/\varepsilon^2)$.

The curve $\theta \to (r \cos \theta, r \sin \theta, Z_m(\theta, r))$, if $r = r_\varepsilon$, corresponds, up to a vertical translation, to a horizontal curve at height $\varepsilon^2 (r_\varepsilon/\varepsilon^2)^{-(k+1)}$.

The second step is the modification of the unit normal vector field on $M_{k,\varepsilon}$ into a transverse unit vector field $\tilde{n}_\varepsilon$ in such a way that it coincides with the normal vector field $n_\varepsilon$ on $M_{k,\varepsilon}$, is equal to $e_3$ on the graph over $B_{3r_\varepsilon} - Br_\varepsilon/2$ of the functions $U_t$ and $U_0$, and interpolates smoothly between the different definitions of $\tilde{n}_\varepsilon$ in different subsets of $M_{k,\varepsilon}$.

Finally we observe that close to $E_{t,\varepsilon}$, we can give the following estimate:

$$
|\varepsilon^4 \cosh^2 s \left( L_{M_{k,\varepsilon}} v - (\varepsilon^4 \cosh^2 s)^{-1} (\partial_{ss} v + \partial_{t0} v) \right) | \leq C |(\cosh^2 s)^{-1} v |.
$$

This follows easily from (53) together with the fact that $u_t$ decays at least like $(\cosh^2 s)^{-1}$ on $E_{t,\varepsilon}$. Similar considerations hold close to the bottom end $E_{0,\varepsilon}$. Near the middle planar end $E_{m,\varepsilon}$, we observe that the following estimate holds:

$$
|\varepsilon^4 |x|^{-4} \left( L_{M_{k,\varepsilon}} v - |x|^{4} \varepsilon^{-4} \Delta_0 v \right) | \leq C |x|^{2k+3} \nabla v |.
$$

This follows easily from (54) together with the fact that $u_m$ decays at least like $|x|^{k+1}$ on $E_{m,\varepsilon}$.

The graph of a function $u$, $\Sigma_u$, using the vector field $\tilde{n}_\varepsilon$, is a minimal surface (with respect to the metric $g_0$) if and only if $u$ is a solution of a second order nonlinear elliptic equation of the form

$$
H_\varepsilon(\Sigma_u) = L_{M_{k,\varepsilon}} u - \tilde{L}_\varepsilon u - Q_\varepsilon(\Sigma_u) = 0,
$$

where $L_{M_{k,\varepsilon}}$ is the Jacobi operator about $M_{k,\varepsilon}$, $Q_\varepsilon$ is a nonlinear second order differential operator and $\tilde{L}_\varepsilon$ is a linear operator which takes into account the change of the normal vector field (only for the top and bottom ends) $n_\varepsilon$ into $\tilde{n}_\varepsilon$ and of the change of the parametrization.

This operator is supported in a neighbourhood of $\{ \pm s_\varepsilon \} \times S^1$ and of $S^1 \times \{ \rho_\varepsilon \}$. It is possible to show that the coefficients of $\varepsilon^4 \tilde{L}_\varepsilon$ are uniformly bounded by a constant times $\varepsilon^4$. We start by noticing that the conformal factor $(\cosh^2 s)^{-1}$ contributes with a term equal to $\varepsilon^2$. Furthermore the fact that $\langle \tilde{n}_\varepsilon, n_\varepsilon \rangle = 1 + O_{C^2}(\varepsilon^2)$ in a neighbourhood of $\{ \pm s_\varepsilon \} \times S^1$ and the result of [15], appendix B, show that the change of vector field induces a linear operator whose coefficients are bounded by a constant times $\varepsilon^2$. The contribution of the change of parametrization can be estimated as follows.

Now, we consider three functions $\varphi_t, \varphi_b, \varphi_m \in C^{2,\alpha}(S^1)$ which are even, with respect to $\theta$, $\varphi_t$ is collinear to $\cos(j(k+1)\theta)$ ($k \geq 1$ fixed) with $j \geq 1$, $\varphi_b(\theta) = -\varphi_t(\theta - \frac{\pi}{k+1})$, while $\varphi_m$ is collinear to $\cos(l(k+1)\theta)$, with $l \geq 1$ and odd. Assume that they satisfy

$$
\|\varphi_t\|_{C^{2,\alpha}} + \|\varphi_b\|_{C^{2,\alpha}} + \|\varphi_m\|_{C^{2,\alpha}} \leq C \varepsilon^2.
$$

We set $\Phi := (\varphi_t, \varphi_b, \varphi_m)$ and we define $w_\Phi$ to be the function equal to

$$
(1) \quad \chi_+ H_{\varphi_t}(s_\varepsilon - s, \cdot) \quad \text{on the image of } X_{t,\varepsilon}, \text{where } \chi_+ \quad \text{is a cutoff function equal to } 0 \text{ for } s \leq s_0 + 1 \text{ and identically equal to } 1 \text{ for } s \in [s_0 + 2, s_\varepsilon];
$$
(2) \( \chi_+ H_{\rho_\epsilon}(s + s_\epsilon, \cdot) \) on the image of \( X_{\rho_\epsilon, \epsilon} \), where \( \chi_+ \) is a cutoff function equal to 0 for \( s \geq -s_0 - 1 \) and identically equal to 1 for \( s \in [-s_\epsilon, -s_0 - 2] \);

(3) \( \chi_m H_{\rho_\epsilon, \phi_\epsilon}(\cdot, \cdot) \) on the image of \( X_{\rho_\epsilon, \phi_\epsilon} \), where \( \chi_m \) is a cutoff function equal to 0 for \( \rho \geq \rho_0 \) and identically equal to 1 for \( \rho \in [\rho_\epsilon, \rho_0/2] \);

(4) zero on the remaining part of the surface \( M_{K, \epsilon}^T \).

The cutoff functions just introduced must have the same symmetry properties as the functions in \( C_{\delta}^{0, \alpha}(M_{K, \epsilon}) \). \( H \) and \( H \) are harmonic extension operators introduced respectively in Propositions 12.3 and 12.2.

We would like to prove that, under appropriate hypotheses, the graph \( \Sigma_u \) over \( M_{K, \epsilon}^T \) of the function \( u = w_\Phi + v \) is a minimal surface with respect to the metric \( g_{hyp} \). We want to point out that to construct the graph of the function \( u \), here we consider the normal vector field with respect to the Euclidean metric \( g_0 \). The equation to solve is:

\[
H_{hyp}(\Sigma_u) = 0.
\]

If we denote by \( N_u = (N_1(u), N_2(u), N_3(u)) \) the unit normal vector to \( \Sigma_u \), by equation (31) we can express \( H_{hyp}(\Sigma_u) \) in terms of the Euclidean mean curvature and write the equation to solve as

\[
H_e(\Sigma_u) = \mathcal{O}(x_1 N_1(u) + x_2 N_2(u)) + r^2 \mathcal{O}(\partial_{x_1} N_1(u) + \partial_{x_2} N_2(u)) = 0,
\]

where \( x_1, x_2 \) are the coordinates on \( \mathbb{B}^2 \) and \( r^2 = x_1^2 + x_2^2 \). To simplify the notation we set \( P(u) := \mathcal{O}(x_1 N_1(u) + x_2 N_2(u)) - r^2 \mathcal{O}(\partial_{x_1} N_1(u) + \partial_{x_2} N_2(u)) \). Taking into account that \( u = w_\Phi + v \), now the expression of the equation to solve is given by

\[
\mathcal{L}_{M_{K, \epsilon}^T}(w_\Phi + v) - \tilde{L}_\epsilon(w_\Phi + v) - Q_{\epsilon}(w_\Phi + v) - P(w_\Phi + v) = 0.
\]

The resolution of the previous equation is obtained by the fixed point problem:

\[
u = T(\Phi, v)
\]

with

\[
T(\Phi, v) = G_{\epsilon, \delta} \circ \mathcal{E}_\epsilon \left( \gamma \left( \tilde{L}_\epsilon(w_\Phi + v) + P(w_\Phi + v) - \mathcal{L}_{M_{K, \epsilon}^T} w_\Phi + Q_{\epsilon}(w_\Phi + v) \right) \right),
\]

where \( \delta \in (1, 2) \), the operator \( G_{\epsilon, \delta} \) is defined in Proposition 12.3 and \( \mathcal{E}_\epsilon \) is a linear extension operator such that

\[
\mathcal{E}_\epsilon : C_\epsilon^{0, \alpha}(M_{K, \epsilon}^T) \rightarrow C_\epsilon^{0, \alpha}(M_{K, \epsilon}),
\]

where \( C_\epsilon^{0, \alpha}(M_{K, \epsilon}^T) \) denotes the space of functions of \( C_\epsilon^{0, \alpha}(M_{K, \epsilon}) \) restricted to \( M_{K, \epsilon}^T \).

