FORCING RELATION ON PATTERNS OF INVARIANT SETS
AND REDUCTIONS OF INTERVAL MAPS

JIE-HUA MAI AND SONG SHAO

Abstract. Patterns of invariant sets of interval maps are the equivalence classes of invariant sets under order-preserving conjugacy. In this paper we study forcing relations on patterns of invariant sets and reductions of interval maps. We show that for any interval map $f$ and any nonempty invariant set $S$ of $f$ there exists a reduction $g$ of $f$ such that $g|_S = f|_S$ and $g$ is a monotonic extension of $f|_S$. By means of reductions of interval maps, we obtain some general results about forcing relations between the patterns of invariant sets of interval maps, which extend known results about forcing relations between patterns of periodic orbits. We also give sufficient conditions for a general pattern to force a given minimal pattern in the sense of Bobok. Moreover, as applications, we give a new and simple proof of the converse of the Sharkovskii Theorem and study fissions of periodic orbits, entropies of patterns, etc.

1. Introduction

1.1. Background and preliminaries. In this paper we study the forcing relation on patterns of line systems and reductions of interval maps. An interval map is a continuous map from an interval to itself. A line system is a pair $(X, \psi)$, where $X$ is a nonempty bounded subset of $\mathbb{R}$, $\psi$ is a continuous map from $X$ to $X$, and $\psi$ can be extended to an interval map, that is, there exists an interval map $f : I \to I$ such that $X \subset I$ and $f|_X = \psi$. For any interval map $g : J \to J$ and any nonempty invariant set $Y$ of $g$ (i.e. $g(Y) \subset Y$), the pair $(Y, g|_Y)$ is called a subsystem of $(Y, g)$. Hence, a pair $(X, \psi)$ is a line system if and only if it is a subsystem of some interval map, and a line system can be regarded as a nonempty invariant set of some interval map. Partitioning all line systems by an “order-preserving” relation (the definition will be given below), we obtain various equivalence classes, which are called patterns of these line systems.

Every interval map has infinitely many subsystems. So there is a natural question: if one knows that an interval map has some subsystem, then what can one say about other subsystems of this map? If one confines his attention to periodic systems, then there are rich results on this question. They are included in the theory of forcing relations on patterns of periodic orbits [1, 3, 9, 24].

One uses $\mathbb{R}$ ($\mathbb{N}$ and $\mathbb{Z}$ respectively) to denote the set of the real numbers (the natural numbers and integers respectively), and denote $\mathbb{Z}_n = \{1, 2, \ldots, n\}$ for each $n \in \mathbb{N}$. Let $P = \{p_1, p_2, \ldots, p_n\} \subset \mathbb{R}$ and $\psi : P \rightarrow P$. Then $(P, \psi)$ is a periodic orbit (or a cycle) if $\psi$ is a cyclic permutation of $P$. Two periodic orbits $(P, \psi)$, $(Q, \xi)$ are equivalent if there exists an order-preserving bijection $h : P \rightarrow Q$ such that $h \circ \psi = \xi \circ h$, or $h \psi = \xi h$ for short. An equivalence class of this relation will be called a pattern. If $A$ is a pattern and $(P, \psi) \in A$, then one says that the cycle $(P, \psi)$ has a pattern $A$ (or $P$ is a representative of $A$) and one uses the symbol $[(P, \psi)]$ to denote the pattern $A$.

There is another equivalent way to define the pattern of periodic orbits. Let $(P, \psi)$ be a periodic orbit and $P = \{p_1 < p_2 < \ldots < p_n\}$. Then the pattern of $(P, \psi)$ is defined to be a cyclic permutation $\theta$ of $\mathbb{Z}_n$ which satisfies $\psi(p_i) = p_{\theta(i)}$ for $i = 1, 2, \ldots, n$. It is easy to see that these two definitions are equivalent.

A map $f : I \rightarrow I$ has a cycle $(P, \psi)$ if $P \subset I$ and $f|_P = \psi$, and one says that $f$ exhibits the pattern $[(P, \psi)]$. A map $f$ is called a monotonic extension of $P$ if it is monotone between consecutive elements of $P$ and constant to the left of the leftmost and to the right of the rightmost of $P$. Now one can define a forcing relation between patterns: A pattern $A$ forces a pattern $B$ if each interval map exhibiting $A$ also exhibits $B$.

One important result is that the forcing relation on periodic patterns is a partial order relation [1, 2]. There is also a convenient way to decide the forcing relation on two patterns: let $(P, \psi)$ be a cycle and $B$ a pattern; then $[(P, \psi)]$ forces $B$ if and only if there is a monotonic extension of $(P, \psi)$ which exhibits pattern $B$ [1, 24].

In the theory of discrete dynamical systems, periodic orbits play a very important role. The notion of pattern and forcing relations is the key to the problem of coexistence of various types of cycles for a given map. If one knows which patterns are forced by a given pattern $A$, then one has enormous information about the structure of an interval map with cycle of pattern $A$. Unfortunately, the forcing relation is rather complicated. Therefore it makes sense to consider notation weaker than patterns. This limits the information we get, but makes it easier to obtain it. One such notion is a period. The Sharkovskii Theorem gives the forcing relation among periods. This is a linear ordering, so the characterization of all the periods forced by the given one is simple. Now we state the Sharkovskii Theorem briefly.

Let $I = [a, b]$ be an interval and $C^0(I)$ be the set of all continuous maps from $I$ to itself. For any $f \in C^0(I)$ and $x \in I$, denote $O(x) = O(x, f) = \{x, f(x), f^2(x), \ldots\}$ and $O_n(x) = O_n(x, f) = \{x, f(x), \ldots, f^n(x)\}$. $O(x, f)$ is called an orbit of $f$. A point $x \in I$ is called a periodic point of $f$ with period $n$ if $f^n(x) = x$ and $f^k(x) \neq x$ for $1 \leq k < n$. Denote by $P_n(f)$ the set of all periodic points of $f$ with period $n$ and let $P(f) = \bigcup_{n=1}^{\infty} P_n(f)$. Write

$$
F_n(I) \equiv F(I, n) = \{f \in C^0(I) : P_n(f) \neq \emptyset\}.
$$

For any $m, n \in \mathbb{N}$, we say that $m$ forces $n$ and write $m \leq n$ if $F_m(I) \subset F_n(I)$. In 1964, Sharkovskii discovered the following striking theorem.

**Theorem 1.1.** $3 < 5 < 7 < \ldots < 6 < 10 < 14 < \ldots < 12 < 20 < 28 < \ldots < 8 < 4 < 2 < 1$.

The original proof of Theorem [1] was given in [25]. Besides this proof, some authors also gave variants of proofs; see [11, 16, 20, 22, 26], etc. In most of these proofs, the idea of Straffin [27] concerning directed graphs was adopted.
As a supplement of Theorem 1.1 Sharkovski\'i\' also proved the following theorem, which is called the converse of Sharkovski\'i\'s Theorem by Elaydi [19].

**Theorem 1.2.** For any \( m, n \in \mathbb{N} \) with \( m \neq n \), if \( m < n \), then \( F_n(I) - F_m(I) \neq \emptyset \). Moreover, let

\[
F(I, 2^\infty) = \bigcap_{k=0}^{\infty} F(I, 2^k), \quad \Phi(I, 2^\infty) = \bigcup \{ F_n(I) : n \in \mathbb{N} - \{ 2^k - 1 : k \in \mathbb{N} \} \}.
\]

Then \( F(I, 2^\infty) - \Phi(I, 2^\infty) \neq \emptyset \).

Unfortunately, the classification of cycles by periods only is very coarse. Knowing only periods of cycles is much less than knowing their patterns. Later some other possible choices were discovered ([5], [6], [15], etc.). This gives a better classification than just by periods, and on the other hand, it admits a full description of possible sets of types. Please refer to related references for more details.

In this paper, though we will discuss periodic patterns frequently, our main purpose is to study the forcing relation under more general situations. In [13], the author generalized the forcing relation to minimal piecewise monotone patterns. Let \( \mathcal{M} \) be the set of pairs \( (X, g) \) such that \( X \subset \mathbb{R} \) is compact, \( g: X \to X \) is continuous, \( g \) is minimal on \( X \) and has a piecewise monotonic extension to the convex hull of \( X \). Two pairs \( (X, g), (Y, f) \) from \( \mathcal{M} \) are equivalent if the map \( h: \mathcal{O}(\min X, g) \to \mathcal{O}(\min Y, f) \), defined by \( h(g^m(\min X)) = f^m(\min Y) \) for each \( m \geq 0 \), is increasing on \( \mathcal{O}(\min X, g) \). An equivalence class of this relation is defined to be a minimal pattern. In [13], the author showed that the forcing relation on minimal piecewise monotone patterns is a partial ordering.

### 1.2. Main results of the paper.

In this paper we study forcing relations on patterns of invariant sets of interval maps, and our viewpoint is different from [13] (also we do not assume that the maps considered are piecewise monotone).

Let \( \Psi \) be the set of all line systems \( (X, \psi) \). Let \( (X, \psi), (Y, \xi) \in \Psi \). We say that \( (X, \psi) \) and \( (Y, \xi) \) have the same pattern (denoted by \( (X, \psi) \approx (Y, \xi) \)) if there exists an order-preserving bijection \( h: X \to Y \) such that \( h\psi = \xi h \), and such a bijection \( h \) is called an order-preserving conjugacy from \( \psi \) to \( \xi \). Denote by \( \Psi^* \) the set of equivalence classes in \( \Psi \) under the equivalence relation \( \approx \), i.e. \( \Psi^* = \Psi / \approx \). Then \( \Psi^* \) can be regarded as the set of patterns of invariant sets of interval maps. Unlike patterns of periodic orbits and minimal sets, the forcing relation on \( \Psi^* \) is not a partial ordering any more (see Examples 4.5, 4.7).

Let \( A, B \in \Psi^* \) be two patterns. We say that \( A \) forces \( B \) if every interval map having an invariant set with the pattern \( A \) also has an invariant set with the pattern \( B \). Our aim is to give some conditions under which \( A \) can force \( B \). For this purpose, we develop a tool known as the reduction of continuous maps.

Let \( J, I \) be compact intervals with \( J \subset I \), \( f \in C^0(I) \) and \( g \in C^0(J) \). Write \( \Delta(f, g) = \{ x \in J : g(x) \neq f(x) \} \). \( g \) is called a reduction of \( f \) if each point \( x \in \Delta(f, g) \) is wandering under \( g \) and \( g \) is constant on every connected component of \( \Delta(f, g) \). About the reduction we have the following result:

**Theorem 2.8.** For any \( f \in C^0(I) \) and any nonempty invariant set \( S \) of \( f \) there exists a reduction \( g \in C^0(J) \) of \( f \) with \( J = [\inf S, \sup S] \) such that \( g|_S = f|_S \) and \( g \) is monotonic on each connected component of \( J - S \).
By means of reductions of maps, we obtain several general results about the forcing relation between the patterns of invariant sets on intervals. For example, we give a characterization of the forcing relation between patterns in the absence of companionate orbits (see Definition 4.13):

**Theorem 4.14.** Let $X \subset \mathbb{R}$ be compact and $(X, \psi), (Z, \xi) \in \Psi$. Suppose $\xi$ has no companionate orbits. Then $[(X, \psi)]$ forces $[(Z, \xi)]$ if and only if there exists a monotonic extension of $(X, \psi)$ which exhibits $\xi$.

For some special patterns, we can weaken the conditions. For example, for the case of periodic patterns, we have

**Theorem 5.2.** Let $(X, \psi)$ be a compact line system. Then $[(X, \psi)]$ forces a periodic pattern $[(P, \theta)]$ if and only if there exists a monotonic extension of $\psi$ which has a periodic orbit of pattern $\theta$.

As for nonperiodic minimal patterns, we have a sufficient condition for a general pattern to force a given minimal pattern:

**Theorem 5.8.** Let $(W, \varphi)$ be a compact line system, and let $(X, \psi)$ be a minimal line system but not periodic. If there exists a monotonic extension $f$ of $(W, \varphi)$ exhibiting $(X, \psi)$, then each interval map exhibiting $(W, \varphi)$ has a minimal subset which is equivalent to $(X, \psi)$ in the sense of Bobok.

As applications of the idea of reductions of interval maps, we study periodic patterns and give a new approach to Theorem 1.2. Also we apply the results on forcing relations that we built to study fissions of periodic orbits, etc. For example, we define $h^*(X, \psi) = \inf\{h(I, f) : f \in C^0(I) \text{ and } f|_X = \psi\}$, where $X$ is compact and $I = [\inf X, \sup X]$. We show that if $(X, \psi) \approx (Y, \xi)$ with $X, Y$ compact, then $h^*(X, \psi) = h^*(Y, \xi)$ (Corollary 7.4). Hence we can define the topological entropy of a pattern.

1.3. **Organization of the paper.** The paper is organized as follows: In Section 2 we introduce the definition of reductions of interval maps and give some basic properties and results. In particular, we will prove Theorem 2.8. In Section 3, as applications of the tool developed in Section 2, we give some results on patterns of periodic orbits. In particular, we give a new and simple proof of Theorem 1.2. Sections 4 and 5 are the bulk of the paper, where we study the forcing relation on invariant sets carefully. In Section 4 we give some general conditions under which one pattern can force another one, and in Section 5 we discuss the periodic and nonperiodic minimal patterns. In Section 6 we use the results developed in Section 4 to study the fissions of periodic orbits, etc. Finally, we study the entropy of patterns in the last section.

2. Reductions of interval maps

In this section we introduce the concept of reductions of interval maps, and we show that for any $f \in C^0(I)$ and any nonempty invariant set $S$ of $f$, there exists a reduction of $f$ preserving $S$.

2.1. Notation. For any \( \{r, s\} \subset \mathbb{R} \) with \( r < s \), write \( [r; s] = [s; r] = [r, s] \), and \( [r; r] = \{r\} \). For any \( \{a, b\} \subset \mathbb{R} \), write \( (a; b) = [b; a) = [a; b) - \{a\}, \) and \( (a; b) = (b; a) = (a; b) - \{b\} \). For any nonempty bounded set \( X \subset \mathbb{R} \), let \( L[X] \) denote the closed convex hull of \( X \) in \( \mathbb{R} \), i.e.,

\[
L[X] = [\inf X, \sup X],
\]

and let

\[
l(X) = \sup X - \inf X.
\]

The interior, closure and boundary of \( X \) in \( \mathbb{R} \) are denoted by \( \overset{o}{X} \), \( \overline{X} \) and \( \partial X \), respectively.

Let \( X \) be a topological space and \( f : X \rightarrow X \) be a continuous map. A point \( x \in X \) is called a **recurrent point** of \( f \) if for any neighborhood \( U \) of \( x \) and any \( m \in \mathbb{N} \) there exists \( n > m \) such that \( f^n(x) \in U \). A point \( x \in X \) is **nonwandering** if for every neighborhood \( U \) of \( x \), \( f^n(U) \cap U \neq \emptyset \) for some \( n \in \mathbb{N} \). Denote respectively by \( R(f) \) and \( \Omega(f) \) the set of all recurrent and nonwandering points of \( f \). It is clear that both \( R(f) \) and \( \Omega(f) \) are invariant sets of \( f \).

2.2. Reductions of interval maps. Let \( I = [a, b] \) and \( f \in C^0(I) \). A closed interval \( J \subset I \) is called a **level interval** of \( f \) if \( f|J \) is constant.

**Definition 2.1.** Let \( I, J \) be compact intervals with \( J \subset I \) and \( f \in C^0(I), g \in C^0(J) \). Set

\[
\Delta(f, g) = \{y \in J : g(y) \neq f(y)\}.
\]

\( g \) is called a **reduction** of \( f \) if the following conditions are satisfied:

(a) \( \Delta(f, g) \cap \Omega(g) = \emptyset \);

(b) \( g \) is constant on every connected component of \( \Delta(f, g) \).

It is easy to see that \( \Delta(f, g) \) is an open set relative to the topology of \( J \), and if \( \Delta(f, g) \cap \partial J = \emptyset \), then every connected component of \( \Delta(f, g) \) is an open interval. Note that in Definition 2.1 we do not insist that \( J \neq I \) or \( g \neq f \). Thus \( f \) itself is also a reduction of \( f \).

We now exhibit some basic properties on reductions of interval maps.

**Lemma 2.2.** Let \( J \subset I \) be intervals and \( g \in C^0(J) \) be a reduction of \( f \in C^0(I) \). Then

(i) \( g|\Omega(g) = f|\Omega(g) \);

(ii) \( R(g) \subset R(f) \), and \( P_n(g) \subset P_n(f) \) for all \( n \in \mathbb{N} \);

(iii) for any interval \( K \subset J \), if \( f|K \) is increasing (decreasing, constant respectively), then \( g|K \) is increasing (decreasing, constant respectively);

(iv) \( l(g(K)) \leq l(f(K)) \), for any interval \( K \subset J \);

(v) \( \Omega(g) \subset \Omega(f) \).