It is defined by \( \mathcal{E}_\epsilon v = v \) in \( M_{K, \epsilon}^T \), \( \mathcal{E}_\epsilon v = 0 \) in the image of \([s_\epsilon + 1, +\infty) \times S^1 \) by \( X_{t, \epsilon} \), in the image of \((-\infty, -s_\epsilon - 1) \) \times \( S^1 \) by \( X_{b, \epsilon} \) and in the image of \( B_{r, \epsilon} \) by \( X_{m, \epsilon} \). Finally \( \mathcal{E}_\epsilon v \) is an interpolation of these values in the remaining part of \( M_{K, \epsilon} \) such that

\[
(\mathcal{E}_\epsilon v) \circ X_{t, \epsilon}(s, \theta) = (1 + s_\epsilon - s)(v \circ X_{t, \epsilon}(s_\epsilon, \theta)), \quad \text{for } (s, \theta) \in [s_\epsilon, s_\epsilon + 1] \times S^1,
\]

\[
(\mathcal{E}_\epsilon v) \circ X_{b, \epsilon}(s, \theta) = (1 + s_\epsilon + s)(v \circ X_{b, \epsilon}(s_\epsilon, \theta)), \quad \text{for } (s, \theta) \in [-s_\epsilon - 1, -s_\epsilon] \times S^1,
\]

\[
(\mathcal{E}_\epsilon v) \circ X_{m, \epsilon}(\theta, \rho) = \left( \frac{2}{\rho_\epsilon} \rho - 1 \right) (v \circ X_{m, \epsilon}(\theta, \rho_\epsilon)) \quad \text{for } (\theta, \rho) \in S^1 \times [\rho_\epsilon/2, \rho_\epsilon].
\]
Remark 10.2. From the definition of $E_\varepsilon$, if $\text{supp} \ v \cap (B_{\rho_\varepsilon} - B_{\rho_\varepsilon/2}) \neq \emptyset$, then
\[
\|(E_\varepsilon v) \circ X_{m,\varepsilon}\|_{C^{0,\alpha}(B_{\rho_\varepsilon})} \leq c_\rho_\varepsilon^{-\alpha} \|v \circ X_{m,\varepsilon}\|_{C^{0,\alpha}(B_{\rho_\varepsilon} - B_{\rho_\varepsilon})}.
\]
This phenomenon of explosion of the norm does not occur near the catenoidal type ends:
\[
\|(E_\varepsilon v) \circ X_{t,\varepsilon}\|_{C^{0,\alpha}([-s_0, s_0] \times S^1)} \leq c \|v \circ X_{t,\varepsilon}\|_{C^{0,\alpha}([-s_0, s_0] \times S^1)}.
\]
A similar equation holds for the bottom end. In the following we will assume $\alpha > 0$ and close to zero.

The existence of a solution $v \in C^2(M_{k,\varepsilon}^T)$ for equation (54) is a consequence of the following result, which proves that $T(\Phi, \cdot)$ is a contraction mapping.

Lemma 10.3. Let $\delta \in (1, 2)$ and $\Phi = (\varphi_1, \varphi_2, \varphi_m) \in C^{2,\alpha}(S^1)^3$ satisfy (54) and enjoy the properties given above. There exist constants $c_\kappa > 0$ and $\varepsilon_0 > 0$, such that
\[
\|T(\Phi, 0)\|_{C^{2,\alpha}(M_{k,\varepsilon})} \leq c_\kappa \varepsilon^{5/2}
\]
and, for all $\varepsilon \in (0, \varepsilon_0)$, $\alpha \in (0, 1/2)$,
\[
\|T(\Phi, v_2) - T(\Phi, v_1)\|_{C^{2,\alpha}(M_{k,\varepsilon})} \leq \frac{1}{2} \|v_2 - v_1\|_{C^{2,\alpha}(M_{k,\varepsilon})},
\]
\[
\|T(\Phi_2, v) - T(\Phi_1, v)\|_{C^{2,\alpha}(M_{k,\varepsilon})} \leq c \varepsilon^{3/2} \|\Phi_2 - \Phi_1\|_{C^{2,\alpha}(S^1)},
\]
where $c$ is a positive constant, with
\[
\|\Phi_2 - \Phi_1\|_{C^{2,\alpha}(S^1)} = \|\varphi_2 - \varphi_1, 1\|_{C^{2,\alpha}(S^1)} + \|\varphi_{b,2} - \varphi_{b,1}\|_{C^{2,\alpha}(S^1)} + \|\varphi_{m,2} - \varphi_{m,1}\|_{C^{2,\alpha}(S^1)}
\]
for all $v, v_1, v_2 \in C^{2,\alpha}(M_{k,\varepsilon})$ and satisfying $\|v\|_{C^{2,\alpha}} \leq 2 c_\kappa \varepsilon^{5/2}$ and for all boundary data $\Phi_i = (\varphi_{i,j}, \varphi_{b,j}, \varphi_{m,j}) \in [C^{2,\alpha}(S^1)]^3$, $i = 1, 2$, enjoying the same properties as $\Phi$.

Proof. We recall that the Jacobi operator associated to $M_{k,\varepsilon}$, is asymptotic (up to a multiplication by $1/\varepsilon^4$) to the operator of the catenoid near the catenoidal ends, and it is asymptotic to the Laplacian near the planar ends. The function $w_\Phi$ is identically zero far from the ends where the explicit expression of $L_{M_{k,\varepsilon}}$ is not known: this is the reason for our particular choice in the definition of $w_\Phi$. Then from the definition of $w_\Phi$ and thanks to Proposition [53] we obtain the estimate
\[
\|E_\varepsilon (\gamma L_{M_{k,\varepsilon}} w_\Phi)\|_{C^{0,\alpha}_\varepsilon (M_{k,\varepsilon})}
\]
\[
= \left\| \left( \frac{\gamma L_{M_{k,\varepsilon}}}{\partial_s^2 + \partial^2_{\varepsilon}} \right) (w_\Phi \circ X_{t,\varepsilon}) \right\|_{C^{0,\alpha}([-s_0+1, s_0] \times S^1)}
\]
\[
+ \left\| \left( \frac{\gamma L_{M_{k,\varepsilon}}}{\partial_s^2 + \partial^2_{\varepsilon}} \right) (w_\Phi \circ X_{b,\varepsilon}) \right\|_{C^{0,\alpha}([-s_0-1, -s_0] \times S^1)}
\]
\[
+ \rho_\varepsilon^{-\alpha} \left\| \left( \frac{\gamma L_{M_{k,\varepsilon}}}{\Delta_0} \right) (w_\Phi \circ X_{m,\varepsilon}) \right\|_{C^{0,\alpha}(S^1 \times [\rho_{\varepsilon, \rho_0}])}
\]
\[
\leq c \|\cos^{-2} s (w_\Phi \circ X_{t,\varepsilon})\|_{C^{0,\alpha}([s_0+1, s_0] \times S^1)}
\]
\[
+ c \|\cos^{-2} s (w_\Phi \circ X_{b,\varepsilon})\|_{C^{0,\alpha}([-s_0-1, -s_0] \times S^1)}
\]
\[
+ c \varepsilon^{-\alpha} \|\rho^{2k-3} (w_\Phi \circ X_{m,\varepsilon})\|_{C^{0,\alpha}(S^1 \times [\rho_{\varepsilon, \rho_0}])}
\]
\[
\leq c_\kappa \varepsilon^{4} + c_\kappa \varepsilon^{5/2} \leq c_\kappa \varepsilon^{5/2}.
\]
To obtain this estimate we used the following:

\[
\sup_{[s_0,1,s_1] \times S^1} e^{-\delta s} \| s w_\Phi \circ X_{t,\varepsilon} / 2 \|_{C^{0,\alpha}([s_0,1] \times S^1)} \\
\leq c \sup_{[s_0,1,s_1] \times S^1} e^{-\delta s} e^{-2(s_1-s)} e^{-2s} \| \phi_t \|_{C^{2,\alpha}(S^1)} \leq c e^{-2s} \| \phi_t \|_{C^{2,\alpha}(S^1)} \leq c \varepsilon^4
\]

(a similar estimate holds for the bottom end) and

\[
\rho_{\varepsilon}^{-\alpha} \| 2^k + 3 \nabla (w_\Phi \circ X_{m,\varepsilon}) \|_{C^{0,\alpha}(S^1 \times [\rho_{\varepsilon}, \rho_0])} \leq c \varepsilon^{-\alpha} \rho_{\varepsilon} \| \phi_m \|_{C^{2,\alpha}(S^1)} \leq c \varepsilon^{5/2}
\]

together with the fact that \( s_\varepsilon = -\ln \varepsilon \) and \( \rho_{\varepsilon} = 2\varepsilon \), from which \( e^{-2s_{\varepsilon}} = \varepsilon^2 \) and \( \rho_{\varepsilon}^{-\alpha} = (2\varepsilon)^{-\alpha} \). Using the properties of \( \tilde{\gamma} \) (see (46)), we obtain

\[
\| \mathcal{E}_\varepsilon (\tilde{\gamma} L_\varepsilon \w_\Phi) \|_{C^{0,\alpha}(M_{\varepsilon},\varepsilon)} \leq c \varepsilon^2 \| w_\Phi \circ X_{t,\varepsilon} \|_{C^{0,\alpha}([s_0,1,s_1] \times S^1)} + \varepsilon^2 \| w_\Phi \circ X_{b,\varepsilon} \|_{C^{0,\alpha}([s_1,-s_0-1] \times S^1)} + \varepsilon^{2-\alpha} \| w_\Phi \circ X_{m,\varepsilon} \|_{C^{0,\alpha}(S^1 \times [\rho_{\varepsilon},\rho_0/2])} \leq c \varepsilon^{5/2}.
\]

The estimate of \( \| \mathcal{E}_\varepsilon (\gamma P(w_\Phi)) \|_{C^{0,\alpha}(M_{\varepsilon},\varepsilon)} \) is related to the estimate of the horizontal components and their derivatives of order one of the normal vector to the surface and to the definition of the function \( \gamma \) on \( M_{\varepsilon}^T \). It is convenient to recall that the operator \( \mathcal{E}_\varepsilon \) smoothly extends a function \( \gamma \in C^{0,\alpha}_0(M_{\varepsilon}^T) \) to a function in \( C^{0,\alpha}_0(M_{\varepsilon}^T) \), substantially leaving it unchanged on \( M_{\varepsilon}^T \), and setting it equal to zero on the remaining part of \( M_{\varepsilon}^T \). \( P \) keeps track of the difference of the mean curvature of \( \Sigma_u \) computed with respect to two different metrics. It is sufficient to estimate the norm of \( \gamma P(w_\Phi) \) only on \( M_{\varepsilon}^T \). The function \( \gamma \) equals \( \varepsilon^4 \cosh \varepsilon s \) at the catenoidal ends of \( M_{\varepsilon}^T \), equals \( \varepsilon^4 / |x|^4 \) at the middle end, and equals \( \varepsilon^4 \) far from the ends. We recall that \( |s| \in [s_0, s_1] \) and \( |x| = \rho \in [\rho_{\varepsilon}, \rho_0] \). Furthermore it is easy to prove that the horizontal components \( N_1, N_2 \) of the normal vector (with respect to the metric \( g_0 \)) to the graph of \( w_\Phi \) over the middle end of \( M_{\varepsilon}^T \) are, in absolute value, smaller than a constant times \( \varepsilon^2 \). Their derivatives \( \partial_{x_1} N_1, \partial_{x_2} N_2 \) are bounded by a constant times \( \varepsilon \). As for the values of the coordinates \( x_1 \) and \( x_2 \), we recall that we are working inside a cylindrical neighbourhood of radius \( r_{\varepsilon} = \varepsilon/2 \).

We get

\[
\| \mathcal{E}_\varepsilon (\gamma P(w_\Phi)) \|_{C^{0,\alpha}(M_{\varepsilon},\varepsilon)} \leq c \varepsilon^{5/2}.
\]

As for the last term, we recall that the expression of the operator \( Q_{\varepsilon} \) depends on the type of end we are considering (see equations (59) and (13)). It follows that

\[
\| \mathcal{E}_\varepsilon (\gamma Q_{\varepsilon}(w_\Phi)) \|_{C^{0,\alpha}(M_{\varepsilon},\varepsilon)} \leq c \varepsilon^{5/2}.
\]

In fact

\[
\| \mathcal{E}_\varepsilon (\gamma Q_{\varepsilon}(w_\Phi)) \|_{C^{0,\alpha}(M_{\varepsilon},\varepsilon)} \leq c \varepsilon^2 \| \frac{w_\Phi}{\varepsilon^2 \cosh s} \circ X_{t,\varepsilon} \|_{C^{1,\alpha}([s_0,1,s_1] \times S^1)} + c \varepsilon^2 \| \frac{w_\Phi}{\varepsilon^2 \cosh s} \circ X_{b,\varepsilon} \|_{C^{1,\alpha}([s_1,-s_0-1] \times S^1)} + c \varepsilon^{2(1-\alpha)} \| \frac{|x|^2}{\varepsilon^2} w_\Phi \circ X_{m,\varepsilon} \|_{C^{0,\alpha}(S^1 \times [\rho_{\varepsilon},\rho_0/2])} \leq c \varepsilon^{5/2}.
\]

As for the second estimate, we recall that

\[
T(\Phi, v) := G_{\varepsilon,\delta} \circ \mathcal{E}_\varepsilon \left( \gamma \left( P(w_\Phi + v) + L_\varepsilon(w_\Phi + v) - L_{M_{\varepsilon},\varepsilon} w_\Phi + Q_{\varepsilon}(w_\Phi + v) \right) \right).
\]
Then
\[
\|T(\Phi, v_2) - T(\Phi, v_1)\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})} \\
\leq \|E_\varepsilon (\gamma (P(w_\Phi + v_2) - P(w_\Phi + v_1)))\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})} \\
+ \|E_\varepsilon (\gamma \tilde{L}_\varepsilon(v_2 - v_1))\|_{c_\delta^{0,\alpha}(M_{k,\varepsilon})} \\
+ \|E_\varepsilon (\gamma (Q_\varepsilon (w_\Phi + v_1) - Q_\varepsilon (w_\Phi + v_2)))\|_{c_\delta^{0,\alpha}(M_{k,\varepsilon})}.
\]