**Proof.** It is easy to verify (i)-(iv) by the definition. Now we show (v). Consider any \( x \in \Omega(g) \). For any \( \varepsilon \)-neighborhood \( U \) of \( x \) in \( J \), there exist \( w \in U \) and \( m \in \mathbb{N} \) such that \( g^m(w) \in U \). If \( \{w, g(w), \ldots, g^{m-1}(w)\} \cap \Delta(f, g) \neq \emptyset \), then there exists an \( n \in \{0, 1, \ldots, m - 1\} \) such that \( g^n(w) \in \Delta(f, g) \) and \( g^j(w) \notin \Delta(f, g) \) for all \( j \in \{n + 1, \ldots, m - 1\} \). Let \( K_n \) be the connected component of \( \Delta(f, g) \) containing \( g^n(w) \). Then \( g|K_n \) is constant. By (a) of Definition 2.1 \( g^m(x) \notin K_n \). Hence there is
a $u_n \in [x; w)$ such that $g^n(u_n) \in \overline{T_n - K_n} \subset J - \Delta(f, g), g^j(u_n) = g^{i-n}(g^n(u_n)) = g^{i-n}(g^n(w)) = g^j(w) \notin \Delta(f, g)$ for $j \in \{n + 1, \ldots, m - 1\}$, and $g^m(u_n) = g^m(w) \in U$. If it is still the case that $\{u_n, g(u_n), \ldots, g^{m-1}(u_n)\} \cap \Delta(f, g) \neq \emptyset$, then one can also find a $k \in \{0, 1, \ldots, n - 1\}$ and an $u_k \in [x; u_n)$ such that $\{g^j(u_k) : j = k, k + 1, \ldots, m - 1\} \cap \Delta(f, g) = \emptyset$ and $g^m(u_k) = g^m(w) \in U$. Thus there must exist a $u = u_0 \in [x; w)$ such that $\{u, g(u), \ldots, g^{m-1}(u)\} \cap \Delta(f, g) = \emptyset$ and $g^m(u) = g^m(w) \in U$. By (2.1), one has $f^m(u) = g^m(u) \in U$. This implies $x \in \Omega(f)$, and hence $\Omega(g) \subset \Omega(f)$.

Lemma 2.3. Let $g$ be a reduction of $f$, and let $h$ be a reduction of $g$. Then $h$ is a reduction of $f$.

Proof. Note that $\Delta(f, h) \subset \Delta(f, g) \cup \Delta(g, h)$. By Definition 2.1(a) and Lemma 2.2(v), $\Delta(f, h) \cap \Omega(h) \subset (\Delta(f, g) \cup \Delta(g, h)) \cap \Omega(h) \subset (\Delta(f, g) \cap \Omega(g)) \cup (\Delta(g, h) \cap \Omega(h)) = \emptyset$. By Definition 2.1(b) and Lemma 2.2(iii), $h$ is constant on every connected component of $\Delta(g, h)$ and of $\Delta(f, g)$. Thus $h$ is a reduction of $f$.

Proposition 2.4. Let $I_0 \supset I_1 \supset I_2 \supset \ldots$ and $J = \bigcap_{n=0}^\infty I_n$ be compact intervals and let $f_{n+1} \in C^0(I_{n+1})$ be a reduction of $f_n \in C^0(I_n)$ for $n = 0, 1, 2, \ldots$. Then $f_0|J, f_1|J, f_2|J, \ldots$ converges uniformly to a map $g \in C^0(J)$, which is also a reduction of $f_0$.

Proof. By Lemma 2.3, each $f_n$ is a reduction of $f_0$. Suppose $J = [c, d]$. Let $P_1 = \bigcap_{n=0}^\infty P_1(f_n)$. For $n \geq 0$, $P_1(f_n)$ is a nonempty closed set. By Lemma 2.2(ii), $P_1(f_{n+1}) \subset P_1(f_n)$. Thus $P_1$ is nonempty. By Lemma 2.2(i), $f_0|P_1 = f_1|P_1 = f_2|P_1 = \ldots$. Take a point $e \in P_1$. For any $x \in [c, e]$ (resp. $x \in [e, d]$), let $Y_{x, n}$ be the connected component of $f_n^{-1}(f_n(x)) \cap [c, e]$ (resp. $f_n^{-1}(f_n(x)) \cap [e, d]$) containing $x$, and let $y_{x, n} = \max Y_{x, n}$ (resp. $y_{x, n} = \min Y_{x, n}$). It follows from (b) of Definition 2.1 that $y_{x, n} \notin \Delta(f_0, f_n)$. Hence $f_n(x) = f_n(y_{x, n}) = f_0(y_{x, n})$. By Lemma 2.2(iii), $Y_{x, 0} \subset Y_{x, 1} \subset Y_{x, 2} \subset \ldots$. Thus $y_{x, 0}, y_{x, 1}, y_{x, 2}, \ldots$ is a monotonic sequence. Let $y_x = \lim_{n \to \infty} y_{x, n}$. Then $\lim_{n \to \infty} f_n(x) = \lim_{n \to \infty} f_0(y_{x, n}) = f_0(y_x)$.

Define $g : J \to J$ by

$$g(x) = f_0(y_x), \quad \text{for any } x \in J.$$

Then $f_0|J, f_1|J, f_2|J, \ldots$ converges pointwisely to $g$. For any closed interval $K \subset J$, it follows from Lemma 2.2(iv) that

$$l(f_0(K)) \geq l(f_1(K)) \geq l(f_2(K)) \geq \ldots.$$

Thus $\{f_n|J : n = 0, 1, 2, \ldots\}$ is an equicontinuous family of maps, and hence $f_0|J, f_1|J, f_2|J, \ldots$ converges uniformly to $g$. This implies that $g$ is continuous.

For any $x \in \Delta(f_0, g)$, there exists an $m \geq 1$ such that $x \in \Delta(f_0, f_m)$. By Definition 2.1, there is an open $\varepsilon$-neighborhood $U_x$ of $x$ in $J$ such that $f_n(U_x) = \{f_m(x)\}$ and $U_x \cap \Omega(f_m) = \emptyset$. For all $n \geq m$, by (iii) and (v) of Lemma 2.2, one gets $f_n(U_x) = \{f_m(x)\}$ and $U_x \cap \Omega(f_n) = \emptyset$, which imply that $g(U_x) = \{g(x)\}$ and $\mathcal{O}(f_m(x), f_n) \cap U_x = \emptyset$. Since $f_m$ converges uniformly to $g$ as $n \to \infty$, one has $\mathcal{O}(g(x), g) \cap U_x = \emptyset$, which implies that $x \notin \Omega(g)$. Thus $g$ satisfies the conditions (a) and (b) in Definition 2.1 for $f = f_0$, and hence $g$ is a reduction of $f_0$. This completes the proof of Proposition 2.4. □
2.3. **Normal reduction of $f$ preserving $S$.** Now we are going to show that for any $f \in C^0(I)$ and any invariant set $S$ of $f$, there exists a reduction of $f$ preserving $S$. In fact we can say more.

**Definition 2.5.** Let $f \in C^0(I)$, and let $S$ be a nonempty invariant set of $f$. A map $g \in C^0(L(S))$ is called a normal reduction of $f$ preserving $S$ if $g$ is a reduction of $f$, $g|_S = f|_S$, and $g$ is monotonic on every connected component of $L(S) - S$.

**Remark 2.6.** Note that, for any $g \in C^0(L(S))$ and any $x \in L(S)$, $g_{\{x\}}$ is monotonic. Thus, $g$ is monotonic on every connected component of $L(S) - S$ if and only if $g$ is monotonic on every connected component of $L(S) - \bar{S}$, and hence, $g$ is a normal reduction of $f$ preserving $S$ if and only if $g$ is a normal reduction of $f$ preserving $\bar{S}$.

**Example 2.7.** Let $f : [0, 1] \to [0, 1]$ be a piecewise linear map whose graph is as in Figure 1. It is clear that $S = \{0, 1/2, 1\}$ is an invariant set of $f$. Then as in Figure 1, $g$ is a normal reduction of $f$ preserving $S$.

![Figure 1](image)

**The main result of this part is the following:**

**Theorem 2.8.** Let $f \in C^0(I)$ and let $S$ be a nonempty invariant set of $f$. Then there exists a normal reduction of $f$ preserving $S$.

To prove Theorem 2.8 one needs some preparations.

**Definition 2.9.** Let $I = [a, b]$, $f \in C^0(I)$ and $S$ be a nonempty invariant set of $f$. An interval $J = [v, y]$ is called a pseudo-levelable interval of $(S, f)$ if $J \subset L(S), J \cap S = \emptyset, f(v) = f(y)$ and $l(f(J)) > 0$. A pseudo-levelable interval $J = [v, y]$ of $(S, f)$ is said to be levelable if $O(v) \cap J = \emptyset$.

Write

\begin{align}
\lambda(S, f) &= \sup\{0\} \cup \{l(f(J)) : J \text{ is a levelable interval of } (S, f)\}, \\
\mu(S, f) &= \sup\{0\} \cup \{l(f(J)) : J \text{ is a pseudo-levelable interval of } (S, f)\}.
\end{align}

A levelable interval $J$ of $(S, f)$ is said to be maximal if $l(f(J)) = \lambda(S, f)$ and $l(J) = \max\{l(K) : K \text{ is a levelable interval of } (S, f) \text{ with } l(f(K)) = \lambda(S, f)\}$. Similarly, one can define maximal pseudo-levelable intervals of $(S, f)$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Obviously, if $\lambda(S,f) > 0$ (resp. $\mu(S,f) > 0$), then there exists a maximal levelable (resp. maximal pseudo-levelable) interval of $(S,f)$.

**Remark 2.10.** From Definition 2.9 we see that, for any $f \in C^0(I)$ and any nonempty invariant set $S$ of $f$, an interval $J \subset L(S)$ is a levelable (resp. pseudo-levelable) interval of $(S,f)$ if and only if $J$ is a levelable (resp. pseudo-levelable) interval of $(\overline{S},f)$. Hence, we have $\lambda(S,f) = \lambda(\overline{S},f)$ and $\mu(S,f) = \mu(\overline{S},f)$.

One can get the following two lemmas readily.

**Lemma 2.11.** Let $S$ be a nonempty invariant set of $f \in C^0(I)$. Then $\mu(S,f) = 0$ if and only if $f$ is monotonic on every connected component of $L(S) - S$.

**Lemma 2.12.** Let $S$ be a nonempty invariant set of $f \in C^0(I)$, and let $J = [v,y]$ be a levelable interval of $(S,f)$. Define $\varphi : I \to I$ by

$$
\varphi(x) = \begin{cases} 
  f(x), & \text{if } x \in I - J; \\
  f(v), & \text{if } x \in J.
\end{cases}
$$

Then $\varphi$ is a reduction of $f$, and $\overline{J} \cap \Omega(\varphi) = \emptyset$. (See Figure 2.)

![Figure 2](image-url)

**Definition 2.13.** The map $\varphi : I \to I$ defined in Lemma 2.12 is called a basic reduction of $f$ by leveling $J$.

**Lemma 2.14.** Let $J \subset I$ be compact intervals, $f \in C^0(I)$ and $g \in C^0(J)$. Suppose $S$ is a nonempty invariant set of $g$ and $g|_S = f|_S$. If $g$ is a reduction of $f$, then $\mu(S,g) \leq \mu(S,f)$.

**Proof.** Assume $K = [v,y]$ is a pseudo-levelable interval of $(S,g)$. Then $g(v) = g(y)$. Let $K_v$ (resp. $K_y$) be the connected component of $g^{-1}([g(v)]$ containing $v$ (resp. $y$). Suppose $\max K_v = v_1$, $\min K_y = y_1$. Then by Definition 2.11(b), one
has \( f(v_1) = g(v_1) = g(v) = g(y) = g(y_1) = f(y_1) \), and by Lemma 2.2 iv one has \( l(g([v, y])) = l(g([v_1, y_1])) \leq l(f([v_1, y_1])) \). Thus \([v_1, y_1]\) is a pseudo-levelable interval of \( (S, f)\), and from [2.3] it follows that \( \mu(S, g) \leq \mu(S, f) \). \( \square \)

**Lemma 2.15.** Let \( S \) be a nonempty invariant set of \( f \in C^0(I) \). Then

\[
\mu(S, f) \geq \lambda(S, f) \geq \mu(S, f)/4.
\]

**Proof.** It is clear that \( \mu(S, f) \geq \lambda(S, f) \). It is left to show that \( \lambda(S, f) \geq \mu(S, f)/4 \). Since \( \mu(S, f) = 0 \) implies \( \lambda(S, f) = 0 \), one may assume that \( \mu(S, f) > 0 \). Let \( J = [v; y] \) be a pseudo-levelable interval of \((S, f)\) satisfying \( l(f(J)) = \mu(S, f) \).

Take \( u \) and \( v_1 \in J \) such that \( f(u) = \max(f(J)) \) and \( f(v_1) = \min(f(J)) \). Then \( f(u) - f(v_1) = l(f(J)) \). By symmetry, one may assume \( f(u) - f(y) \geq l(f(J))/2 \).

Let \( (z; z_1) \) be the connected component of \( L(S) - S \) containing \( J \). One may assume \( f(z_1) \geq f(z) \) and \( v \in [z; y) \).

If \( f(u) \geq f(z_1) \), then there exists \( w \in [z; u) \) such that \( f(w) = f(z_1) \). Since \([w; z_1]\) is a levelable interval of \((S, f)\), \( \lambda(S, f) \geq l(f([w; z_1])) \geq f(u) - f(y) \geq l(f(J))/2 = \mu(S, f)/2 \).

If \( f(y) \leq f(z) \), then there exists \( z_2 \in [y; z_2] \) such that \( f(z_2) = f(z) \). Since \([z; z_2]\) is a levelable interval of \((S, f)\), \( \lambda(S, f) \geq l(f([z; z_2])) \geq l(f(J)) = \mu(S, f) \).

If \( f(u_1) \leq f(z) < f(y) \) and \( u_1 \in (u; y) \), then there exists \( z_3 \in [u_1; y) \) such that \( f(z_3) = f(z) \) and one also has \( \lambda(S, f) \geq l(f([z; z_3])) \geq f(u) - f(u_1) = \mu(S, f) \).

In the following we assume

\[
f(z) < f(v) = f(y) < f(u) < f(z_1)
\]

and

\[
u_1 \in [v; u) \quad \text{or} \quad u_1 \in (u; y) \quad \text{and} \quad f(u_1) > f(z).
\]

Then there exist \( w_1 \in (y; z_1) \), \( y_1 \in (u; w_1) \) and \( v_1 \in (z; u) \) such that

\[
f(w_1) = f(u), \quad f(y_1) = f(v_1) = \min(f([u; w_1]))
\]

and

\[
f([v_1; u]) = f([u; y_1]) = f([y_1; w_1]) = [f(y_1), f(u)].
\]

Note that we have

\[
z < v_1 < u < y_1 < w_1 < z_1 \quad \text{or} \quad z > v_1 > u > y_1 > w_1 > z_1.
\]

If \( \mathcal{O}(u) \cap (u; w_1) = \emptyset \), then \([u; w_1]\) is a levelable interval of \((S, f)\) and \( \lambda(S, f) \geq l(f([u; w_1])) \geq f(u) - f(y) \geq \mu(S, f)/2 \). If \( \mathcal{O}(u) \cap (u; w_1) \neq \emptyset \), then there exist \( j \in \mathbb{N} \) such that \( f^j(u) \in (u; w_1) \). This implies \( P(f) \cap [u; w_1] \supseteq P(f) \cap (u; w_1) \neq \emptyset \) for any \( x \in P(f) \), let \( p(x) \) be the period of \( x \) under \( f \). Take \( x_0 \in P(f) \cap [v_1; w_1] \) such that

\[
p(x_0) = \min\{p(x) : x \in P(f) \cap [v_1; w_1]\}.
\]

Suppose \( p(x_0) = k \). Then \( k \leq j \). Take \( x_1 \in [v_1; u) \) and \( x_2 \in [y_1; w_1] \) such that \( f(x_1) = f(x_2) = f(x_0) \) and \( f^{-1}(f(x_0)) \cap [v_1; w_1] \subseteq [x_1; x_2] \). Then \( \mathcal{O}(x_0) - \{x_0\} \cap [x_1; x_2] = \emptyset \) since otherwise there would be a point \( y_0 \in P(f) \cap (x_1; x_2) \) with \( p(y_0) \leq k - 1 \), which contradicts (2.4).