We observe that from the considerations above it follows that
\[
\|E_\varepsilon (\gamma (P(w_\Phi + v_2) - P(w_\Phi + v_1)))\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})} \leq c\varepsilon^{3/2}\|v_2 - v_1\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})},
\]
\[
\|E_\varepsilon (\gamma \tilde{L}_\varepsilon(v_2 - v_1))\|_{c_\delta^{0,\alpha}(M_{k,\varepsilon})} \leq c\varepsilon^2\|v_2 - v_1\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})}
\]
and
\[
\|E_\varepsilon (\gamma (Q_\varepsilon (w_\Phi + v_1) - Q_\varepsilon (w_\Phi + v_2)))\|_{c_\delta^{0,\alpha}(M_{k,\varepsilon})} \\
\leq c_\kappa \varepsilon^2\|v_2 - v_1\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})}.
\]

Then
\[
\|T(\Phi, v_2) - T(\Phi, v_1)\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})} \leq c\varepsilon^{3/2}\|v_2 - v_1\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})}
\]

To show the last estimate it is sufficient to observe that
\[
\|T(\Phi_2, v) - T(\Phi_1, v)\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})} \leq \|E_\varepsilon (\gamma (P(w_{\Phi_2} + v) - P(w_{\Phi_1} + v)))\|_{c_\delta^{2,\alpha}(M_{k,\varepsilon})} \\
+ \|E_\varepsilon (\gamma \tilde{L}_\varepsilon(w_{\Phi_2} - w_{\Phi_1}))\|_{c_\delta^{0,\alpha}(M_{k,\varepsilon})} \\
+ \|E_\varepsilon (\gamma (Q_\varepsilon (w_{\Phi_2} + v) - Q_\varepsilon (w_{\Phi_1} + v)))\|_{c_\delta^{0,\alpha}(M_{k,\varepsilon})} \\
\leq c\varepsilon^{3/2}\|\Phi_2 - \Phi_1\|_{c_\delta^{2,\alpha}(S^1)} + c\|v\|_{c_\delta^{0,\alpha}(M_{k,\varepsilon})}\|\Phi_2 - \Phi_1\|_{c_\delta^{2,\alpha}(S^1)} \leq c\varepsilon^{3/2}\|\Phi_2 - \Phi_1\|_{c_\delta^{2,\alpha}(S^1)}.
\]

Theorem 10.4. Let \( B := \{ w \in C_\delta^{2,\alpha}(M_{k,\varepsilon}) | \| w \|_{c_\delta^{2,\alpha}} \leq 2c_\kappa \varepsilon^{5/2} \} \). Then the nonlinear mapping \( T(\Phi, \cdot) \) defined above has a unique fixed point \( v \) in \( B \).

Proof. The previous lemma shows that, if \( \varepsilon \) is chosen small enough, the nonlinear mapping \( T(\Phi, \cdot) \) is a contraction mapping from the ball \( B \) of radius \( 2c_\kappa \varepsilon^{5/2} \) in \( C_\delta^{2,\alpha}(M_{k,\varepsilon}) \) into itself. This value follows from the estimate of the norm of \( T(\Phi, 0) \). Consequently, thanks to the Schauder fixed point theorem, \( T(\Phi, \cdot) \) has a unique fixed point \( v \) in this ball.

This argument provides an embedded minimal surface with respect to the metric \( g_{hyp}, M_{k,\varepsilon}^T(\Phi) \), which is close to \( M_{k,\varepsilon}^T \) and has three boundaries. This surface close
to its upper and lower boundary is a vertical graph over the annulus $B_{r_{ε}} - B_{r_{ε}/2}$, with $r_{ε} = \varepsilon/2$, whose parametrization is, respectively, given by

$$U_{t}(θ, r) = \sigma_{t, ε} + \varepsilon^{2} \ln \left(\frac{2r}{ε^{2}}\right) + \mathcal{H}_{r_{ε}}(s_{ε} - \ln \frac{2r}{ε^{2}}, θ) + V_{t}(θ, r),$$

$$U_{b}(θ, r) = -U_{t} \left(θ - \frac{π}{k + 1}, r\right),$$

where $s_{ε} = -\ln ε$. Near the middle boundary, the surface is a vertical graph whose parametrization is

$$U_{m}(θ, r) = \tilde{H}_{r_{m}, ϕ_{m}} \left(θ, \frac{ε^{2}}{r}\right) + V_{m}(θ, r).$$

The boundaries of the surface correspond to $r = r_{ε}$. All the functions $V_{i}$, $i = t, m$, depend nonlinearly on $ε, ϕ$.

**Lemma 10.5.** The function $V_{i}(ε, ϕ_{i})$, for $i = t, b$, satisfies

$$||V_{i}(ε, ϕ_{i})(ε, r_{ε})||_{C^{2,α}(B_{1} - B_{1/2})} \leq cε^{2}$$

and

$$||V_{i}(ε, ϕ_{2}, s_{2}) - V_{i}(ε, ϕ_{1}, s_{1})||_{C^{2,α}(B_{1} - B_{1/2})} \leq cε^{3/2 - δ}||ϕ_{2, i} - ϕ_{1, i}||_{C^{2,α}(S^{1})}.$$  \hspace{1cm} (56)

The function $V_{m}(ε, ϕ)$ satisfies

$$||V_{m}(ε, ϕ)(ε, ρ_{ε})||_{C^{2,α}(B_{1} - B_{1/2})} \leq cε^{2}$$

and

$$||V_{m}(ε, ϕ, m_{2})(ε, ρ_{ε}) - V_{m}(ε, ϕ, m_{1})(ε, ρ_{ε})||_{C^{2,α}(B_{1} - B_{1/2})} \leq cε^{3/2}||ϕ_{m, 2} - ϕ_{m, 1}||_{C^{2,α}(S^{1})}.$$  \hspace{1cm} (57)

**Proof.** We start by observing that the functions $V_{t}, V_{b}, V_{m}$ are the restrictions to $E_{t, ε}, E_{b, ε}, E_{m, ε}$ of a fixed point for the operator $T(Φ, ·)$. Then the second estimate follows from

$$||V_{i}(ε, ϕ_{2}, s_{2})(ε, ·) - V_{i}(ε, ϕ_{1}, s_{1})(ε, ·)||_{C^{2,α}(B_{1} - B_{1/2})} \leq cε^{3/2}||T(Φ_{1}, V_{i}) - T(Φ_{2}, V_{i})||_{C^{2,α}(B_{1} - B_{1/2})} \leq X_{i, ε}||C^{2,α}(Ω, S^{1})||,$$

for $i = t, b$, with $Ω_{t} = [s_{0}, s_{ε}]$ and $Ω_{b} = [-s_{ε}, -s_{0}]$. The third estimate comes from

$$||V_{m}(ε, ϕ_{m, 2})(ε, ·) - V_{m}(ε, ϕ_{m, 1})(ε, ·)||_{C^{2,α}(B_{1} - B_{1/2})} \leq c||T(Φ_{2}, V_{m}) - T(Φ_{1}, V_{m})||_{C^{2,α}(S^{1} \times [ρ_{ε}, ρ_{0}])}. \hspace{1cm} \square$$

11. The matching of Cauchy data

In this section we will complete the proof of Theorem [11]

Using the result of section 7, we obtain two minimal surfaces that are perturbations of two parts of the catenoid defined in $M^{2} \times R$. The first surface, which we denote by $S_{t, d_{t}}(ϕ_{t})$, after a translation by $d_{t}$ along the $x_{3}$-axis, can be parameterized in $B_{2r_{ε}} - B_{r_{ε}}$ as the vertical graph of

$$\bar{U}_{t}(θ, r) = ε^{2} ln \left(\frac{2r}{ε^{2}}\right) + d_{t} + \mathcal{H}_{r_{ε}, ϕ_{t}}(θ, r) + O_{C^{2,α}}(ε^{2}).$$