If \( x_0 \in [v_1; u) \), then \([x_0; x_2]\) is a levelable interval of \((S, f)\) and one has \( \lambda(S, f) \geq l(f([x_0; x_2])) = f(u) - f(y_1) \geq f(u) - f(y) \geq \mu(S, f)/2 \). If \( x_0 \in [y_1; w_1] \), then one
also has \( \lambda(S, f) \geq l(f([x_1; x_0])) \geq f(u) - f(y_1) \geq \mu(S, f)/2 \). If \( x_0 \in [u; y_1] \), then one still has

\[
\left\{
\begin{array}{ll}
\lambda(S, f) \geq l(f([x_0; x_2])) \geq f(x_0) - f(y_1) \geq \mu(S, f)/4 & \text{if } f(x_0) \geq [f(u) + f(y_1)]/2; \\
\lambda(S, f) \geq l(f([x_1; x_0])) \geq f(u) - f(x_0) \geq \mu(S, f)/4 & \text{if } f(x_0) \leq [f(u) + f(y_1)]/2.
\end{array}
\right.
\]

The proof of Lemma 2.15 is completed. \( \square \)

Now it is time to prove Theorem 2.8.

Proof of Theorem 2.8. First, let \( f_0 = f \). For \( k \geq 0 \), suppose \( f_k \in C^0(I) \) has been defined. If \( \lambda(S, f_k) = 0 \), then set \( J_k = \emptyset \) and \( f_{k+1} = f_k \). If \( \lambda(S, f_k) > 0 \), then take a maximal levelable interval \( J_k = [v_k; y_k] \) of \( (S, f_k) \) and let \( f_{k+1} \in C^0(I) \) be the basic reduction of \( f_k \) by leveling \( J_k \). Continuing this process, one has sequences \( \{f_n\}_{n=0}^{\infty} \) and \( \{J_n\}_{n=0}^{\infty} \).

Claim. \( \lim_{k \to \infty} \lambda(S, f_k) = 0 \).

Proof of Claim. If the claim does not hold, then there exist \( \varepsilon > 0 \) and infinitely many positive integers \( k_1 < k_2 < k_3 < \ldots \) such that

\[
l(f_k(J_{k_n})) = \lambda(S, f_k) \geq \varepsilon \quad \text{for all } n \geq 1,
\]

\[
\lim_{n \to \infty} v_k = w \quad \text{and} \quad \lim_{n \to \infty} y_k = z \quad \text{for some } w, z \in L(S).
\]

Since \( f \) is uniformly continuous, there is \( \delta = \delta(\varepsilon) > 0 \) such that

\[
l(f(J)) < \varepsilon/3 \quad \text{for every interval } J \subset I \text{ with } l(J) < \delta.
\]

By (2.5), there exists \( m > 1 \) such that \( |v_{k_{m+1}} - v_{k_m}| < \delta \) and \( |y_{k_{m+1}} - y_{k_m}| < \delta \). According to Lemma 2.3, Lemma 2.2(iv) and (2.6) one has that

\[
l(f_{k_{m+1}}(J_{k_{m+1}})) \leq l(f([v_{k_{m+1}}; v_{k_m}])) + l(f_{k_{m+1}}(J_{k_m})) + l(f([y_{k_{m+1}}; y_{k_m}]))
\]

\[
< \varepsilon/3 + 0 + \varepsilon/3 < \varepsilon.
\]

But this contradicts (2.5). This completes the proof of the claim.

By the above claim and Lemma 2.15 one has \( \lim_{n \to \infty} \mu(S, f_k) = 0 \). By Proposition 2.4 \( f_0, f_1, f_2, \ldots \) converges uniformly to a map \( g \in C^0(I) \), which is a reduction of \( f_n \) for all \( n \geq 0 \). Clearly, \( S \) is still an invariant set of \( g \), and \( g|_S = f|_S \). By Lemma 2.14 one has \( \mu(S, g) = 0 \). Put \( \varphi = g|_L(S) \). Then \( \varphi \in C^0(L(S)) \) is a reduction of \( f \), \( \varphi|_S = g|_S = f|_S \), and \( \mu(S, \varphi) = \mu(S, g) = 0 \). By Lemma 2.6, \( \varphi \) is monotonic on every connected component of \( L(S) - S \). Thus \( \varphi \) is a normal reduction of \( f \) preserving \( S \). The proof of Theorem 2.8 is completed. \( \square \)

3. Some results on periodic patterns

As applications of the idea of reductions of interval maps, in this section we study patterns of periodic orbits. In particular, we will give a new and simple proof of the converse of Sharkovskii’s Theorem (Theorem 1.2). Usually, the proof of Theorem 1.2 is obtained by constructing some concrete examples (see [26, 18]). But here we use the method of reductions of maps.
3.1. Relation $\triangleleft$ on $\mathbb{N}$. First recall some notation. Let $I = [a, b]$ and $F_n(I)$ be as in \([1,1]\). For any $m, n \in \mathbb{N}$ with $m \neq n$, write $m \triangleleft n$ or $n \triangleright m$ if $F_m(I) \subset F_n(I)$. Then one obtains a relation $\triangleleft$ on $\mathbb{N}$. Write

$$F_n^\ast(I) \equiv F^\ast(I, n) = F_n(I) - \bigcup \{ F_m(I) : m \in \mathbb{N} \text{ and } m \triangleleft n \}.$$ 

The main results of this part are Theorem 3.4 and Theorem 3.5. To prove them we need some notions and lemmas. For any finite set $T$, let $|T|$ denote the cardinality of $T$.

**Definition 3.1.** Let $f \in C^0(I)$ and $X = \{x_1 < x_2 < \ldots < x_n\}$ be a periodic orbit of $f$ with period $n \geq 1$. $X$ is said to be in an odd (resp. even) state under $f$ if for each $i \in \mathbb{Z}_n$ there exists an open interval $J_i$ with $x_i \in J_i \subset I$ such that $f|_{J_i}$ is monotonic but not constant and the cardinality $|\{ i \in \mathbb{Z}_n : f|_{J_i} \text{ is decreasing}\}|$ is odd (resp. even).

**Lemma 3.2.** Let $f \in C^0(I)$ and $x \in P_n(f), n \geq 1$. Suppose that $O(x)$ is in an odd or even state under $f$. Then for any given integer $k \geq 2$, there exists an open interval $U = U_k$ with $x \in U \subset I$ such that

(i) $U \cap P_k(f) = \emptyset$ for any $i \in \{1, 2, \ldots, kn\} - \{n, 2n\}$.

(ii) If there exists $y \in U \cap P_n(f) - \{x\}$, then $O(x)$ is in an even state under $f$, and $[x; y) \cap \Omega(f) - P_n(f) = \emptyset$.

(iii) If there exists $y \in U \cap P_{2n}(f)$, then $O(x)$ is in an odd state under $f$, $x \in (y; f^n(y))$, and $[y; f^n(y)] \cap \Omega(f) - \{x\} - P_{2n}(f) = \emptyset$.

**Proof.** Let $O(x) = \{x_1 < x_2 < \ldots < x_n\}$. Let $J_1, J_2, \ldots, J_n$ be as in Definition 3.1. Then there exists an open interval $U = U_k$ with $x \in U \subset I$ such that $\bigcup_{i=1}^{n} f^{i}(U) \subset \bigcup_{i=1}^{n} J_i$, and $\bigcup_{m=0}^{k} f^{m+i}(U) \cap \bigcup_{m=0}^{k} f^{m+i}(U) = \emptyset$ for $0 \leq i < j < n$. Note that $f^{n}|_{U}$ is increasing (resp. decreasing) if $O(x)$ is in an even (resp. odd) state under $f$. It is easy to check that the properties (i)–(iii) hold.

**Lemma 3.3.** If $f \in C^0(I)$ has a periodic orbit $Q$ with period $m$, then for any $n \triangleright m$, $f$ has a periodic orbit of period $n$ contained in $L(Q)$.

**Proof.** Let $g$ be a normal reduction of $f$ preserving $Q$. Since $m \triangleleft n$, $g$ has a periodic orbit $Q'$ with period $n$. Since $g \in C^0(L(Q))$, one has $Q' \subset L(Q)$. Since $g$ is a reduction of $f$, $Q'$ is also a periodic orbit of $f$.

**Theorem 3.4.** For any $f \in C^0(I)$ and $n \in \mathbb{N}$, if $P_n(f) \neq \emptyset$, then there exists a periodic orbit $Q$ of $f$ with period $n$ and a normal reduction $\varphi$ of $f$ preserving $Q$ such that $P_m(\varphi) = \emptyset$ for all $m \triangleleft n$.

**Proof.** Let $Q_0$ be a periodic orbit of $f$ with period $n$, and let $g$ be a normal reduction of $f$ preserving $Q_0$. Then $g$ is piecewise monotonic. Let $S_n(g) = \{ x \in P_n(g) : x = \min \Omega(x, g) \}$ and let $v = \sup S_n(g)$. If $v \in P_n(g)$, take $Q = \Omega(v, g)(= \Omega(v, f))$ and let $\varphi$ be a normal reduction of $g$ preserving $Q$. Then $P_m(\varphi) = \emptyset$ for all $m \triangleleft n$. If not, it follows from Lemma 3.3 that $g$ has a periodic orbit with period $n$ contained in $L(Q)$, which contradicts the definition of $v$.

If $v \notin P_n(g)$, then $v \in P_k(g)$ for some divisor $k$ of $n$. By Lemma 3.2, $\Omega(v, g)$ must be in an odd state under $g$ and $k = n/2$. Choose $y \in S_n(g)$ such that $v - y$ is sufficiently small. Then $[y, v) \cap \Omega(g) = P_n(g)$. Take $Q = \Omega(v, g)$ and let $\varphi$ be a normal reduction of $g$ preserving $Q$. Then we still have $P_m(\varphi) = \emptyset$ for all $m \triangleleft n$. If not, $\varphi$ has a periodic orbit with period $m$ contained in $L(Q)$. Since...
Proof. Let \( \varphi \) by Theorem 3.4 one can construct a map \( g \) and a normal reduction \( \varphi \) (and hence \( g \)) has a periodic orbit with period \( n \) contained in \( \Omega(g) \). Then by Lemma 3.3 \( \varphi \) (and hence \( g \)) has a periodic orbit with period \( n \) contained in \( L(Q) - [y,v] \). Then by Lemma 3.3 \( \varphi \) (and hence \( g \)) has a periodic orbit with period \( n \) contained in \( L(Q) - [y,v] \), which contradicts the definition of \( v \).

By Theorem 3.4 we see that \( F_m(I) \neq F_n(I) \) for all \( m \neq n \in \mathbb{N} \). Moreover we have:

**Theorem 3.5.** Let \( m_1, m_2, m_3, \ldots \) and \( n_1, n_2, n_3, \ldots \) be two infinite sequences of positive integers. Suppose \( m_i < n_j \) for all \( i, j \in \mathbb{N} \). Then

\[
\bigcap_{i=1}^{\infty} F_{m_i}(I) - \bigcup_{j=1}^{\infty} F_{m_j}(I) \neq \emptyset.
\]

Proof. Let \( a_0 = a, a_j = (a_{j-1} + b)/2 \), and \( I_j = [a_{j-1}, a_j] \) for \( j = 1, 2, \ldots \). Then by Theorem 3.4 one can construct a map \( g \in C^0(I) \) such that \( g(I_j) \subset I_j \) and \( g|_{I_j} \in F_{n_j}^*(I_j) \) for all \( j \geq 1 \). Clearly, \( g \in \bigcap_{i=1}^{\infty} F_{m_i}(I) - \bigcup_{j=1}^{\infty} F_{m_j}(I) \).

**3.2. Patterns of periodic orbits.** Now we study patterns of periodic orbits. Denote by \( C_n \) the set of all cyclic permutations of \( \mathbb{Z}_n \) and let

\[
C = \bigcup_{n=1}^{\infty} C_n.
\]

Let \( I = [a, b], f \in C^0(I) \) and \( Q = \{x_1 < x_2 < \ldots < x_n\} \) be a periodic orbit of \( f \). A cyclic permutation \( \theta \in C_n \) is called a **pattern** of \( Q \) if \( f(x_i) = x_{\theta(i)} \) for any \( i \in \mathbb{Z}_n \). Let

\[
F_\theta(I) \equiv F(I, \theta) = \{f \in C^0(I) : f \text{ has a periodic orbit of pattern } \theta\}.
\]

For any \( \gamma \) and \( \theta \in C \) with \( \gamma \neq \theta \), one says that \( \gamma \) **forces** \( \theta \) if \( F_\gamma(I) \subset F_\theta(I) \); denote it by \( \gamma \rightarrow \theta \) or \( \theta \leftarrow \gamma \). Then one obtains a transitive relation \( \rightarrow \) on \( C \). The relation \( \rightarrow \) is a refinement of the Sharkovskii ordering \( < \), which has been studied by many authors (see [1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 12, 23, 24], etc.). In the following we will also study this relation. By means of reductions of maps, we can obtain some new results.

For any \( \theta \in C \) and any \( \Theta \subset C \), let

\[
E(\theta) = \{\gamma : \gamma \in C \text{ and } \gamma \rightarrow \theta\}, \quad E(\Theta) = \{\gamma \in C : \gamma \rightarrow \theta \text{ for all } \theta \in \Theta\}
\]

and

\[
F_\theta^*(I) \equiv F^*(I, \theta) = F_\theta(I) - \bigcup_{\gamma \in C} F_\gamma(I) \text{ such that } F_\gamma^*(L(Q)) = F_\theta(L(Q)) - \bigcup_{\gamma \in E(\theta)} F_\gamma(L(Q)) : \gamma \in E(\theta)\}.\]

With a few changes in the proofs of Theorems 3.4 and 3.5 (for example, changing “periodic orbit with period \( n \)” to “periodic orbit of pattern \( \theta \)”, etc.), one has the following two theorems.

**Theorem 3.6.** For any \( f \in F_\theta(I) \), there exist a periodic orbit \( Q \) of \( f \) with pattern \( \theta \) and a normal reduction \( \varphi \) of \( f \) preserving \( Q \) such that

\[
\varphi \in F_\theta^*(L(Q)) = F_\theta(L(Q)) - \bigcup_{\gamma \in E(\theta)} F_\gamma(L(Q)) : \gamma \in E(\theta)\}.
\]

**Theorem 3.7.** For any \( \Theta \subset C \) with \( \Theta \neq \emptyset \),

\[
\bigcap_{\theta \in \Theta} F_\theta(I) - \bigcup_{\gamma \in E(\Theta)} F_\gamma(I) \neq \emptyset.
\]

As a corollary of Theorem 3.5 one has the following proposition, which is due to Baldwin [2].
Proposition 3.8. Let \( \theta, \gamma \in C \) with \( \theta \neq \gamma \). If \( \gamma \rightarrow \theta \), then \( \theta \neq \gamma \).

Definition 3.9. Let \( \gamma \in C_n, n \geq 1 \), and \( \eta \in C_{2n} \). \( \eta \) is called a doubling of \( \gamma \) if \( \eta(\{2i-1, 2i\}) = \{\gamma(i)-1, 2\gamma(i)\} \) for all \( i \in \mathbb{Z}_n \).

Example 3.10. See Figure 3: \( \eta \in C_4 \) is a doubling of \( \gamma \in C_2 \), but \( \xi \in C_4 \) is not.

![Figure 3](image-url)

The following result is due to Bernhardt [3], and a generalization (Theorem 6.3) will be given in Section 6.

Proposition 3.11. Let \( \gamma, \theta \in C \), and let \( \eta \) be a doubling of \( \gamma \). Then \( \eta \rightarrow \gamma \).

Moreover, if \( \eta \rightarrow \theta \) and \( \gamma \neq \theta \), then \( \gamma \rightarrow \theta \).

Theorem 3.12. Let \( \Theta \subset C \), and \( \Gamma = \{\gamma_1, \gamma_2, \ldots \} \subset E(\Theta) \). If for any \( n \in \mathbb{N} \) there exists an integer \( q(n) > n \) such that \( \gamma_n \rightarrow \gamma_{q(n)} \), then each \( f \in F_{\gamma_1}(I) \) has a reduction \( \varphi \in \cap \{F_{\gamma_0}(I) : \theta \in \Theta \} - \bigcup \{F_{\gamma_n}(I) : n \in \mathbb{N} \} \).

Proof. Note that \( f \in F_{\gamma_1}(I) \subset F_{\gamma_{q(1)}}(I) \). By Theorem 3.6 \( f \) has a periodic orbit \( Q_1 \) of pattern \( \gamma_{q(1)} \) and a normal reduction \( f_1 \) preserving \( Q_1 \) such that \( f_1 \in F_{\gamma_{q(1)}}(L(Q_1)) \). Write \( \beta_1 = \gamma_{q(1)} \). For \( n \geq 2 \), assume \( Q_{n-1}, \beta_{n-1} \) and \( f_{n-1} \) have been defined satisfying \( f_{n-1} \in F_{\beta_{n-1}}(L(Q_{n-1})) \). If \( f_{n-1} \notin F_{\gamma_n}(L(Q_{n-1})) \), then let \( Q_n = Q_{n-1}, \beta_n = \beta_{n-1} \) and \( f_n = f_{n-1} \). If \( f_{n-1} \in F_{\gamma_n}(L(Q_{n-1})) \), then let \( \beta_n = \gamma_{q(n)} \). Since \( F_{\gamma_n}(L(Q_{n-1})) \subset F_{\beta_n}(L(Q_{n-1})) \), one can take a periodic orbit \( Q_n \) of \( f_{n-1} \) with pattern \( \beta_n \) and a normal reduction \( f_n \) of \( f_{n-1} \) preserving \( Q_n \) such that \( f_n \in F_{\beta_n}(L(Q_n)) \). Write \( J_n = L(Q_n) \) for \( n \geq 1 \). By induction, one obtains infinite sequences \( \{f_n\}_{n=1}, \{Q_n\}_{n=1}, \{J_n\}_{n=1} \) and \( \{\beta_n\}_{n=1} \) which satisfy \( J_n = L(Q_n) \supset J_{n+1} \supset \beta_n \in \{\gamma_{q(i)} : i = 1, 2, \ldots, n\} \) and \( f_n \in F_{\beta_n}(J_n) - F_{\gamma_n}(J_n) \) is a reduction of \( f_{n-1} \) for all \( n \geq 1 \). Let \( J = \bigcap_{n=1}^{\infty} J_n \). By Proposition 2.4, \( f_{1}s, f_{2}s, f_{3}s, \ldots \) converges uniformly to a map \( g \in C^0(J) \), which is a reduction of \( f \) and of each \( f_n \). By Lemma 2.2 \( g \notin \bigcup \{F_{\gamma_n}(J) : n \in \mathbb{N} \} \).

For any \( \theta \in \Theta \) and \( n \in \mathbb{N} \), since \( \beta_n \in \Gamma \subset E(\Theta) \subset E(\theta) \), one has \( f_n \in F_{\beta_n}(J_n) \subset F_{\theta}(J_n) \). Let \( V_n = \{x \in P(f_n) : \text{the pattern of } O(x, f_n) \text{ is } \theta \} \) and \( v_n = \inf V_n \).

Then \( v_n \in P(f_n) \). Since the pattern of \( Q_n \) under \( f_i \) (\( 1 \leq i \leq n \)) is \( \beta_n \) and \( \beta_n \neq \theta \), one has \( V_1 \cap Q_n = \emptyset \). Note that \( f_n \) is piecewise monotonic. It follows from Lemma 3.2 that \( v_n \in V_n \). By Lemma 2.2 one has \( V_1 \supset V_2 \supset V_3 \supset \ldots \). Hence \( v_1 \leq v_2 \leq v_3 \leq \ldots \). Let \( w = \lim_{n \to \infty} v_n \). Then \( w \in P(g) \).

Suppose the period of \( \theta \) (and of \( O(v_n, f_n) \)) is \( k \). For \( i \in \mathbb{N} \), let \( v_n^i = f_n^i(v_n) \), and let \( (c_n^i, d_n^i) \) be the connected component of \( J_n - Q_n \) containing \( v_n^i \). Then \( (c_n^i, d_n^i) \subset Q_n \), and \( f_n | (c_n^i, d_n^i) \) is monotonic.

Suppose the pattern of \( O(w, g) \) is \( \zeta \). If \( \zeta \neq \theta \), then, by Lemma 3.2 \( \theta \) must be a doubling of \( \zeta \) and there exists a closed interval \( U_{\epsilon} = [w - \epsilon, w + \epsilon] \subset (c_1^k, d_1^k) \)
such that for any \( n \geq 1 \) and any \( x \in U_\varepsilon \cap P(f_m) \), the pattern of \( O(x, f) \) is \( \theta \) and \( f_m^n(U_\varepsilon) \subset [c_m^j, d_m^j] \) for all \( i \in \mathbb{Z}_k \). Take \( m \in \mathbb{N} \) such that \( v_m \in [w - \varepsilon, w) \) and \( v_m < v_{m+1} < w \). Then \( v_m \in P_\varepsilon(f_m) - P(f_{m+1}) \) and there is \( j \in \mathbb{Z}_k \) such that \( f_{m+1}(v_m^j) \neq f_m(v_m^j) \). Let \( [y_1, y_2] \) be the connected component of \( f_{m+1}^{-1}(f_{m+1}(v_m^j)) \cap [c_m^j, d_m^j] \) containing \( v_m^j \). Since \( f_{m+1} \) is a reduction of \( f_m \), by Definition 2.1 one has \( c_m^j \leq y_1 < v_m^j < y_2 \leq d_m^j \) and

\[
f_m(y_1) = f_{m+1}(y_1) = f_{m+1}(y_2) = f_m(y_2) = f_{m+1}(v_m^j) \neq f_m(v_m^j).
\]

This implies that \( f_m|_{[c_m^j,d_m^j]} \) is not monotonic, which yields a contradiction. Thus \( \zeta = \theta \) and \( g \in F_\varepsilon(J) \).

To sum up, we have proved that \( g \in \bigcap\{F_\theta(J) : \theta \in \Theta\} - \bigcup\{F_{\gamma_n}(J) : n \in \mathbb{N}\} \).

Suppose \( J = [c, d] \). Define \( \varphi \in C^0(I) \) by

\[
\varphi(x) = g(\max\{c, \min\{x, d\}\}), \quad \text{for any } x \in I.
\]

Then \( \varphi \) is also a reduction of \( f \) and \( \varphi \in \bigcap\{F_\theta(I) : \theta \in \Theta\} - \bigcup\{F_{\gamma_n}(I) : n \in \mathbb{N}\} \). \( \Box \)

### 3.3. The converse of Sharkovskii’s Theorem

To conclude this section, we go back to the converse of Sharkovskii’s Theorem. Let \( F(I, 2^\infty) \) and \( \Phi(I, 2^\infty) \) be as in Theorem 1.2. By an argument analogous to the proof of Theorem 3.12 one has

**Theorem 3.13.** Every \( f \in \Phi(I, 2^\infty) \) has a reduction \( \varphi \in F(I, 2^\infty) - \Phi(I, 2^\infty) \).

According to Theorem 3.13 one can obtain a family of maps in \( F(I, 2^\infty) - \Phi(I, 2^\infty) \), which are distinct from those given by Delahaye [18].

### 4. Patterns of invariant sets of interval maps

In this section we introduce the definition of patterns of invariant sets of interval maps, and we give some general results on the conditions under which one pattern can force another one. In the sequel, we will use the results of this section to study some special patterns.

#### 4.1. Patterns of invariant sets of interval maps

First, we introduce some notions. Recall that a pair \((X, \psi)\) is called a **line system** if \( X \) is a nonempty bounded subset of \( \mathbb{R} \) with the usual metric, \( \psi \) is a continuous map from \( X \) to \( X \), and \( \psi \) can be extended to an interval map. Note that if \((X, \psi)\) is a line system, then there exists a unique continuous map \( \overline{\psi} : \overline{X} \to \overline{X} \), called the **closure extension** of \( \psi \), such that \( \overline{\psi}|_{X} = \psi \). A line system \((X, \psi)\) is said to be **compact** if \( X \) is compact. Denote by \( \Psi \) (resp. \( \Psi_c \)) the family of all line systems (resp. compact line systems).

For any nonempty subsets \( X \) and \( Y \) of \( \mathbb{R} \), an injection \( h : X \to Y \) is said to be **order-preserving** if \( h(x) < h(y) \) for all \( x, y \in X \) with \( x < y \). It is clear that if both \( X \) and \( Y \) are compact, then every order-preserving bijection from \( X \) to \( Y \) is a homeomorphism.

**Definition 4.1.** Let \((X, \psi)\) and \((Y, \xi)\) be two line systems. We say that \((X, \psi)\) and \((Y, \xi)\) have the same **pattern** (for convenience, sometimes we also say that \( \psi \) and \( \xi \) have the same pattern) if there exists an order-preserving bijection \( h : X \to Y \) such that \( h\psi = \xi h \), and such a bijection \( h \) is called an **order-preserving conjugacy** from \( \psi \) to \( \xi \).
If \((X, \psi)\) and \((Y, \xi)\) have the same pattern, then denote it by \((X, \psi) \approx (Y, \xi)\), or \(\psi \approx \xi\) when it is possible without ambiguity.

**Example 4.2.** Let \(X = [-1, 1], J = [-2, 2]\), and let \(\psi : X \to X\) and \(f : J \to J\) be strictly decreasing continuous maps satisfying

\[
\begin{align*}
\psi(x) &= -x & \text{if } x \in [-1, 0] \cup \{1/n : n \in \mathbb{N}\}; \\
\psi(x) &> -x & \text{if } x \in \left(\frac{1}{n+1}, \frac{1}{n}\right), n \in \mathbb{N}; \\
f(y) &= \begin{cases} 
-y & \text{if } y \in [-2, 1]; \\
\psi(y - 1) - 1 & \text{if } y \in [1, 2].
\end{cases}
\end{align*}
\]

Let \(Y = [-2, -1) \cup \{0\} \cup (1, 2]\) and \(\xi = f|_Y\). Then \((X, \psi)\) and \((Y, \xi)\) have the same pattern. Note that their closure extensions \((X, \overline{\psi})\) and \((Y, \overline{\xi})\) do not have the same pattern. Since \(X\) is compact but \(Y\) is not, there is no homeomorphism \(H : X \to Y\) such that \(H\overline{\psi} = \overline{\xi}H\), and hence \((X, \psi)\) and \((Y, \xi)\) are not topologically conjugate.

**Remark 4.3.** Because of this example and many other analogous examples, in Definition 4.1 we do not require \(X\) and \(Y\) to be compact nor do we require the order-preserving bijection \(h\) to be a homeomorphism.

The reason why we have to focus on \(\Psi\) but not only \(\Psi_c\) is the phenomenon that happened in Example 4.2 (and Example 4.7, etc.) but not just because \(\Psi\) is a bigger family than \(\Psi_c\).

Denote by \(\Psi^*\) the set of equivalence classes in \(\Psi\) under the equivalence relation \(\approx\), i.e., \(\Psi^* = \Psi/\approx\). Then \(\Psi^*\) can be regarded as the set of patterns of invariant sets of interval maps. For \((X, \psi) \in \Psi\), one uses \([(X, \psi)]\) to denote the equivalence class containing \((X, \psi)\). It is easy to see that one can regard \(C\) as a subset of \(\Psi^*\).

### 4.2. Forcing relation

Let \((X, \psi) \in \Psi\), \(I = [a, b]\) and \(f : I \to I\) be an interval map. \(f\) is said to have an invariant set \(S\) with the pattern of \((X, \psi)\) or \(f\) exhibits \((X, \psi)\) on \(S\) if there exists an \(f\)-invariant set \(S\) such that \(f|_S\) and \(\psi\) have the same pattern, i.e., \((S, f|_S) \approx (X, \psi)\).

**Definition 4.4.** Let \((X, \psi), (Y, \xi) \in \Psi\). We say \([(X, \psi)]\) forces \([(Y, \xi)]\) if each interval map exhibiting \((X, \psi)\) also exhibits \((Y, \xi)\). Denote it by \([(X, \psi)] \Rightarrow [(Y, \xi)]\), or \((X, \psi) \Rightarrow (Y, \xi)\) and \(\psi \Rightarrow \xi\) when there is no confusion.

So we obtain a transitive relation \(\Rightarrow\) on \(\Psi^*\). The relation \(\Rightarrow\) defined in Section 3 is a restriction of \(\Rightarrow\) to \(C\). Hence, conversely, the relation \(\Rightarrow\) is an extension of \(\Rightarrow\). Note that in Definition 4.4 we do not insist that \((X, \psi) \neq (Y, \xi)\); thus we have \((X, \psi) \Rightarrow (X, \psi)\) for all \((X, \psi) \in \Psi\).

**Example 4.5.** Let \(\psi : \mathbb{Z}_3 \to \mathbb{Z}_3\) and \(\xi_n : \mathbb{Z}_n \to \mathbb{Z}_n\) be defined by \(\psi(1) = \xi(3) = 1, \psi(2) = 3, \xi_n(n) = 1,\) and \(\xi_n(i) = i + 1\) for \(1 \leq i < n\). Then it is well known that \(\psi\) forces \(\xi_n\) for all \(n \geq 1\).

**Example 4.6.** Let \(X = \{0, 1/2, 1\}\) and \(\psi : X \to X\) be defined by \(\psi(0) = 1/2, \psi(1/2) = 1\) and \(\psi(1) = 0\). Let \(Y = [0, 1]\) and \(\xi : Y \to Y\) satisfy that \(\xi|_X = \psi\)
and \( \xi \) is linear on the interval \([0, 1/2], [1/2, 1]\) (see Figure 4). Then \([[X, \psi]] \neq [[Y, \xi]]\), but \([[X, \psi]] \Rightarrow [[Y, \xi]]\) and \([[Y, \xi]] \Rightarrow [[X, \psi]]\). Hence the forcing relation on \( \Psi^* \) is not a partial ordering.

![Figure 4](image-url)

**Example 4.7.** Let \( X = \{-3, -2, 0, 2, 3\}, Y = \{-3, 0, 3\} \cup \{b_n, -b_n : n \in \mathbb{N}\} \) and \( W = \{-3, 0, 3\} \cup \{c_n, -c_n : n \in \mathbb{N}\} \), where

\[
b_n = 2^{-n}, \quad c_n = 1 + 2^{-n}, \quad \text{for all } n \in \mathbb{N}.
\]

Define \( \psi \in C^0(X), \xi \in C^0(Y) \) and \( \eta \in C^0(W) \) by

\[
\psi(0) = \xi(0) = \eta(0), \\
\psi(2) = \psi(3) = \xi(b_1) = \xi(3) = \eta(c_1) = \eta(3) = 3, \\
\psi(-2) = \psi(-3) = \xi(-b_1) = \xi(-3) = \eta(-c_1) = \eta(-3) = -3 \quad \text{and} \\
\xi(b_{n+1}) = b_n, \quad \xi(-b_{n+1}) = -b_n, \quad \eta(c_{n+1}) = c_n, \quad \eta(-c_{n+1}) = -c_n
\]

for all \( n \in \mathbb{N} \). Let \( Y' = Y - \{0\}, W' = W - \{0\} \), and let \( \xi' = \xi|_{Y'}, \eta' = \eta|_{W'} \). Then \( \{(X, \psi), (Y, \xi), (W, \eta), (Y', \xi'), (W', \eta')\} \subset \Psi \). It is easy to see that

\[
(X, \psi) \Rightarrow (Y, \xi) \approx (W, \eta) \Rightarrow (Y', \xi') \approx (W', \eta') \Rightarrow (X, \psi).
\]

Since \([[X, \psi]]\), \([[Y, \xi]]\) and \([[Y', \xi']]\) are pairwise unequal, from (4.1) we see that the relation \( \Rightarrow \) is not a partial order on \( \Psi^* \). Note that \( X \) and \( Y \) are compact, and \( W, Y' \) and \( W' \) are not compact. Obviously, there exists an interval map \( f \) such that \((X, \psi)\) is a subsystem of \( f \) and hence \( f \) exhibits \((Y, \xi)\), but \( f \) has no compact invariant set with the pattern of \((Y, \xi)\). This example also explains why we have to consider the relation \( \approx \) in \( \Psi \) but not only in \( \Psi_e \).

4.3. **A useful criterion for the forcing relation.** In the rest of this section we will give some conditions of a pattern forcing another. Theorem 4.12 is the main result of this section, and Theorem 4.12 is a useful criterion. We begin with some notions and notation used in the sequel.

**Definition 4.8.** Let \((X, \psi) \in \Psi\) and \( I = L[X] = [\inf X, \sup X] \). A map \( g \in C^0(I) \) is called a **monotonic extension** (resp. the **linear extension**) of \( \psi \) if \( g|_X = \psi \) and \( g \) is monotonic (resp. linear) on every connected component of \( I - X \). A map \( g \in C^0(I) \) is called a **strictly monotonic extension** of \( \psi \) if \( g|_X = \psi \), and for any
connected component \( J = (v, y) \) of \( I - X \), when \( g(v) \neq g(y) \), then \( g|_J \) is strictly monotonic, and when \( g(v) = g(y) \), then \( g|_J \) is constant.

Note that any map \( g \in C^0(L(S)) \) is both monotonic and linear on every singleton in \( L(S) \). Thus, \( g \) is a monotonic (resp. strictly monotonic, resp. linear) extension of \( \psi \) if and only if \( g \) is a monotonic (resp. strictly monotonic, resp. linear) extension of the closure extension \( \overline{\psi} \). Note that, for each line system \((X, \psi)\), \( \psi \) has a unique linear extension.