The second surface, which we denote by $S_{b, d_{b}}(ϕ_{b})$, where $ϕ_{b}(θ) = ϕ_{t}(θ - \frac{π}{k + 1})$ and $d_{b} = -d_{t}$, can be parameterized in $B_{2r_{ε}} - B_{r_{ε}}$ as the vertical graph of

$$\bar{U}_{b}(θ, r) = -\bar{U}_{t} \left(θ - \frac{π}{k + 1}, r\right).$$

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Using the result of section \[5\] we can construct the minimal graph \(S_m(\varphi_m)\). It can be parameterized in \(B_{2r_e} - B_{r_e}\) as the vertical graph of

\[
U_m(\theta, r) = H_{r_e, \varphi_m}(\theta, r) + \mathcal{O}_{C^{2,\alpha}_b}(\varepsilon^2).
\]

By the result of section \[10\] we can obtain a minimal surface \(M^T_{k,\varepsilon}(\Psi)\), with \(\Psi = (\psi_t, \psi_b, \psi_m)\), where \(\psi_b(\theta) = \psi_b(\theta - \frac{\pi}{k+1})\), which is close to a truncated and scaled genus \(k\) Costa-Hoffman-Meeks surface and has three boundaries. This surface is close to its upper and lower boundary, and is a vertical graph over the annulus \(B_{r_e} - B_{r_e/2}\), whose parametrization is, respectively, given by

\[
U_\ell(\theta, r) = \sigma_{\ell, \varepsilon} + \varepsilon^2 \ln \left(\frac{2r}{\varepsilon^2}\right) + H(\psi_\ell) \left( s_\varepsilon - \ln \left(\frac{2r}{\varepsilon^2}\right) \theta \right) + \mathcal{O}_{C^{2,\alpha}_b}(\varepsilon^2),
\]

\[
U_b(\theta, r) = -U_t \left( \theta - \frac{\pi}{k+1}, r \right),
\]

where \(s_\varepsilon = -\ln \varepsilon\). Near the middle boundary, the surface is a vertical graph whose parametrization is

\[
U_m(\theta, r) = \bar{H}_{\rho_a, \psi_m} \left( \theta, \frac{\varepsilon^2}{r} \right) + \mathcal{O}_{C^{2,\alpha}_b}(\varepsilon^2).
\]

We assume that the parameters and the boundary functions are chosen so that

\[
|\eta_t| + |\eta_b| + \|\varphi_t\|_{C^{2,\alpha}(S^1)} + \|\varphi_m\|_{C^{2,\alpha}(S^1)} + \|\psi_\ell\|_{C^{2,\alpha}(S^1)} + \|\psi_m\|_{C^{2,\alpha}(S^1)} \leq \kappa \varepsilon^2,
\]

where \(\eta_t = d_\ell - \sigma_{\ell, \varepsilon}\), and the constant \(\kappa > 0\) is fixed large enough. The functions \(\mathcal{O}_{C^{2,\alpha}_b}(\varepsilon^2)\) replace the functions \(V_t, V_m, \bar{V}_t, \bar{V}_m\) that appear at the end of sections \[5\], \[7\] and \[10\]. They depend nonlinearly on the different parameters and boundary data functions but they are bounded by a constant (independent of \(\kappa\) and \(\varepsilon\)) times \(\varepsilon^2\) in the \(C^{2,\alpha}_b\) topology, where partial derivatives are taken with respect to the vector fields \(r \partial_\ell\) and \(\partial_b\). It remains to show that, for all \(\varepsilon\) small enough, it is possible to choose the parameters and boundary functions in such a way that the surface

\[
S_{t, d_\ell}(\varphi_t) \cup S_{b, d_b}(\varphi_b) \cup S_m(\varphi_m) \cup M^T_{k,\varepsilon}(\Psi)
\]

is a \(C^1\) surface across the boundaries of the different summands. Regularity theory will then ensure that this surface is in fact smooth and by construction it has the desired properties. We point out that, in this way, we will have constructed a one-parameter family of minimal surfaces: each one of them is determined by a different value of the parameter \(\varepsilon\). Therefore this will complete the proof of the main theorem.

It is necessary to fulfill the following system of equations:

\[
\begin{cases}
U_t(\cdot, r_e) = \bar{U}_t(\cdot, r_e) \\
U_b(\cdot, r_e) = \bar{U}_b(\cdot, r_e) \\
U_m(\cdot, r_e) = \bar{U}_m(\cdot, r_e) \\
\partial_\ell U_b(\cdot, r_e) = \partial_\ell \bar{U}_b(\cdot, r_e) \\
\partial_\ell U_t(\cdot, r_e) = \partial_\ell \bar{U}_t(\cdot, r_e) \\
\partial_\ell U_m(\cdot, r_e) = \partial_\ell \bar{U}_m(\cdot, r_e)
\end{cases}
\]

\[\text{(60)}\]
on $S^1$. The first three equations together with the following identities,
\[ H_{\psi_t}(s_\theta - \ln(2r)/\varepsilon^2, \theta) \big|_{r=r_x} = \psi_t(\theta), \quad H_{\psi_b}(s_\theta, \varepsilon^2/r) \big|_{r=r_x} = \psi_m(\theta), \]
\[ \mathcal{H}_{r \cdot \psi_t}(\theta, r) \big|_{r=r_x} = \varphi_1(\theta), \quad \mathcal{H}_{r \cdot \psi_m}(\theta, r) \big|_{r=r_x} = \varphi_m(\theta), \]
lead to the system
\[
\begin{aligned}
\eta_t + \varphi_t - \psi_t &= O_{C^{1,\alpha}_b}(\varepsilon^2) \\
\varphi_m - \psi_m &= O_{C^{1,\alpha}_b}(\varepsilon^2),
\end{aligned}
\]
where $\eta_t = d_t - \sigma_{t,\varepsilon}$. The relations (58) and (59) allowed us to omit one equation. The last three equations give the system (we applied Lemmas 11.1 and 11.1.1)
\[
\begin{aligned}
\partial_\theta^2(\varphi_t + \psi_t) &= O_{C^{1,\alpha}_b}(\varepsilon^2) \\
\partial_\theta^2(\varphi_m + \psi_m) &= O_{C^{1,\alpha}_b}(\varepsilon^2).
\end{aligned}
\]
Here $\partial_\theta^2$ denotes the operator which associates to $\phi = \sum_{i \geq 1} \phi_i \cos(i\theta)$ the function $\partial_\theta^2 \phi = \sum_{i \geq 1} i \phi_i \cos(i\theta)$. The functions $O_{C^{1,\alpha}_b}(\varepsilon^2)$ in the above expansions depend nonlinearly on the different parameters and boundary data functions, but they are bounded by a constant (independent of $\kappa$ and $\varepsilon$) times $\varepsilon^2$ in the $C^{1,\alpha}_b$ topology. Projecting every equation of this system over the $L^2$-orthogonal complement of $\text{Span}\{1\}$, we obtain the system
\[
\begin{aligned}
\varphi_t - \psi_t &= O_{C^{1,\alpha}_b}(\varepsilon^2) \\
\varphi_m - \psi_m &= O_{C^{1,\alpha}_b}(\varepsilon^2) \\
\partial_\theta^2 \varphi_t + \partial_\theta^2 \psi_t &= O_{C^{1,\alpha}_b}(\varepsilon^2) \\
\partial_\theta^2 \varphi_m + \partial_\theta^2 \psi_m &= O_{C^{1,\alpha}_b}(\varepsilon^2).
\end{aligned}
\]

**Lemma 11.1.** The operator $h$, defined by
\[ C^{2,\alpha}(S^1) \to C^{1,\alpha}(S^1) \]
\[ \varphi \to \partial_\theta^2 \varphi, \]
acting on functions that are orthogonal to the constant function in the $L^2$-sense and are even, is invertible.