**Remark 4.9.** Let \( X \) and \( Y \) be nonempty bounded subsets of \( \mathbb{R} \) with an order-preserving bijection \( h : X \to Y \), let \( K \) be a connected component of \( L[X] - X \) and \( L[X] = [a, b] \). It is easy to see that

1. If \( K = (r, s) \) is an open interval, then the corresponding open interval \((h(r), h(s))\) is also a connected component of \( L[Y] - Y \).
2. If \( K = [r, s] \) is a closed interval, then it is possible that \( \sup(h(X \cap [a, r])) = \inf(h(X \cap [s, b])) \). In this case, the connected component of \( L[Y] - Y \) corresponding to \( K \) is a one point set \( \{h(X \cap [a, r])\} \).
   Conversely, if \( K = \{r\} \) is a one point set and \( r \notin \{a, b\} \), then it is possible that \( \sup(h(X \cap [a, r])) < \inf(h(X \cap [r, b])) \). In this case, the connected component of \( L[Y] - Y \) corresponding to \( K \) is a closed interval \( \{\sup(h(X \cap [a, r])), \inf(h(X \cap [r, b]))\} \).
3. If \( K \) is a semi-open interval, say, \( K = (r, s] \), then it is possible that \( h(r) = \inf(h(X \cap [s, b])) \). In this case, there is no connected component of \( L[Y] - Y \) corresponding to \( K \).
4. If \( X \) is compact, then every connected component of \( L[X] - X \) is an open interval.

According to Remark 4.9 in the following we only consider the connected components of \( L[X] - X \) which are open intervals.

**Definition 4.10.** Let \( X \subset \mathbb{R} \) be a nonempty bounded set, and \( I = L(X) \). A connected component \( K \) of \( I - X \) is called an open complementary interval of \( X \) if \( K \) is an open interval.

Denote by \( K(X) \) the set of all open complementary intervals of \( X \). Write

\[
U(X) = \bigcup \{ J : J \in K(X) \}.
\]

Then \( K(X) \subset K(X) \), \( U(X) \subset I - X \), and \( U(X) = I - X \) if and only if \( X \) is compact. For any \( y \in X \cup U(X) \), let

\[
K(y, X) = \begin{cases} J & \text{if } y \in J \text{ and } J \in K(X) ; \\ y & \text{if } y \in X . \end{cases}
\]

Let \((X, \psi)\) be a line system. For any monotonic extension \( f \) of \( \psi \) and any orbit \( O(x, f) \) contained in \( X \cup U(X) \), write

\[
I(x, f, X) = (K(x, X), K(f(x), X), K(f^2(x), X), \ldots) ,
\]

\[
I_m(x, f, X) = (K(x, X), K(f(x), X), \ldots, K(f^m(x), X)) \ (m \geq 0).
\]

The infinite sequence \( I(x, f, X) \) is called the itinerary of \( x \) under \( f \) relative to \( X \). It is easy to see that, if \( I_m(x, f, X) = I_m(y, f, X) \) but \( f^{m+1}(x) \neq f^{m+1}(y) \), then \( K(f^i(y), X) = K(f^i(x), X) \subseteq U(X) \) for \( 0 \leq i \leq m \).

For any nonempty subsets \( X \) and \( Y \) of \( \mathbb{R} \), one writes \( X < Y \) if \( x < y \) for any \( x \in X \) and any \( y \in Y \).
Lemma 4.11. Let $X, U(X)$ and $f$ be as above. Suppose $O(x, f)$ and $O(y, f)$ are two orbits contained in $X \cup U(X)$. Then $x < y$ if one of the following three conditions holds:

(i) $K(x, X) < K(y, X)$.

(ii) There is an $m \geq 0$ such that $I_m(x, f, X) = I_m(y, f, X), K(f^{m+1}(x), X) < K(f^{m+1}(y), X)$ and the number $\{0 \leq i \leq m : f|_{K(f(x), X)} \text{ is decreasing}\}$ is even.

(iii) There is an $m \geq 0$ such that $I_m(x, f, X) = I_m(y, f, X), K(f^{m+1}(x), X) > K(f^{m+1}(y), X)$, and the number $\{0 \leq i \leq m : f|_{K(f(x), X)} \text{ is decreasing}\}$ is odd.

The proof of Lemma 4.11 is analogous to that of [17] Lemma II.1.2 and is omitted.

Let $(J_0, J_1, J_2, \ldots)$ be an infinite sequence of open complementary intervals of $X$ such that $J_n = (r_n, s_n)$ and $[\psi(r_n); \psi(s_n)] \supset J_{n+1}$ for all $n \geq 0$. $J_0$ is said to be expanding under $\psi$ relative to $(J_0, J_1, J_2, \ldots)$ if there exist $j$ and $k \in \mathbb{N}$ such that $\psi^j(r_0) \notin \partial J_j$ and $\psi^k(s_0) \notin \partial J_k$.

Recall that an orbit $O(x, g)$ of a map $g \in C^0(X)$ is said to be eventually periodic if it is a finite set. $O(x, g)$ is called an infinite orbit if it is an infinite set. For $m \in \mathbb{N}$, an infinite sequence $(K_0, K_1, K_2, \ldots)$ is said to be periodic and have period $m$ if

$$(K_m, K_{m+1}, K_{m+2}, \ldots) = (K_0, K_1, K_2, \ldots) \neq (K_i, K_{i+1}, K_{i+2}, \ldots)$$

for $1 \leq i < m$.

The following theorem is a useful criterion for the forcing relation.

Theorem 4.12. Let $(X, \psi), (Z, \xi)$ be line systems. Suppose that there exists a monotonic extension $f$ of $\psi$ satisfying the following conditions:

(C.1) $f$ has an invariant set $V \subset X \cup U(X)$ such that $f|_V$ and $\xi$ have the same pattern;

(C.2) $I(x, f, X) \neq I(y, f, X)$ for any $x, y \in V \cap U(X)$ with $x \neq y$;

(C.3) for any $x \in V \cap U(X)$, if $O(x, f)$ is an infinite orbit contained in $U(X)$ or is a periodic orbit in an even state, then the open complementary interval $K(x, X)$ is expanding under $\psi$ relative to $(K(x, X), K(f(x), X), K(f^2(x), X), \ldots)$;

(C.4) for any $J = (v, y) \in K(X)$, if $\psi(v) = \psi(y)$, then $V \cap J = \emptyset$.

Then $[(X, \psi)] \Rightarrow [(Z, \xi)]$.

Proof. Consider any $g \in C^0(I)$, where $I$ is a compact interval. Assume $g$ has an invariant set $Y$ with the pattern of $\psi$. Then there is an order-preserving bijection $h : X \to Y$ such that $gh = h\psi$. In order to prove $\psi \Rightarrow \xi$, it suffices to show that $g$ has an invariant set $V'$ with the pattern of $f|_V$. Suppose $K(X) = \{J_i = (r_i, s_i) : i \in Z\}$, where $Z'$ is a subset of $\mathbb{N}$. For every $i \in Z'$, let $r'_i = h(r_i), s'_i = h(s_i)$, and $J'_i = (r'_i, s'_i)$. Then $J'_i$ is an open complementary interval of $Y$, $K(Y) = \{J'_i : i \in Z\}$ and $U(Y) = \{J'_i : i \in Z'\}$. Since $g(Y) \subset Y$, we have $g(Y) \subset Y$. By Theorem 2.3 there exists a normal reduction $\varphi$ of $g$ preserving $Y$. Obviously, one has

$$\varphi(J'_i) \supset J'_k \text{ if and only if } f(J_i) \supset J_k, \quad i, k \in Z'.
$$

Let $U' = U(Y)$, and $U'' = \{x \in U' : \varphi(x) = g(x)\}$. Then, by Definition 2.1 and Lemma 2.2 $\varphi$ is constant on every connected component of $U' - U''$, $P(\varphi) \cap U' \subset U''$ and

$$\varphi(\partial J'_i \cup (J'_i \cap U'')) = \varphi(J'_i), \quad \text{for any } i \in Z'.
$$

We are going to show that there exists an order-preserving injection $H : V \to Y \cup U''$ such that $HF|_V = \varphi H (= gH)$. Define $\beta : X \cup K(X) \to Y \cup K(Y)$ by
\(\beta(x) = h(x)\) for any \(x \in X\) and \(\beta(J_i) = J'_i\) for any \(i \in Z'\). Then \(\beta\) is an order-preserving bijection. For any sequence \((K_0, K_1, \ldots, )\) of elements in \(X \cup K(x)\) and any \(n \in \mathbb{N}\), let

\[
\beta((K_0, K_1, \ldots, K_n)) = (\beta(K_0), \beta(K_1), \ldots, \beta(K_n)),
\]

\[
\beta((K_0, K_1, K_2, \ldots, )) = (\beta(K_0), \beta(K_1), \beta(K_2), \ldots, ).
\]

Let \(V_0 = V \cap X\). For any \(v \in V_0\), define \(H(v) = h(v)\). Then

\[I(H(v), \varphi, Y) = \beta(I(v, f, X)).\]  

Let \(V_1 = P(f|V) \cap U(X)\). Take a subset \(V_2 \subset V_1\) such that, for every periodic orbit \(Q\) of \(f\) contained in \(U(X), V_2 \cap Q\) contains exactly one point. For any \(v \in V_2\), we claim that there is a point \(v' \in U'' \cap P(\varphi)\) and then we define \(H(v) = v'\) such that \((4.4)\) holds. In fact, suppose the period of \(v\) under \(f\) is \(m\) and \(I(v, f, X) = (J_{i(0)}, J_{i(1)}, J_{i(2)}, \ldots)\). Then, by the condition (C.2), the period of \((J_{i(0)}, J_{i(1)}, J_{i(2)}, \ldots)\) is also \(m\). If \(O(v, f)\) is in an odd state, then it follows from (4.2) that there exists a point \(y \in V\) such that \(q < t\) such that \(\varphi^n(q) = r'_{i(0)}\), \(\varphi^n(t) = s'_{i(0)}\), and \(\varphi^n((q, t)) \subset J_{i(m)}\) for all \(n \in \mathbb{Z}_m\). Thus there is also a point \(v' = H(v) \in (q, t) \cap P_2(\varphi)\) satisfying (4.3). For any \(v \in V_1 - V_2\), take \(u \in V_2\) and \(k \geq 1\) such that \(v = f^k(u)\), and put \(H(v) = \varphi^k(H(u))\). Obviously, for such a \(v\) and \(H(v)\), (4.3) still holds.

Let \(V_3 = \{x \in V : O(x, f) \subset U(X) - P(f)\}\). Take \(V_4 \subset V_3\) such that \(\bigcup_{n=0}^{\infty} \bigcup_{n=0}^{\infty} f^{-n}(f^n(V_4)) \supset V_3\) and \(O(x, f) \cap O(y, f) = \emptyset\) for any \(x, y \in V_4\) with \(x \neq y\). For any \(v \in V_4\) and any \(n \in \mathbb{N}\), it follows from (4.2) and (4.3) that there exists \(v'_n \in U''\) such that \(\varphi^n(v'_n) \in U''\) and \(I_n(v'_n, \varphi, Y) = \beta(I_n(v, f, X))\). Then by condition (C.3) it is easy to check that \(O(v'_n, \varphi) \subset U''\), and hence (4.3) holds for \(v \in V_4\).

Finally, for \(n = 1, 2, 3, \ldots\) and for every \(w \in f^{-n}(V_0 \cup V_1 \cup V_2) \cap V - f^{-n+1}(V_0 \cup V_1 \cup V_2)\), if \(H(f(w))\) has been defined, then by (4.2) and (4.3) and condition (C.4) one can continue to choose a point \(w' = H(w) \in U''\) such that

\[\varphi(H(w)) = H(f(w))\quad \text{and} \quad I(H(w), \varphi, Y) = \beta(I(w, f, X)).\]

Therefore, noting \(V = \bigcup_{n=0}^{\infty} f^{-n}(V_0 \cup V_1 \cup V_2) \cap V\), one obtains a map \(H : V \to U'' \cup Y\) which satisfies \(H|_V = \varphi H, H(P_m(f|V)) \subset P_m(\varphi)\) for any \(m \in \mathbb{N}\), and

\[I(H(x), \varphi, Y) = \beta(I(x, f, X))\]

for any \(x \in V\).

By (4.5), condition (C.2) and Lemma 4.11, \(H\) is an order-preserving injection. Let \(V' = H(V)\). Then \(g|_{V'} = \varphi|_{V'}\) and \(f|_{V'}\) have the same pattern. So the proof of Theorem 4.12 is completed.

### 4.4 Main results of this section

**Definition 4.13.** Let \((V, \xi)\) be a line system, and \(x, y \in V\) with \(x \neq y\). The orbits \(O(x, \xi)\) and \(O(y, \xi)\) are said to be **companionate orbits of \(\xi\)** if

(i) \(\xi|_{(x, \xi(x))} = \xi|_{(y, \xi(y))}\) is monotonic for all \(k \geq 0\);
(ii) for \( j > k \geq 0 \), if \([\xi^j(x); \xi^j(y)] \cap [\xi^k(x); \xi^k(y)]\) contains more than one point, then \([\xi^j(x); \xi^j(y)] = [\xi^k(x); \xi^k(y)]\).

Two companionate orbits \( O(x, \xi) \) and \( O(y, \xi) \) are said to be **self-companionate** if \( O(y, \xi) \subset O(x, \xi) \) or \( O(x, \xi) \subset O(y, \xi) \).

It is easy to check that if \( O(x, \xi) \) and \( O(y, \xi) \) are companionate infinite orbits, then they have the same pattern. If \( O(x, \xi) \) and \( O(y, \xi) \) are self-companionate periodic orbits of period \( n \), then \( n \) is even, \( y = \xi^{n/2}(x) \) and \([\xi^j(x); \xi^j(y)] \cap [\xi^j(x); \xi^j(y)] = \emptyset \) for \( 0 < i < j < n/2 \).

**Theorem 4.14.** Let \( (X, \psi) \) and \( (Z, \xi) \) be line systems, and let \( X \) be compact. Suppose \( \xi \) has no companionate orbits. Then \([X, \psi] \Rightarrow [Z, \xi] \) if and only if there exists a monotonic extension of \((X, \psi) \) which exhibits \( \xi \).

**Proof.** The necessity is clear. We now prove the sufficiency. Let \( U(X) \) and \( I = [\inf X, \sup X] \) be the same as in Definition 4.8. Since \( X \) is compact, we have \( I = X \cup U(X) \). Assume there is a monotonic extension \( f \) of \( \psi \) which has an invariant set \( W \) with the pattern of \( \xi \). In order to prove \( \psi \Rightarrow \xi \), it suffices to show that there exists an order-preserving injection \( H : W \to I \) such that \( fH = Hf|_W \) and the conditions (C.2)–(C.4) in Theorem 4.12 hold for \( V = H(W) \). Let

\[
W_0 = \{ v \in W : \mathcal{O}(v, f) \subset U(X) \},
V_1 = \{ v \in W_0 : \text{any } n \geq 0, K(f^n(v), X) \text{ is expanding under } \psi \text{ relative to } (K(f^n(v), X), K(f^{n+1}(v), X), K(f^{n+2}(v), X), \ldots) \},
V_2 = \{ v \in W_0 : \text{there exists a } j \geq 0 \text{ such that } \mathcal{O}(f^j(v), f) \text{ is a periodic orbit in an odd state} \},
V_3 = \{ v \in W_0 : \mathcal{O}(v, f) \text{ is an infinite orbit and } K(v, X) \text{ is not expanding under } \psi \text{ relative to } (K(v, X), K(f(v), X), K(f^2(v), X), \ldots) \},
V_4 = \{ v \in W_0 : \mathcal{O}(v, f) \text{ is a periodic orbit in an even state and } K(v, X) \text{ is not expanding under } \psi \text{ relative to } (K(v, X), K(f(v), X), K(f^2(v), X), \ldots) \},
V_5 = \bigcup_{i=0}^\infty f^{-i}(V_5) \cap W,
V_6 = \bigcup_{i=0}^\infty f^{-i}(V_6) \cap W,
V_7 = \bigcup_{i=0}^\infty f^{-i}(V_7) \cap W,
V_8 = \bigcup_{i=0}^\infty f^{-i}(V_8) \cap W,
V_9 = \bigcup_{i=0}^\infty f^{-i}(V_9) \cap W,
\]

and

\[
W_1 = \{ v \in W : \mathcal{O}(v, f) \cap X \neq \emptyset \},
V_7 = W_1 \cap X = W \cap X,
V_8 = f^{-1}(V_7) \cap W_1 - V_7 = f^{-1}(V_7) \cap W \cap U(X),
V_{81} = \{ v \in V_8 : f|_{K(v, X)} \text{ is not constant} \},
V_{82} = \{ v \in V_8 : f|_{K(v, X)} \text{ is constant} \},
V_{91} = \bigcup_{i=0}^\infty f^{-i}(V_{91}) \cap W_1,
V_{92} = \bigcup_{i=0}^\infty f^{-i}(V_{92}) \cap W_1.
\]

Then one has \( W_0 \cup W_1 = W, W_0 \cap W_1 = \emptyset, V_3 \subset V_5, V_4 \subset V_6, \bigcup_{i=1}^6 V_i = W_0, V_{81} \subset V_{91}, V_{82} \subset V_{92}, \text{ and } V_7 \cup V_{91} \cup V_{92} = W_1 \). Note that \( V_1 \cup V_2, V_5, V_6, V_7, V_{91} \) and \( V_{92} \) are pairwise disjoint, and \( V_1 \cup V_2, V_3, V_4, V_5, V_6, V_7 \cup V_{91}, V_7 \cup V_{92} \) and \( V_7 \cup V_{92} \) are all invariant under \( f \).