**Proof.** We observe that if we decompose $\varphi = \sum_{j \geq 1} \varphi_j \cos(j\theta)$, then
\[ h(\varphi) = \sum_{j \geq 1} \varphi_j \cos(j\theta), \]
which is clearly invertible from $H^1(S^1)$ into $L^2(S^1)$. Now elliptic regularity theory implies that this is also the case when this operator is defined between Hölder spaces.

Using this result, the system (53) can be rewritten as
\[ (\varphi_t, \varphi_m, \psi_t, \psi_m) = O_{C^{2,\alpha}_b}(\varepsilon^2). \]
Recall that the right hand side depends nonlinearly on $\varphi_t, \varphi_m, \psi_t, \psi_m$ and also on the parameter $\eta$. We look at this equation as a fixed point problem and fix $\kappa$ large enough. Thanks to the estimates (12), (29), (54) with $\delta \in (1, 3/2)$, and (57), we can use a fixed point theorem for contraction mappings in the ball of radius $\kappa \varepsilon^2$ in $(C^{2,\alpha}(S^1))^4$ to obtain, for all $\varepsilon$ small enough, a solution $(\varphi_t, \varphi_m, \psi_t, \psi_m)$ of (64). Since the right hand side of (63) is continuous with respect to all data, we see that the fixed point $(\varphi_t, \varphi_m, \psi_t, \psi_m)$ depends continuously (and in fact smoothly) on
the parameter \( \eta_t \). Inserting the found solution into (61) and (62), we see that it remains to solve an equation that can be rewritten as
\[
(65) \quad \eta_t = O(\varepsilon^2),
\]
where this time, the right hand side depends nonlinearly on \( \eta_t \). Now, provided \( \kappa \) has been fixed large enough, we can use the Schauder fixed point theorem in the ball of radius \( \kappa \varepsilon^2 \) in \( \mathbb{R} \) to solve (65), for all \( \varepsilon \) small enough. This provides a set of parameters and boundary data such that (61) and (62) hold. Equivalently we have proved the existence of a solution of system (60). So the proof of Theorem 1.1 is complete.

12. Appendix

12.1. Harmonic extension operators. The results contained in this section are about the existence of some harmonic extension operators. The first one gives the harmonic extension of a function defined on \( \partial B_{r_0} \) to \( D_2 \setminus B_{r_0} \).

Proposition 12.1. There exists an operator
\[
H_{r_0} : C^{2,\alpha}(S^1) \to C^{2,\alpha}(S^1 \times [r_0, 1]),
\]
such that for every even function \( \varphi(\theta) \in C^{2,\alpha}(S^1) \), the function \( w_\varphi = H_{r_0, \varphi} \) solves
\[
\begin{align*}
\Delta_0 w_\varphi &= 0 & \text{on } S^1 \times [r_0, 1] \\
w_\varphi &= \varphi & \text{on } S^1 \times \{r_0\} \\
w_\varphi &= 0 & \text{on } S^1 \times \{1\}.
\end{align*}
\]
Moreover,
\[
\|H_{r_0, \varphi}\|_{C^{2,\alpha}(S^1 \times [r_0, 1])} \leq c \|
\varphi\|_{C^{2,\alpha}(S^1)},
\]
for some constant \( c > 0 \).

\( S^1 \times [r_0, 1] \) being a compact domain, the existence of the solution of the Dirichlet problem above is a classical result; for example, see Theorem 2.14 of [4].

The uniqueness of the solution follows from the maximum principle. To get the wanted estimate of the norm of the solution, we observe that the maximum principle also implies that \( \sup |w_\varphi| \leq c \sup |\varphi| \) and that we can obtain similar estimates (involving the derivatives of \( \varphi \)) for the norm of the derivatives of \( w_\varphi \) from their harmonicity.

Now we give the statement of a result whose proof is contained in [3].

Proposition 12.2. There exists an operator
\[
H : C^{2,\alpha}(S^1) \to C^{2,\alpha}_{[-2]}([0, +\infty) \times S^1),
\]
such that for all \( \varphi \in C^{2,\alpha}(S^1) \), even functions and orthogonal to \( e_i, i = 0, 1 \), in the \( L^2 \)-sense, the function \( w = H_\varphi \) solves
\[
\begin{align*}
(\partial^2_\theta + \partial^2_\varphi) w &= 0 & \text{in } S^1 \times [0, +\infty) \\
w &= \varphi & \text{on } S^1 \times \{0\}.
\end{align*}
\]
Moreover
\[
\|H_\varphi\|_{C^{2,\alpha}_{[-2]}(S^1 \times [0, +\infty))} \leq c \|
\varphi\|_{C^{2,\alpha}(S^1)},
\]
for some constant \( c > 0 \).

The following result gives a harmonic extension of a function on \( \mathbb{R}^2 \setminus D_\rho \).
Proposition 12.3. There exists an operator
\[ \tilde{H}_\rho : C^{2,\alpha}(S^1) \rightarrow C^{2,\alpha}(S^1 \times [\bar{\rho}, +\infty]), \]
such that for each even function \( \varphi(\theta) \in C^{2,\alpha}(S^1) \), which is \( L^2 \)-orthogonal to the constant function, then \( w_\varphi = \tilde{H}_{\rho,\varphi} \) solves
\[
\begin{cases}
\Delta w_\varphi = 0 & \text{on } S^1 \times [\bar{\rho}, +\infty) \\
w_\varphi = \varphi & \text{on } S^1 \times \{\bar{\rho}\}.
\end{cases}
\]
Moreover,
\[
||\tilde{H}_{\rho,\varphi}||_{C^{2,\alpha}(S^1 \times [\bar{\rho}, +\infty])} \leq c||\varphi||_{C^{2,\alpha}(S^1)},
\]
for some constant \( c > 0 \).

Proof. We consider the decomposition of the function \( \varphi \) with respect to the basis \( \{\cos(i\theta)\} \), that is,
\[
\varphi = \sum_{i=1}^{\infty} \varphi_i \cos(i\theta).
\]
Then the solution \( w_\varphi \) is given by
\[
w_\varphi(\theta, \rho) = \sum_{i=1}^{\infty} \left( \frac{\rho}{\bar{\rho}} \right)^i \varphi_i \cos(i\theta).
\]
Since \( \frac{\rho}{\bar{\rho}} \leq 1 \), then \( \left( \frac{\rho}{\bar{\rho}} \right)^i \leq \left( \frac{\rho}{\bar{\rho}} \right) \), we can conclude that \( |w(\theta, \rho)| \leq c|\varphi(\theta)| \) and then \( ||w_\varphi||_{C^{2,\alpha}} \leq c||\varphi||_{C^{2,\alpha}}. \)

Lemma 12.4. Let \( u(\theta, r) \) be the harmonic extension defined on \( S^1 \times [r_0, +\infty) \) of the even function \( \varphi = \sum_{i \geq 0} \varphi_i \cos(i\theta) \in C^{2,\alpha}(S^1) \) and such that \( u(\theta, r_0) = \varphi(\theta) \). Then
\[
\partial^*_\rho \varphi(\theta) = r_0 \partial_r u(\theta, r)|_{r=r_0}.
\]