Take \( V_{30} \subset V_3 \) and \( V_{40} \subset V_4 \) such that \( \bigcup_{i=0}^\infty \bigcup_{j=0}^\infty f^{-i}(f^n(V_{j0})) \supset V_{j+2} \) (\( j = 3, 4 \)), and \( \mathcal{O}(x, f) \cap \mathcal{O}(y, f) = \emptyset \) for any \( \{ x, y \} \subset V_{30} \cup V_{40} \) with \( x \neq y \). Denote \( V_{31} = \bigcup_{x \in V_{30}} \mathcal{O}(v, f) = v \in V_{30} \}. \) Then \( \bigcup_{i=0}^\infty f^{-i}(V_{31} \cup V_4) \supset V_5 \cup V_6 \).

We now define a map \( H : W \to I \) as follows:

**Step 1.** For any \( v \in V_1 \cup V_2 \cup V_7 \cup V_{91}, \text{ let } H(v) = v.**
Step 2. For any $v \in V_{30} \cup V_{40}$, since $K(v, X)$ is not expanding under $\psi$ relative to $(K(v, X), K(f(v), X), \ldots)$, there exists $y_n \in \partial K(f^n(v), X)$ such that $\psi^n(y_n) \in \partial K(f^n(v), X)$ for all $n \geq 0$. Note that if $v \in V_{40}$ and if the period of $v$ is $k$, then $\psi^k(y_n) = f^k(y_n) = y_n$ since $O(v, f)$ is in an even state. Thus we can put $H(v) = y_n$, and put $H(f^n(v)) = \psi^n(y_n) (= f^n(H(v)))$ for all $n \geq 1$. Hence $H_{\mid (V_{31} \cup V_{41})}$ is defined.

Step 3. For $n = 1, 2, 3, \ldots$ and for every $v \in f^{-n}(V_{31} \cup V_4 \cup V_7) \cap W - f^{-n+1}(V_{31} \cup V_4 \cup V_7)$, if $H(f(v))$ has been defined and $H((f(v))) \in K(f(v), X)$, then we can take a point $v' \in K(v, X)$ such that $f(v') = H(f(v))$ (in particular, if $n = 1$ and $v \in V_{62}$, we take $v' \in \partial K(v, z)$; if $v \in V_{31}$, we take $v' = v$ and then we put $H(v) = v'$.

From these three steps we obtain a map $H : W \rightarrow I$ which satisfies

$$fH = Hf \mid W \text{ and } H(v) \in K(v, X) \text{ for all } v \in W.$$  

Now we prove that $H$ is an order-preserving injection. We divide the proof into several claims.

Claim 1. $fH \mid W$ has no companionate orbits.

Since $fH \mid W$ and $\xi$ have the same pattern, and $\xi$ has no companionate, we have Claim 1.

Claim 2. If $v \in V_{31}$, then $f^n([H(v); v]) = [Hf^n(v); f^n(v)]$ and $[Hf^n(v); f^n(v)] \cap [H(v); v] = \emptyset$ for each $n \in \mathbb{N}$.

Proof of Claim 2. Note that $O(v, f)$ is an infinite orbit in $U(X)$, $f$ is monotonic on every connected component of $U(X)$, and $Hf(v) = fH(v) \in X$ for all $i \geq 0$.

Thus $f^n([H(v); v]) = [Hf^n(v); f^n(v)]$ for $n \in \mathbb{N}$. Write $v_i = f^i(v)$. If Claim 2 is not true, then there is a minimal positive integer $n$ such that $[H(v_n); v_n] \cap [H(v); v] \neq \emptyset$. This implies that one of the following three cases holds:

Case 1. $H(v_n) = H(v)$ and $(H(v_n); v_n) \cap (H(v); v) \neq \emptyset$. In this case, for $i = 1, 2, 3, \ldots$, one has $H(v_{in}) = H(v)$, and

$$\left((H(v_{in}); v_{in}) \cap (H(v_{in-n}); v_{in-n}) \right)$$

It follows that $(H(v_{in}); v_{in}) \cap (H(v); v) \neq \emptyset$ and $(v, v_n, v_{2n}, v_{3n}, \ldots)$ is a strictly monotonic sequence of points in $\bigcup_{i=0}^{\infty}(H(v); v_{in}) \subset K(v, X)$. Obviously, for $0 \leq k < j < n$, $(v_k, v_{n+j}, v_{2n+j}, \ldots)$ is also a strictly monotonic sequence in $\bigcup_{i=0}^{\infty}(H(v_j); v_{in+k}) \cap (\bigcup_{i=0}^{\infty}(H(v_j); v_{in+k})) = \emptyset$. Hence $O(v, f)$ and $O(v_n, f)$ are companionate orbits. But this contradicts Claim 1.

Case 2. $H(v_n) \neq H(v)$ and $(H(v_n); v_n) \cap (H(v); v) \neq \emptyset$. In this case, letting $w$ be another endpoint of the open interval $K(v, X)$ except $H(v)$, we have $H(v_n) = w, v_n \in (H(v); v), \forall v_n (v); v_n \in (H(v); w)$ and $H(v_{2n}) = H(v)$. Similar to Case 1, it is easy to see that $(v_j, v_{n+j}, v_{2n+j}, v_{3n+j}, \ldots)$ is a strictly monotonic sequence in $\bigcup_{i=0}^{\infty}(H(v_{n+j}); v_{2n+j}) \subset K(v_{n+j}, X) = K(v, X)$ for $0 \leq j < \infty$ and

$$(\bigcup_{i=0}^{\infty}(H(v_{n+k}); v_{2n+k})) \cap (\bigcup_{i=0}^{\infty}(H(v_{n+k}); v_{2n+k})) = \emptyset \text{ for } \forall 0 \leq k < j < 2n.$$  

Hence $O(v, f)$ and $O(v_{2n}, f)$ are companionate orbits. But this also contradicts Claim 1.
Case 3. $H(v_n) = H(v)$ and $(H(v_n); v_n) \cap (H(v); v) = \emptyset$. In this case we have $H(v_{2n}) = H(v)$. If $(H(v_{2n}); v_{2n}) \cap (H(v); v) \neq \emptyset$, then similar to Case 2, it is easy to check that $O(v; f)$ and $O(v_{2n}; f)$ are companionate orbits. If $(H(v_{2n}); v_{2n}) \cap (H(v); v) = \emptyset$, then $(H(v_{2n}); v_{2n}) \cap (H(v_n); v_n) \neq \emptyset$, and similar to Case 1, it is easy to check that $O(v_n; f)$ and $O(v_{2n}; f)$ are companionate orbits. But both still contradict Claim 1. Therefore, we have Claim 2.

Claim 3. Let $v \in V$ with period $m$. Then $f^i([H(v); v]) = [H f^i(v); f^i(v)]$ for $i = 1, 2, 3, \ldots, f^m([H(v); v]) = [H(v); v]$ and $[H f^n(v); f^n(v)] \cap [H(v); v] = \emptyset$ for each $n \in \{1, \ldots, m-1\}$.

The proof of Claim 3 is analogous to that of Claim 2, and is omitted.

Claim 4. For any $v, y \in W$,

(4.7) $(v; H(v)] \cap W = \emptyset,$

and

(4.8) $H(y) \neq H(v), \text{ if } y \neq v.$

Proof of Claim 4. Let $Y_0 = V_1 \cup V_2 \cup V_7 \cup V_9$, $Y_1 = Y_0 \cup V_3 \cup V_4 \cup V_8$ and $Y_i = f^{-1}(Y_{i-1}) \cap W$ ($i = 2, 3, 4, \ldots$). Then

(4.9) $f(Y_{j+1}) \subset Y_j \subset Y_{j+1}$, for $j = 0, 1, 2, \ldots,$

and

(4.10) $\bigcup_{j=0}^{\infty} Y_j = W.$

If $\{v, y\} \subset Y_0$, then from Step 1 of the definition of $H$ one has that (4.7) and (4.8) hold.

If $v \in V_3 \cup V_4 \cup V_8$ and $y \in Y_1$, then, by Claims 1–3, it is easy to check that (4.7) and (4.8) hold.

We now assume that (4.7) and (4.8) hold for all $\{v, y\} \subset Y_n$, where $n \geq 1$. If (4.7) does not hold for some $v \in Y_{n+1}$, then there is a $w \in (v; H(v)] \cap W$. Since $f^i[v, H(v)]$ is monotonic, $f^i(w) \in [f(v); H f(v)] \cap W$. This with $(f(v); H f(v)] \cap W = \emptyset$ implies $f(w) = f(v)$, which leads to $f^i(w; v)] = \{f(v)\}$. If there exists a minimal integer $k \geq 0$ such that $f^k(f(v)) \in (w; v)$, we put $z = f^{k+1}(v)$. If $O(f(v), f) \cap (w; v) = \emptyset$, we put $z = w$. Then $O(z, f)$ and $O(v, f)$ will be companionate orbits contained in $W$. But this contradicts Claim 1. Thus (4.7) still holds for all $v \in Y_{n+1}$.

If (4.8) does not hold for some $v, y \in Y_{n+1}$, i.e. if there exist $y$ and $v$ in $Y_{n+1}$ with $y \neq v$ such that $H(y) = H(v)$, then $H f(y) = f H(y) = f H(v) = H f(v)$. Since $\{f(y), f(v)\} \subset Y_n$, by the assumption, $f(y) = f(v)$. Noting that it has been proved that $(v; H(v)] \cap W = \emptyset$ and $(y; H(v)] \cap W = \emptyset$, one has $(v; y) \cap W = \emptyset$. Thus $O(v, f)$ and $O(y, f)$ are companionate orbits. But this contradicts Claim 1. Hence (4.8) also holds for all $v, y \in Y_{n+1}$.

By induction, (4.7) and (4.8) hold for all $v, y \in W$. Claim 4 is proven.

Let $V = H(W)$. As a direct corollary of Claim 4, one has

Claim 5. $H : W \rightarrow I$ is an order-preserving injection. Thus $f|_V$ and $f|_W$ have the same pattern as $\xi$. 

By Claim 1, \( f|_V \) has no companionate orbits, and hence the condition (C.2) in Theorem 4.12 holds. From step 2 (resp. step 3, the case that \( n = 1 \) and \( v \in V_{g_2} \)) of the definition of \( H \) it is easy to see that the condition (C.3) (resp. (C.4)) in Theorem 4.12 holds. Hence, by Theorem 4.12 we have \( \psi \Rightarrow \xi \). The proof of the theorem is completed. □

**Theorem 4.15.** Let \( X = \{x_1 < x_2 < \cdots < x_n\} \) be a finite subset of \( \mathbb{R} \), \( n \geq 3 \), \( \psi : X \to X \) be a cyclic permutation, and \( \xi \) be the linear extension of \( \psi \). If \( n \) is odd, or \( n \) is even but \( O(x_1, \psi) \) and \( O(\psi^{n/2}(x_1), \psi) \) are not companionate orbits, then \( \psi \Rightarrow \xi \).

**Proof.** Take \( f = \xi \), and \( V = [X] (= [x_1, x_n]) \). Then the conditions (C.1) and (C.4) in Theorem 4.12 hold. From the hypotheses it is easy to check that there exists a constant number \( c > 1 \) such that for any \( i \in \{2, 3, \cdots, n\} \), \( k \geq 1 \), and any \( \{y, w\} \subseteq \{x_{i-1}, x_i\} \), if \( \{f^k(y), f^k(w)\} \subseteq \{x_{i-1}, x_i\} \), then \( |f^k(y) - f^k(w)| \geq c \cdot |y - w| \). This implies that the conditions (C.2) and (C.3) also hold. Hence, by Theorem 4.12 we obtain Theorem 4.15. □

### 5. Periodic and nonperiodic minimal patterns

In Section 4 we give some general results on conditions under which one pattern can force another. It is natural to ask whether one can weaken the condition when a pattern has some special form. In this section we study the periodic and nonperiodic minimal patterns.

#### 5.1. Periodic patterns

It is well known that for any \( \eta \) and \( \theta \in C \) with \( \eta \neq \theta \), \( \eta \) forces \( \theta \) if and only if the linear extension of \( \eta \) has a periodic orbit of pattern \( \theta \) (see [1, 2, 10, 23]). The following Theorem 5.2 is a generalization of this result. To prove Theorem 5.2 one needs the following lemma.

**Lemma 5.1.** Let \( I = [a, b] \), \( f \in C^0(I), \theta \in C_n \) \((n \geq 1)\) and \( S \supset \{a, b\} \) be a nonempty closed invariant set of \( f \). Suppose that \( f \) is monotonic on every connected component of \( I - S \) and \( f|_S \) has no periodic orbit of pattern \( \theta \). If \( f \) has a periodic orbit \( W = \{w_1 < w_2 < \cdots < w_n\} \) of pattern \( \theta \) in an even state, then \( f \) has a periodic orbit \( V = \{v_1 < v_2 < \cdots < v_n\} \) of pattern \( \theta \) in an odd state such that \( v_n > w_n \) and

\[
(5.1) \quad O(x, f) \not\subset [a, w_n), \text{ for any } x \in \bigcup_{i=1}^n [w_i; v_i],
\]

\[
(5.2) \quad [w_i; v_i] \cap [w_j; v_j] = \emptyset, \text{ for } 1 \leq i < j \leq n.
\]

**Proof.** Let \( w = w_n \) and

\[
(5.3) \quad X_0 = \{x \in [w, b] : f^n(x) \geq w\}.
\]

Then \( X_0 \) is closed. Take \( \varepsilon > 0 \) such that \( [w - 3\varepsilon, w + 3\varepsilon] \subseteq [w_{n-1}, b] \) and

\[
(5.4) \quad \bigcup_{i=1}^{n-1} f^i([w - \varepsilon, w + \varepsilon]) \subset [a, w - \varepsilon] - S.
\]

Then \( f^n|_{[w, w+\varepsilon]} \) is increasing since \( O(w, f) \) is in an even state. Thus \( f^n([w, w+\varepsilon]) \subset [w, b] \), and hence \( [w, w + \varepsilon] \subseteq X_0 \).
Let $X$ be the connected component of $X_0$ containing $[w, w + \varepsilon]$. Then there is $z \in [w + \varepsilon, b]$ such that $X = [w, z]$. Obviously, one has $z = b \in S$ or $f^n(z) = w$. We claim that the following two equations hold:

$$
(5.5) \quad \bigcup_{i=1}^{n-1} f^i(X) \subset [a, w - \varepsilon],
$$

$$
(5.6) \quad f^i(X) \cap f^j(X) = \emptyset, \quad \text{for all } 0 \leq i < j < n.
$$

In fact, if (5.5) does not hold, then there will be $x \in X$ and $j \in Z_{n-1}$ such that $f^j(x) = w - \varepsilon$. This implies $f^n(x) = f^{n-j}(w - \varepsilon) \in [a, w - \varepsilon]$, which is a contradiction to (5.3). Similarly, if (5.6) does not hold, then there will be $x, y \in X$ and $i, j \in \{0, 1, \ldots, n - 1\}$ with $i < j$ such that $f^i(x) = f^j(y)$. This implies $f^n(y) = f^{n-j}(f^i(x)) = f^n(x) \in [a, w - \varepsilon]$, which is also a contradiction to (5.3). Thus (5.5) and (5.6) must hold.

Let $Y = X \cap P_n(f)$. Then $Y$ is closed and $w \in Y$. Let $v = \max Y$ and $O(v, f) = V = \{v_1 < v_2 < \ldots < v_n\}$. It follows from (5.5) that $v = v_n$ and

$$
(5.7) \quad f^n(x) \neq x \quad \text{for all } x \in (v, z].
$$

By (5.6) one has (5.2). Hence $V$ and $W$ have the same pattern as $\theta$. Since $f|_S$ has no periodic orbit of pattern $\theta$, $V \cap S = \emptyset$.

We now prove that $V$ is in an odd state. In fact, if $V$ is in an even state, putting

$$
T = \{x \in [v, z] : f^n(x) \in S\},
$$

then $T$ is closed and $T \subset (v, z) \subset X$. If $T = \emptyset$, then $z < b$ and there exists $\delta \in (0, b - z]$ such that $f^n([v, z + \delta]) \cap S = \emptyset$, which implies $\bigcup_{i=0}^{n-1} f^i([v, z + \delta]) \cap S = \emptyset$. From this it follows that $f^n([v, z + \delta])$ is increasing, $f^n([v, b]) \subset [v, b]$ and hence $[w, z + \delta] \subset X$. But this contradicts with $X = [w, z]$. If $T \neq \emptyset$, writing $t = \min T$ and $b_1 = \min(S \cap [v, b])$, then $b_1 > t > v$. Since $f^n([v, t]) \cap S = \emptyset$, one has $\bigcup_{i=0}^{n-1} f^i([v, t]) \cap S = \emptyset$. Thus $f^n([v, t])$ is increasing and $f^n(t) = b_1$. Noting that $f|_S$ has no periodic orbit of pattern $\theta$, by (5.6) one has $b_1 > t$. This with (5.7) yields $f^n(z) > z$, which still contradicts that $z = b$ or $f^n(z) = w$.

Therefore, $V$ must be in an odd state and hence $v > w$. Since

$$
\bigcup_{i=1}^{n} [w_i; v_i] \subset \bigcup_{j=0}^{n-1} f^j([w, v]) \subset \bigcup_{j=0}^{n-1} f^j(X) \subset \bigcup_{j=0}^{n-1} f^j(X_0),
$$

by (5.6) one can obtain (5.1). \hfill \square

**Theorem 5.2.** Let $(X, \psi)$ be a compact line system, and $\theta \in C$ be a pattern of a periodic orbit. Then $\psi \Rightarrow \theta$ if and only if there exists a monotonic extension of $\psi$ which has a periodic orbit of pattern $\theta$.

**Proof.** It is enough to show the sufficiency. If $\psi$ itself has a periodic orbit of pattern $\theta$, then one has $\psi \Rightarrow \theta$ immediately. Now assume that $\psi$ has no periodic orbit of pattern $\theta$, but there is a monotonic extension $f$ of $\psi$ which has a periodic orbit $W$ of pattern $\theta$. Then, by Lemma 5.1, $f$ has a periodic orbit $V$ of pattern $\theta$ in an odd state. Evidently, $f$ with $V$ satisfies the conditions (C.1)–(C.4) in Theorem 4.12. Thus one has $\psi \Rightarrow \theta$. \hfill \square
5.2. Nonperiodic minimal patterns. Now we study the nonperiodic minimal patterns. Note that even if \((X, \psi) \in \Psi\) is minimal, not every element in \([[(X, \psi)]\) is minimal. Generally we do not have a similar theorem such as Theorem 5.2 for a minimal pattern. But if we borrow the definition by Bobok [13], we can say more. First let us recall some definitions.

Let \((X, \psi) \in \Psi\). We say that a system \((X, \psi)\) is minimal if it is compact and every point in \(X\) has a dense orbit. It is easy to see that a compact system \((X, \psi)\) is minimal if and only if it has no proper nonempty closed invariant subset. A point \(x\) is said to be minimal if its orbit closure is a minimal system. It is well known that a point \(x\) is minimal if and only if its recurrent time is syndetic; i.e. for any neighborhood \(U\) of \(x\), the set \(N(x, U) = \{n \in \mathbb{N} : f^n(x) \in U\}\) has a bounded gap (see, for example, [21]). Obviously, each periodic orbit is minimal, and it is easy to verify that if \(x\) is minimal under \(f\), then it is also minimal under \(f^n\) for any \(n \in \mathbb{N}\).

Denote \(\mathcal{M} = \{(X, \psi) \in \Psi : (X, \psi)\) is minimal\}. For \((X, \psi), (Y, \xi) \in \mathcal{M}\), one says that \((X, \psi)\) is B-equivalent to \((Y, \xi)\), denoted by \((X, \psi) \approx_B (Y, \xi)\), if the map \(h: O(\min X, \psi) \to O(\min Y, \xi)\) defined by \(h(\psi^n(\min X)) = \xi^n(\min Y)\) for all \(n \geq 0\) is an order-preserving bijection. For \((X, \psi) \in \mathcal{M}\), write 
\[
[(X, \psi)]_B = \{(Y, \xi) \in \mathcal{M} : (X, \psi) \approx_B (Y, \psi)\}.
\]

**Lemma 5.3.** Let \((X, f)\) and \((Y, g)\) be compact line systems. Suppose that \((X, f)\) is minimal but not periodic, and \(x = \min X\). If there exists \(y \in Y\) such that the map \(h : O(x, f) \to O(y, g)\) defined by \(h(f^n(x)) = g^n(y)\) for all \(n \in \mathbb{Z}_+\) is an order-preserving bijection, then there exists a minimal set \(Y'\) of \(g\) such that \((X, f) \approx_B (Y', g)\).

**Proof.** Let \(y = h(x)\). Since \((X, f)\) is minimal but not periodic, there is some strictly decreasing sequence \(\{f^n(x)\}_{n=1}^{\infty}\) such that \(x = \lim_{n \to \infty} f^n(x)\). For each \(n \in \mathbb{N}\), denote \(f^n(x)\) and \(g^n(y)\) by \(x_n\) and \(y_n\), respectively. Since \(h\) is order-preserving, \(\{y_n\}_{n=1}^{\infty}\) is also strictly decreasing and hence converges to some point \(y' \in Y\). Let \(Y' = \overline{O(y', g)}\). Define \(h': O(x, f) \to O(y', g)\) by \(h'(f^n(x)) = g^n(y')\) for any \(n \in \mathbb{N}\).

First, we show that \(O(y', g)\) is infinite. Let \(k, j, n \in \mathbb{N}\) such that \(f^k(x) < f^j(x) < f^j(x)\). By continuity of \(f^n\), there exists an \(i_0 \in \mathbb{N}\) such that \(f^k(x_n) < f^i(x_n) < f^j(x_n)\) for all \(i \geq i_0\), where \(x_n = f^n(x)\) as defined in the previous paragraph. Since \(h\) is order-preserving on \(O(x, f)\), \(g^i(y) < g^i(y_n) < y^i(y)\) for any \(i \geq i_0\). Letting \(i\) tend to \(\infty\), one has \(g^i(y') \in [g^i(y), g^i(y')]\). From this it is easy to see that \(O(y', g)\) is infinite.

Consider any \(j, k \in \mathbb{N}\). If \(f^j(x) < f^k(x)\), then, since \(f\) is continuous, there exists an \(i_0 \in \mathbb{N}\) such that \(f^k(x) < f^i(x_n)\) for any \(i \geq i_0\). But \(h\) is order-preserving on \(O(x, f)\); hence \(g^i(y_n) < g^i(y_n)\) for any \(i \geq i_0\). Taking the limit, one has \(g^i(y') \leq g^i(y')\). Since \(O(y', g)\) is infinite, one gets \(g^i(y') < g^i(y')\), i.e. \(h'(f^k(x)) < h'(f^i(x))\). This means that \(h'\) is order-preserving, and it follows from \(x = \min O(x, f)\) that \(y' = \min O(y', g)\). Thus \(y' = \min Y'\).

Now we show that \(y'\) is a minimal point. It is well known that a point is minimal if and only if the sequence of the times at which this point returns to any given neighborhood is syndetic, i.e. has a bounded gap. So it suffices to show that for any \(\varepsilon > 0\), the set \(N(y', [y', y' + \varepsilon]) = \{k \in \mathbb{N} : g^k(y') \in [y', y' + \varepsilon]\}\) is syndetic. Since \(y' = \lim_{n \to \infty} y_n\), there is some \(j \in \mathbb{N}\) such that \(y_n = g^j(y) \in [y', y' + \varepsilon]\). Now consider \([x, x_n]\). For any \(k \in N(x, [x, x_n])\), one has \(f^k(x) \in [x, x_n]\).
Similar to the analysis above, one can show \( g^k(y') \in [y', y' + \varepsilon] \). That means \( N(x, [x, x_{n_j}]) \subset N(y', [y', y' + \varepsilon]) \). As \( x \) is minimal, \( N(x, [x, x_{n_j}]) \) and hence \( N(y', [y', y' + \varepsilon]) \) is syndetic. So \( y' \) is minimal and \( (Y', g_{|Y'}) \) is a minimal system. \( \square \)

**Definition 5.4.** Let \((W, \varphi)\) and \((X, \psi)\) be line systems. Suppose that \((X, \psi)\) is minimal but not periodic. We say that \((W, \varphi)\) forces \([X, \psi])_B \) and write \([W, \varphi)] \rightarrow [X, \psi])_B \) if any interval map exhibiting \((W, \varphi)\) has a minimal set which is \( B \)-equivalent to \((X, \psi)\).

**Theorem 5.5.** Let \((W, \varphi)\) and \((X, \psi)\) be line systems. Suppose that \((X, \psi)\) is minimal but not periodic, \( x = \min X, X' = \mathcal{O}(x, \psi), \) and \( \psi' = \psi|_{X'} : X' \to X' \). If \([W, \varphi)] \rightarrow [(X', \psi')], \) then \([W, \varphi)] \rightarrow [(X, \psi)]_B \).

**Proof.** Let \( g \) be an interval map which exhibits \((W, \varphi)\). Then \( g \) exhibits \((X', \psi')\) since \([W, \varphi)] \rightarrow [(X', \psi')]. \) Thus there exist an invariant set \( Y_0 \) of \( g \) and an order-preserving bijection \( h : X' \to Y_0 \) such that \( bhg = gh \). Let \( y = h(x) \) and \( Y_0 = \mathcal{O}(y, g) \). By Lemma 5.3 there exists a minimal set \( y' \) of \( g \) such that \((X, f) \approx_B (Y', g|_{Y'}). \) This means that \([W, \varphi)] \rightarrow [(X, \psi)]_B \). \( \square \)

For any \((X, \psi) \in \Psi \) and any \( x \in X \), one has \([X, \psi])] \rightarrow [\mathcal{O}(x, \psi), \psi|_{\mathcal{O}(x, \psi)}]). \)

Hence, by Theorem 5.5 we obtain

**Corollary 5.6.** Let \((W, \varphi)\) and \((X, \psi)\) be line systems. Suppose that \((X, \psi)\) is minimal but not periodic. If \([W, \varphi)] \rightarrow [(X, \psi)], \) then \([W, \varphi)] \rightarrow [(X, \psi)]_B \).

**Lemma 5.7.** Let \((X, \psi)\) be a minimal line system but not periodic, and \( x \in X. \) Then \( \mathcal{O}(x, \psi), \psi|_{\mathcal{O}(x, \psi)} \) has no companionate orbits.

**Proof.** Write \( x_n = \psi^n(x) \) for all \( n \in \mathbb{Z}_+. \) If there exist \( n \in \mathbb{Z}_+ \) and \( k \in \mathbb{N} \) such that \( \mathcal{O}(x_n, \psi) \) and \( \mathcal{O}(x_{n+k}, \psi) \) are a pair of companionate orbits, then, by (ii) of Definition 4.13 \((x_n, x_{n+k}, x_{n+2k}, x_{n+3k}, \ldots) \) is a strictly monotonic sequence, and \( x_n \) is a minimal point of neither \( \psi^k \) nor \( \psi. \) But this will lead to a contradiction. Thus the proof is completed. \( \square \)

**Theorem 5.8.** Let \((W, \varphi)\) be a compact line system, and \((X, \psi)\) be a minimal line system but not periodic. If there exists a monotonic extension \( f \) of \((W, \varphi)\) exhibiting \((X, \psi), \) then \([W, \varphi)] \rightarrow [(X, \psi)]_B \).

**Proof.** Let \( x = \min X, X' = \mathcal{O}(x, \psi) \), and \( \psi' = \psi|_{X'} : X' \to X'. \) Then \( f \) also exhibits \((X', \psi'). \) By Lemma 5.7 \((X', \psi') \) has no companionate orbits. It follows from Theorem 4.13 that \([W, \varphi)] \rightarrow [(X', \psi')], \) which with Theorem 5.5 implies that \([W, \varphi)] \rightarrow [(X, \psi)]_B \). \( \square \)

6. Fissions of periodic orbits

In this section, as applications of the results built in Section 4, we discuss a kind of invariant sets, which can be obtained by repeatedly 2-fissioning periodic orbits. Before that, we give a generalization of Proposition 4.11

6.1. A generalization of Proposition 4.11

**Definition 6.1.** Let \( \theta \in \mathbb{C}_n \), \( n \geq 2 \) and \( X \) be a nonempty subset of \( \mathbb{R}. \) A continuous map \( \varphi : X \to X \) is said to be \( \theta \)-separable if there exist open intervals \( J_1 < J_2 < \ldots < J_n \) such that \( X \subset \bigcup_{i=1}^n J_n \) and \( \varphi(X \cap J_k) \subset X \cap J_{\theta(k)} \) for \( k = 1, 2, \ldots, n. \)
Let \( f \in C^0(I), x \in I = [a, b] \) and \( \theta \in C_n \). For \( m \geq n \geq 2 \), \( \mathcal{O}_m(x, f) = \{ f^i(x) : i = 0, 1, \ldots, m \} \) is said to be \( \theta \)-separable if there exist intervals \( J_1 < J_2 < \ldots < J_n \) such that \( \mathcal{O}_m(x, f) \subset \bigcup_{i=1}^n J_i \) and \( f(\mathcal{O}_{m-1}(x, f) \cap J_k) \subset \mathcal{O}_m(x, f) \cap J_{\theta(k)} \) for \( k = 1, \ldots, n \).

Obviously, \( \theta \) itself is \( \theta \)-separable. It is easy to see that every doubling of \( \theta \) is \( \theta \)-separable.

**Proposition 6.2.** Let \( \theta \in C_n, n \geq 2 \), and \( (X, \psi) \in \Psi \). If \( \psi \) is \( \theta \)-separable and \( X \) is compact, then \( \psi \Rightarrow \theta \).

**Proof.** Consider any \( f \in C^0(I) \). Assume \( f \) has an invariant set \( S \) with the pattern of \( \psi \). Since \( X \) is compact, by Definitions 4.1 and 6.1 it is easy to verify that there exist closed intervals \( J_1 < J_2 < \ldots < J_n \) such that \( \bigcup_{i=1}^n \partial J_i \subset S \subset \bigcup_{i=1}^n J_i \) and \( f(S \cap J_i) \subset S \cap J_{\theta(i)} \) (\( i = 1, \ldots, n \)). Let \( g \) be a normal reduction of \( f \) relative to \( \mathcal{S} \). Then \( g(J_i) \subset J_{\theta(i)} \) (\( i = 1, \ldots, n \)). Thus there exists \( x \in J_1 \cap P_n(y) \) such that \( \mathcal{O}(x, f) = \mathcal{O}(x, g) \) has the pattern \( \theta \). This implies that \( \psi \Rightarrow \theta \). \( \square \)

The following theorem with Proposition 6.2 is a generalization of Proposition 3.11.

**Theorem 6.3.** Let \( (X, \psi), (Y, \xi) \in \Psi \) and \( \theta \in C \). Suppose that \( \psi \) is \( \theta \)-separable and there exists \( y \in Y \cap \{ \inf Y, \sup Y \} \) such that \( \mathcal{O}(y, \xi) \) is not \( \theta \)-separable. Then \( \theta \Rightarrow \xi \) if and only if \( \psi \Rightarrow \xi \).