Proof. If \( \varphi(\theta) = \sum_{i \geq 0} \varphi_i \cos(i\theta) \), then the function \( u \) is given by
\[
u(\theta, r) = \sum_{i \geq 0} \varphi_i \left( \frac{r}{r_0} \right)^i \cos(i\theta).
\]
Then
\[
\partial_r u(\theta, r) = \sum_{i \geq 1} \varphi_i \left( \frac{r}{r_0} \right)^i \frac{i \cos(i\theta)}{r}.
\]
Consequently
\[
\partial^*_\rho \varphi(\theta) = r_0 \partial_r u(\theta, r)|_{r=r_0}.
\]

Lemma 12.5. Let \( u(\theta, r) \) be the harmonic extension defined on \( S^1 \times [0, r_0] \) of the even function \( \varphi \in C^{2,\alpha}(S^1) \) and such that \( u(\theta, r_0) = \varphi(\theta) \). Then
\[
\partial^*_\rho \varphi(\theta) = -r_0 \partial_r u(\theta, r)|_{r=r_0}.
\]

Proof. If \( \varphi(\theta) = \sum_{i \geq 0} \varphi_i \cos(i\theta) \), then the function \( u \) is given by
\[
u(\theta, r) = \sum_{i \geq 0} \varphi_i \left( \frac{r_0}{r} \right)^i \cos(i\theta).
\]
Then
\[ \partial_r u(\theta, r) = -\sum_{i \neq 1} \varphi_i \left( \frac{r_0}{r} \right)^i i \cos(i\theta). \]
Consequently
\[ \partial_\theta \varphi^*(\theta) = -r_0 \partial_r u(\theta, r)|_{r=r_0}. \]

12.2. The proof of Proposition 12.2. We start by giving the statement of a classical result about the injectivity of \( \Delta_0 \).

**Lemma 12.6.** Given \( 0 < r_0 < r_1 \leq 1 \), let \( w \) be a solution of \( \Delta_0 w = 0 \) on \( S^1 \times [r_0, r_1] \) such that \( w(\cdot, r_0) = w(\cdot, r_1) = 0 \). Then \( w = 0 \).

As a consequence of Lemma 12.6 the operator \( \Delta_0 \) is injective. Hence, the Fredholm alternative assures that there exists a unique \( w \in C^{2,\alpha}(S^1 \times [r_0, 1]) \), with \( w(\theta, r) \) satisfying:

\[
\begin{align*}
\Delta_0 w &= f \quad \text{on } S^1 \times [r_0, 1] \\
w(\cdot, r_0) &= w(\cdot, 1) = 0.
\end{align*}
\]

(68)

We want to prove the following assertion.

**Assertion 12.7.** For every \( 0 < r_0 < 1 \), \( f \in C^{0,\alpha}(S^1 \times [r_0, 1]) \) and \( w \in C^{2,\alpha}(S^1 \times [r_0, 1]) \), there exists a constant \( c \) such that

\[ \|w\|_{C^{0,\alpha}(S^1 \times [r_0, 1])} \leq c \|f\|_{C^{0,\alpha}(S^1 \times [r_0, 1])}. \]

We suppose by contradiction that the assertion (12.7) is false; that is, there does not exist a universal constant for which the previous estimate holds. Then, for each \( n \in \mathbb{N} \), there exist \( r_{0,n} \) and \( f_n, w_n \) satisfying (68) (with \( r_{0,n}, f_n, w_n \) instead of \( r_0, f, w \)) such that

\[ \sup_{S^1 \times [r_{0,n}, 1]} |f_n| = 1 \quad \text{and} \quad A_n := \sup_{S^1 \times [r_{0,n}, 1]} |w_n| \to +\infty \quad \text{as} \quad n \to \infty. \]

Since \( S^1 \times [r_{0,n}, 1] \) is a compact set, \( A_n \) is achieved at a point \( (\theta_n, r_n) \in S^1 \times [r_{0,n}, 1] \).

The sequence of sets \( I_n = [\frac{r_{0,n}}{r_n}, \frac{1}{r_n}] \) converges (up to some subsequence) to a set that we denote by \( I_\infty \). We will show that it is nonempty and contains 1. If \( r_{0,n} < r' < r'' < 1 \), elliptic estimates allow us to conclude that

\[ \sup_{S^1 \times [r_{0,n}, r'']} |\nabla w_n| \leq c \left( \sup_{S^1 \times [r_{0,n}, r'']} |f_n| + \sup_{S^1 \times [r_{0,n}, r'']} |w_n| \right) \leq c(1 + A_n), \]

where \( c \) is a constant independent of \( n \).

Then, if \( n \to +\infty \), \( \frac{r_{0,n}}{r_n} \to R_1 < 1 \) and \( \frac{1}{r_n} \to R_2 > 1 \). The fact that \( R_1 < 1 \) follows from the above estimate for the gradient of \( w_n \) near \( r = r_{0,n} \). That implies that the supremum \( A_n \) cannot be achieved at a point which is too close to \( r_{0,n} \), that is, the point where \( w_n \) vanishes. In other terms, the quotient \( \frac{r_{0,n}}{r_n} \) remains bounded away from 1. Using similar arguments it is possible to show that \( \nabla w_n \) is bounded near 1 and consequently \( \frac{1}{r_n} \) also remains bounded away from 1. Then we can conclude that \( I_\infty \) is not empty. We set \( I_\infty = [R_1, R_2] \), where \( 0 \leq R_1 < 1 < R_2 < +\infty \in \mathbb{R} \).

We define
\[ \tilde{w}_n(\theta, r) := \frac{1}{A_n} w_n(\theta, rr_n) \quad \text{and} \quad \tilde{f}_n(\theta, r) := \frac{1}{A_n} f_n(\theta, rr_n), \]

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
for all \((\theta, r) \in S^1 \times I_n\), with \(I_n = [r_{0,n}/r_n, 1/r_n]\). These functions satisfy \(r_n^2 \Delta \tilde{w}_n = \tilde{f}_n\).

From the definition of \(\tilde{w}_n\), we obtain that
\[
\nabla \tilde{w}_n = \frac{1}{A_n} \nabla w_n(\theta, rr_n).
\]
Then
\[
|\nabla \tilde{w}_n| \leq c \frac{1 + A_n}{A_n} < 2c.
\]
Since the sequences \((\tilde{w}_n)_n\) and \((\nabla \tilde{w}_n)_n\) are uniformly bounded, the Ascoli-Arzelà theorem assures that a subsequence of \((\tilde{w}_n)_n\) converges on compact sets of \(S^1 \times I_\infty\) to a nonzero function \(w_\infty\) that vanishes on \(S^1 \times \partial I_\infty\). The function \(w_\infty\) inherits the properties of \(\tilde{w}_n\). In particular,
\[
(69) \quad \sup_{S^1 \times I_\infty} |w_\infty| = 1.
\]

In the same way it’s possible to prove that a subsequence of \((\tilde{f}_n)_n\) converges on compact sets of \(S^1 \times I_\infty\) to the function \(f_\infty \equiv 0\) since, if \(n \to \infty\),
\[
\sup_{S^1 \times I_n} |\tilde{f}_n| \to 0.
\]

Then the limit function \(w_\infty\) must satisfy the differential equation
\[
\Delta_0 w_\infty = 0
\]
on \(S^1 \times I_\infty\) with null boundary conditions on \(\partial I_\infty\). So we can conclude that \(\forall r \in I_\infty\), \(w_\infty(\theta, r) = 0\). This function does not satisfy \((69)\), a contradiction. This proves the assertion \(12.7\).

The elliptic estimate,
\[
|\nabla w| \leq c \left( \sup_{S^1 \times [r_0, 1]} |f| + \sup_{S^1 \times [r_0, 1]} |w| \right),
\]
allows us to get a uniform estimate of \(\nabla w\). This proves the existence of a solution of \(\Delta_0 w = f\) defined on \(S^1 \times [r_0, 1]\) for which
\[
\|w\|_{C^{0,\alpha}(S^1 \times [r_0, 1])} \leq c \|f\|_{C^{0,\alpha}(S^1 \times [r_0, 1])}.
\]
Now it is sufficient again to use elliptic estimates to obtain the estimates for the derivatives.

12.3. Minimal graphs in \((D^2 \times \mathbb{R}, g_{hyp})\). In this section, following [17], we will find the condition to be satisfied such that the graph \(\Sigma\) of a function defined on \(D^2\) is minimal with respect to the metric \(g_{hyp} = \frac{dx_1^2 + dx_2^2}{F} + dx_3^2\), where \(F = (1 - x_1^2 - x_2^2)^2\). We assume that the immersion of \(\Sigma\) in \(D^2 \times \mathbb{R}\) is given by
\[
(x_1, x_2) \to (x_1, x_2, u(x_1, x_2)).
\]

The Christoffel symbols, \(\Gamma^k_{ij}\), associated to \(g_{hyp}\) all vanish except
\[
\Gamma^1_{11} = \Gamma^2_{21} = \Gamma^2_{12} = -\Gamma^1_{22} = \frac{2x_1}{\sqrt{F}},
\]
\[
\Gamma^1_{12} = \Gamma^2_{22} = \Gamma^1_{21} = -\Gamma^2_{11} = \frac{2x_2}{\sqrt{F}}.
\]
Let $e_1, e_2, e_3$ be the canonical basis of $\mathbb{R}^3$. Then $e_1 = \sqrt{F}e_1, e_2 = \sqrt{F}e_2, e_3 = e_3$ is an orthonormal basis for $\mathbb{M}^2 \times \mathbb{R}$. The coordinate vector fields on $\Sigma$ are
\[ X_1 = \frac{e_1}{\sqrt{F}} + u'_x e_3, \quad X_2 = \frac{e_2}{\sqrt{F}} + u'_x e_3, \quad N = \frac{1}{W} \left( -u''_x \sqrt{F} e_1 + u'_x \sqrt{F} e_2 + e_3 \right), \]
with $W = \sqrt{1 + F |u'|^2}$. The induced metric on $\Sigma$ is defined by
\[ g_{11} = \frac{1}{F} + (u'_x)^2, \quad g_{22} = \frac{1}{F} + (u''_x)^2, \quad g_{12} = u''_{x_1 x_2}. \]
If $\nabla$ denotes the Riemannian connection of the metric $g_{hyp}$, then the coefficients of the second fundamental form are
\[ b_{11} = \langle \nabla X_1, X_1, N \rangle = \frac{1}{W} \left( -\frac{2x_1}{\sqrt{F}} u'_x + \frac{2x_2}{\sqrt{F}} u''_x + u''_{x_1 x_1} \right), \]
\[ b_{22} = \langle \nabla X_2, X_2, N \rangle = \frac{1}{W} \left( \frac{2x_1}{\sqrt{F}} u'_x - \frac{2x_2}{\sqrt{F}} u''_x + u''_{x_2 x_2} \right), \]
\[ b_{12} = \langle \nabla X_1, X_2, N \rangle = \frac{1}{W} \left( -\frac{2x_2}{\sqrt{F}} u'_x - \frac{2x_1}{\sqrt{F}} u''_x + u''_{x_1 x_2} \right), \]
where we used the following identities:
\[ \nabla X_1, X_1 = 2x_1 e_1 - 2x_2 e_2 + u''_{x_1 x_1} e_3, \quad \nabla X_2, X_2 = -2x_1 e_1 + 2x_2 e_2 + u''_{x_2 x_2} e_3, \]
\[ \nabla X_1, X_2 = 2x_2 e_1 + 2x_1 e_2 + u''_{x_1 x_2} e_3. \]
The mean curvature of $\Sigma$ with respect to $g_{hyp}$ is given by
\[ H(\Sigma) = \frac{1}{2} \frac{b_{11} g_{22} + b_{22} g_{11} - 2 b_{12} g_{12}}{g_{11} g_{22} - g_{12}^2}. \]
Using the expressions of the coefficients of the first and second fundamental form, we find that
\[ H(\Sigma) = \frac{F}{2} \text{div} \left( \frac{\nabla u}{\sqrt{1 + F |u|^2}} \right). \]

12.4. Minimal surfaces of rotation in $(\mathbb{D}^2 \times \mathbb{R}, g_{hyp})$. In this section, following [7], we will find the condition to be satisfied such that a surface of revolution $\Sigma$ in $\mathbb{D}^2 \times \mathbb{R}$ is minimal with respect to the metric $g_{hyp} = \frac{4x^2 + d\theta^2}{F} + dz^2$, where $F = (1 - x^2 - x^2)^2$. We will assume that the immersion of $\Sigma$ in $\mathbb{D}^2 \times \mathbb{R}$ is given, in terms of the cylindrical coordinates $(r, \theta, z)$, by:
\[ (\theta, z) \rightarrow (r(z), \theta, z), \]
where $r(z)$ is a function of $z$.

It is convenient to express the metric $g_{hyp}$ in terms of the new coordinates. We find
\[ g_{hyp} = \frac{dr^2 + r^2 d\theta^2}{F} + dz^2, \]
with $F = (1 - r^2)^2$. The Christoffel symbols, $\Gamma^k_{ij}$, associated to $g_{hyp}$ all vanish except
\[ \Gamma^1_{11} = \frac{2r}{1-r^2}, \quad \Gamma^1_{22} = -\frac{r(1+r^2)}{1-r^2}, \quad \Gamma^2_{21} = \frac{1+r^2}{r(1-r^2)}. \]
Let $e_1, e_2, e_3$ be the canonical basis of $\mathbb{R}^3$. Then the coordinate vector fields on $\Sigma$ are
\[ X_1 = r'(z)e_1 + e_3, \quad X_2 = e_2, \quad N = \frac{-e_1 + r'(z)e_3}{R}, \]
with $R = \sqrt{1 + (r'(z))^2}$. The induced metric on $\Sigma$ is defined by
\[ g_{11} = \frac{(r'(z))^2}{R} + 1, \quad g_{22} = \frac{r^2(z)}{R}, \quad g_{12} = 0. \]
If $\nabla$ denotes the Riemannian connection of the metric $g_{hyp}$, then the coefficients of the second fundamental form are
\begin{align*}
    b_{11} &= \langle \nabla_{X_1}X_1, N \rangle = -\frac{1}{RF} \left(\frac{2r(r')^2}{1 - r^2} + r''\right), \\
    b_{22} &= \langle \nabla_{X_2}X_2, N \rangle = \frac{1}{RF} \left(\frac{r(1 + r^2)}{1 - r^2}\right), \\
    b_{12} &= \langle \nabla_{X_1}X_2, N \rangle = 0,
\end{align*}
where we used the following identities:
\begin{align*}
    \nabla_{X_1}X_1 &= \frac{2r(r')^2}{1 - r^2} + r'' e_1, \\
    \nabla_{X_2}X_2 &= \frac{r(1 + r^2)}{1 - r^2} e_1, \\
    \nabla_{X_1}X_2 &= \frac{r'(1 + r^2)}{r(1 - r^2)} e_2.
\end{align*}
The mean curvature of $\Sigma$ with respect to $g_{hyp}$ is given by
\[ H(\Sigma) = \frac{1}{2} \frac{b_{11}g_{22} + b_{22}g_{11} - 2b_{12}g_{12}}{g_{11}g_{22} - g_{12}^2}. \]
Using the expressions of the coefficients of the first and second fundamental form, we find that $H(\Sigma) = 0$ if the function $r(z)$ satisfies the following differential equation:
\[ r(z)r''(z) - (r'(z))^2 - (1 - r(z))^4 = 0. \]