**Proof.** By Proposition 6.2 we need only to verify the sufficiency. Without loss of generality, we may assume \( y = \inf Y \in Y \). Let \( n \geq 2 \) be the period of \( \theta \). Suppose \( f \in C^0(I) \) has a periodic orbit \( W = \{ w_1 < w_2 < \ldots < w_n \} \) of pattern \( \theta \). Now we show that \( f \) has an invariant set with the pattern of \( \xi \). Since \( \mathcal{O}(y, \xi) \) is not \( \theta \)-separable, there exists \( m \geq 2n \) such that \( \mathcal{O}_m(y, \xi) \) is not \( \theta \)-separable. Let \( g \in C^0(I) \) be defined by

\[
 g(x) = f(\max\{w_1, \min\{w_n, x\}\}), \quad \text{for any } x \in I.
\]

For any \( r > 0 \), let

\[
 B(g, r) = \{ \varphi \in C^0(I) : |\varphi(x) - g(x)| \leq r \text{ for any } x \in I \},
\]

and

\[
 B(W, r) = \{ x \in I : x \leq w_1, \text{ or } x \geq w_n, \text{ or } |x - w_i| \leq r \text{ for some } i \in \mathbb{Z}_n \}.
\]

By continuity, there exist \( \varepsilon \in (0, \min\{w_i-w_{i-1} : i = 2, 3, \ldots, n\}/3) \) and \( \delta \in (0, \varepsilon/3) \) such that \( \mathcal{O}_{m+n}(z, \varphi) \) is \( \theta \)-separable for any \( \varphi \in B(g, \varepsilon) \) and any \( z \in B(W, \varepsilon) \), and \( \mathcal{O}_n(u, \zeta) \cap \{w_1 - \varepsilon, w_1 + \varepsilon\} \neq \emptyset \) for any \( \zeta \in B(g, 2\delta) \) and any \( u \in B(W, 2\delta) \). Noting \( \psi \) is \( \theta \)-separable, we can construct a map \( \eta \in B(g, 2\delta) \) such that \( \eta(B(W, \delta)) \subset B(W, \delta), \eta(I-B(W,2\delta)) = g(I-B(W,2\delta)) \) and \( \eta|_{B(W,\delta)} \) has an invariant set with the pattern of \( \psi \). Since \( \psi \Rightarrow \xi \), \( \eta \) has an invariant set \( V \) with the pattern of \( \xi \). Let \( v = \min V \). Then \( \mathcal{O}_m(v, \eta) \) is not \( \theta \)-separable. Thus \( v > w_1 + \varepsilon \), and hence \( V \cap B(W, 2\delta) = \emptyset \). This implies \( \eta|_V = g|_V = f|_V \), and hence \( f \) has an invariant set with the pattern of \( \xi \). \( \square \)
6.2. Fissions of periodic orbits.

**Definition 6.4.** Let $I = [a, b]$ and $f \in C^0(I)$. Suppose $W = \{w_1 < w_2 < \ldots < w_n\}$ and $V = \{v_1 < v_2 < \ldots < v_{2n}\}$ are periodic orbits of $f$ with patterns $\gamma$ and $\eta$, respectively. $V$ (or $f|_V$) is called a 2-fission of $W$ (or $f|_W$) if the pattern $\eta$ is a doubling of $\gamma$ and $w_i \in (v_{2i-1}, v_{2i})$ for all $i \in \mathbb{Z}_n$. (See Figure 5.)

**Figure 5**

**Lemma 6.5.** Let $I = [a, b]$, $f \in C^0(I)$ and $W = \{w_1 < w_2 < \ldots < w_n\}$ be a periodic orbit of $f$. Suppose one of the following two conditions holds:

(i) There exists $z \in I$ such that $f^n(z) < w_n < z < f^{2n}(z)$, and $f^{2n}(w_n, z) \subset [w_n, b]$. 

(ii) $W$ is in an odd state under $f$ and there exists a nonempty closed invariant set $S$ of $f$ such that $W \subset L(S) - S$ and $f$ is monotonic on every connected component of $L(S) - S$.

Then there exists a 2-fission $V = \{v_1 < v_2 < \ldots < v_{2n}\}$ of $W$ such that

\[
\mathcal{O}(x, f) \not\subset (w_1, w_n) \quad \text{for any} \quad x \in \bigcup_{i=1}^n (v_{2i-1}, v_{2i}) .
\]

**Proof.** (1) We first assume condition (i) holds. Let $Y = \{x \in [z, b] : f^{2n}(x) = x\}$. Then $Y$ is nonempty and closed, since $f^{2n}(z) \geq z$ and $f^{2n}(b) \leq b$. Let $v = \min Y$ and $w = w_n$. Then

\[
f^{2n}([z, v]) \subset [z, b] \quad \text{and} \quad f^{2n}([w, v]) \subset [w, b].
\]

**Claim.** For any $i \in \mathbb{Z}_{2n-1}$, $f^i(v) < w$.

**Proof of Claim.** If $f^i(v) \geq w$ for some $i \in \mathbb{Z}_{2n-1} - \{n\}$, then it follows from $f^i(v) < w$ that there exists $y \in (w, v]$ such that $f^i(y) = w$ and $f^{2n}(y) = f^{2n-i}(w) < w$, which contradicts (6.2). If $f^n(y) \geq w$, then it follows from $f^n(z) < w$ that there exists $y \in (z, v]$ satisfying $f^n(y) = w$ and $f^{2n}(y) = f^n(w) = w < z$, which also contradicts (6.2). Thus the claim holds.

If the periodic orbit $\mathcal{O}(v, f)$ is not a 2-fission of $W$, then there exist $i$ and $j$ in $\mathbb{Z}_{2n}$ with $i \neq j$ such that $f^i(v) \in (f^j(w); f^j(v)]$. Thus there is $y \in (w, v]$ such that $f^j(y) = f^i(v)$. By the claim, we have $f^{2n}(y) = f^{2n-j+i}(v) < w$. But this contradicts (6.2). Hence $\mathcal{O}(v, f)$ must be a 2-fission of $W$. In particular, the period of $\mathcal{O}(v, f)$ must be $2n$.

Suppose $V = \{v_1 < v_2 < \ldots < v_{2n}\} = \mathcal{O}(v, f)$. Then $v = v_{2n}$. For any $j \in \mathbb{Z}_{2n}$ and any $x \in [f^j(w); f^j(v)]$, there exists $y \in [w, v]$ such that $f^j(y) = x$ and $f^{2n-j}(x) = f^{2n}(y) \in [w, b]$. Thus (6.1) holds.

(2) We now assume that condition (ii) holds. Suppose $(y_n, z_n)$ is the connected component of $L(S) - S$ containing $w (= w_n)$. Let

\[X = \{x \in (y_n, z_n) : f^i(x) \notin S \quad \text{for all} \quad i \in \mathbb{Z}_{2n}\} .\]
Then $X$ is an open set and $w \in X \subset (y_n, z_n)$. Let $X_0$ be the connected component of $X$ containing $w$. Let $z = \sup X_0$. For every $i \in \mathbb{Z}_{2n}$, since $f^i([w, z])$ is in a connected component of $L(S) - S$, $f^i([w, z])$ is monotonic. Noting $W$ is in an odd state, we see that $f^n([w, z])$ is decreasing. Since $f(S) \subset S$, we must have $y_n \leq f^n(z) < w < z \leq z_n = f^{2n}(z)$ and $f^{2n}([w, z]) = [w, z_n] \subset [w, b]$. Hence condition (i) holds. The proof is completed.

□

**Definition 6.6.** Let $(X, \xi) \in \Psi$, $X_0$ be a periodic orbit of $\xi$ with period $m \geq 1$, $\xi_0 = \xi|_{X_0}$, and $n \in \mathbb{N}$.

(1) $\xi$ is called a $(1, 2, 4, \ldots, 2^n)$-fission of $\xi_0$ if there exist periodic orbits $X_0, X_1, \ldots, X_n$ of $\xi$ such that $X = \bigcup_{i=0}^{n} X_i$ and

(i) For every $i \in \mathbb{N}$, the period of $X_i$ is $2^i m$, and $\xi|_{X_i}$ is a 2-fission of $\xi|_{X_{i-1}}$.

(ii) If $n \geq 2$, then $[x; \xi^{2^{i-1}m}(x)] \cap (\bigcup_{j=0}^{i-2} X_j) = \emptyset$ for any $i \in \{2, \ldots, n\}$ and any $x \in X_i$.

(2) $\xi$ is called a $2^n$-fission of $\xi_0$ if there exist periodic orbits $X_0, X_1, X_2, \ldots$ of $\xi$ such that $X = \bigcup_{i=0}^{\infty} X_i$ and for any $i \in \mathbb{N}$, $\xi|_{\bigcup_{j=0}^{i} X_j}$ is a $(1, 2, 4, \ldots, 2^n)$-fission of $\xi$.

**Example 6.7.** Let $X = \mathbb{Z}_7$, $X_0 = \{3\}$, $X_1 = \{2, 6\}$, $X_2 = \{1, 4, 5, 7\}$. Define $\xi : X \to X$ by $\xi(3) = 3$, $\xi(2) = 6$, $\xi(6) = 2$, $\xi(1) = 5$, $\xi(4) = 7$, $\xi(5) = 4$, $\xi(7) = 1$ (see Figure 6). Then $\xi|_{X_i}$ is a 2-fission of $\xi|_{X_{i-1}}$ ($i = 1, 2$). But $\xi$ is not a $(1, 2, 4)$-fission of $\xi|_{X_0}$. From this example we see that condition (i) in Definition 6.6 does not imply condition (ii).

\begin{figure}[h]
\centering
\includegraphics[width=0.5\textwidth]{example67.png}
\caption{Example 6.7}
\end{figure}

**Proposition 6.8.** Let $\xi : X \to X$ be a $2^n$-fission of $\xi_0$ and $X_0, X_1, X_2, \ldots$ be as in Definition 6.6. Suppose the pattern of $\xi_0$ is $\theta \in \mathcal{C}_m$, $m \geq 1$. Then

(i) $\xi|_{[X \setminus \bigcup_{i=0}^{n-1} X_i]}$ is also a $2^n$-fission of $\xi|_{X_0}$ ($n = 1, 2, \ldots$);

(ii) $\xi$ is $\theta$-separable;

(iii) every point in $X$ is an isolated point of $X$.

**Proof.** By Definitions 6.6 and 6.1 (i) and (ii) are obvious. We now check (iii). By (ii), we may consider only the case $m = 1$. Suppose the unique point in $X_0$ is $x_0$. By (i), it suffices to show that $x_0$ is an isolated point of $X$. Suppose $X_1 = \{y_1 < y_2\}, X_2 = \{v_1 < v_2 < y_3 < v_4\}$. Then $v_1 < y_1 < v_2 < x_0 < v_3 < y_2 < v_4$ and $\xi(v_2) \in \{v_3, v_4\}$. If $\xi(v_2) = v_4$, then $\xi(X \cap [y_1, x_0]) \subset [y_2, \sup X)$. By the continuity of $\xi$ at $x_0$, we have $\sup(X \cap [y_1, x_0]) < x_0$, and hence $\inf(X \cap (x_0, y_2)) > x_0$. Thus $x_0$ is an isolated point of $X$. If $\xi(v_2) = v_3$, then $\xi(v_3) = v_1$. By an analogous argument, $x_0$ is still an isolated point of $X$. □
For any \( \theta \in C \), let \( D_0(\theta) = \{ \theta \} \). For \( k = 1, 2, 3, \ldots \), let
\[
D_k(\theta) = \{ \eta \in C : \text{there is } \xi \in D_{k-1}(\theta) \text{ such that } \eta \text{ is a doubling of } \xi \},
\]
and let \( D_k^*(\theta) = \bigcup_{i=0}^{k} D_i(\theta) \). Write \( D_\infty(\theta) = \bigcup_{i=1}^{\infty} D_i(\theta) \). Let \( C(\psi) = \{ \theta \in C : \text{there is some periodic orbit of } \psi \text{ equivalent to } \theta \} \), where \((X, \psi) \in \Psi\).

**Theorem 6.9.** Let \( X \subset \mathbb{R} \) be compact, \((X, \psi) \in \Psi\) and \( \theta \in C \).

(i) Suppose \( C(\psi) \cap D_{n-1}^*(\theta) = \emptyset \), for some \( n \in \mathbb{N} \). Then \( \psi \Rightarrow \theta \) if and only if there exists a \( (1, 2, 4, \ldots, 2^n) \)-fission \( \xi_n \) of \( \theta \) such that \( \psi \Rightarrow \xi_n \).

(ii) Suppose \( C(\psi) \cap D_\infty(\theta) = \emptyset \). Then \( \psi \Rightarrow \theta \) if and only if there exists a \( 2^\infty \)-fission \( \xi \) of \( \theta \) such that \( \psi \Rightarrow \xi \).

**Proof.** The sufficiency is evident. We now prove the necessity. Suppose \( \theta \in C_m \) for some \( m \geq 1 \). Write \( m_i = 2^m \). Let \( I = [a, b] = L[X] \), \( U = I - X \) and let \( f \in C(I) \) be the linear extension of \( \psi \). Assume \( \psi \Rightarrow \theta \). Then \( f \) has a periodic orbit \( W_0 \) of pattern \( \theta \). Since \( C(\psi) \cap D_0(\theta) = \emptyset \), \( W_0 \subset U \). By Lemma 5.1, we may assume \( W_0 \) is in an odd state. By Lemma 6.5, \( f \) has a 2-fission \( V_0 \) of \( W_0 \).

We now assume that, for some \( k \geq 1 \), \( f \) has periodic orbits \( W_0, W_1, \ldots, W_{k-1} \) and \( V_k \) satisfying the following four conditions:

(a) \( f|_{W_0} \) has the same pattern as \( \theta \);
(b) for \( 1 \leq i \leq k-1 \), \( f|_{W_i} \) is a 2-fission of \( f|_{W_{i-1}} \), and \( f|_{V_k} \) is a 2-fission of \( f|_{W_{k-1}} \);
(c) \( f|_{W_0 \cup W_1 \cup \ldots \cup W_{k-1} \cup V_k} \) is a \( (1, 2, 4, \ldots, 2^k) \)-fission of \( f|_{W_0} \);
(d) for \( 0 \leq i \leq k-1 \), \( W_i \subset U \) and \( f|_{W_i} \) is in an odd state.

Since \( C(\psi) \cap D_k(\theta) = \emptyset \), we have \( V_k \subset U \). Let \( V_k = \{ v_{k1} < v_{k2} < v_{k3} < \ldots < v_{km_k} \} \). If \( f|_{V_k} \) is in an even state, then by Lemma 5.1, \( f \) has a periodic orbit \( W_k = \{ v_{k1} < v_{k2} < \ldots < v_{km_k} \} \subset U \) satisfying the following two conditions:

(e) \( f|_{W_0} \) is in an odd state and has the same pattern as \( f|_{V_k} \);
(f) \( \mathcal{O}(x, f) \not\subset \{ v_{km_k} \} \) for any \( x \in \bigcup_{i=1}^{m_k} [v_{ki}; v_{ki}] \), and \([v_{ki}, v_{kj}] \cap [v_{kj}, v_{kj}] = \emptyset \)
for \( 1 \leq i < j \leq m_k \).

It follows from (a)-(f) that \( f|_{W_k} \) is also a 2-fission of \( f|_{W_{k-1}} \), \((\bigcup_{j=1}^{m_k} [v_{kj}+1, v_{kj+1}]) \cap ((\bigcup_{i=0}^{2^k-2} W_i) \cap (\bigcup_{j=0}^{k-1} W_j)) = \emptyset \), and \( f|_{W_k} \) is also a \( (1, 2, 4, \ldots, 2^k) \)-fission of \( f|_{W_0} \). If \( f|_{V_k} \) is in an odd state, then we put \( W_k = V_k \) and \( w_{kj} = v_{kj} \), \( j = 1, 2, \ldots, m_k \). By Lemma 6.5, \( f \) has a periodic orbit \( V_k+1 = \{ v_{k+1,1} < v_{k+1,2} < \ldots < v_{k+1,m_{k+1}} \} \) satisfying
\[
\text{Claim. (I) If } C(\psi) \cap D_{n-1}^*(\theta) = \emptyset, \text{ then } f \text{ has an invariant set } Y_n = W_0 \cup W_1 \cup \ldots \cup W_{n-1} \cup V_n \text{ such that } f|_{Y_n} \text{ is a } (1, 2, 4, \ldots, 2^n) \text{-fission of } f|_{W_n}.
\]
\[
\text{(II) If } C(\psi) \cap D_\infty(\theta) = \emptyset, \text{ then } f \text{ has an invariant set } Y = \bigcup_{j=0}^{\infty} W_j \text{ such that } f|_{Y} \text{ is a } 2^\infty \text{-fission of } f|_{W_0}.
\]
By this claim and Theorem 4.14, one completes the proof of Theorem 6.9. \( \square \)
7. Entropies of patterns of compact line systems

First recall the definition of the topological entropy. Let \((X, f)\) be a compact system. For \(\varepsilon > 0\) and \(n \in \mathbb{N}\), a subset \(W\) of \(X\) is called an \((f, \varepsilon, n)\)-spanning set of \(X\) if for any \(x \in X\) there is \(y \in W\) such that \(d(f^i x, f^i y) < \varepsilon\) for \(1 \leq i \leq n\). Let \(\text{Span}(f, \varepsilon, n)\) denote the smallest cardinality of any \((f, \varepsilon, n)\)-spanning set of \(X\).

Then the \textbf{topological entropy} of \((X, f)\) is defined by

\[
h(X, f) = \lim_{\varepsilon \to 0} \lim_{n \to \infty} \frac{1}{n} \log \text{Span}(f, \varepsilon, n).
\]

See [1] [9] [11], etc. for equivalent definitions and more information about the topological entropy.

**Definition 7.1.** Let \((X, \psi)\) be a line system, and \(I = L(X)\). Define

\[
h^*((X, \psi)) = \inf\{h(I, f) : f \in C^0(I) \text{ and } f|_X = \psi\},
\]

\[
h^*([X, \psi]) = \inf\{h^*(Y, \xi) : Y, \xi \in \{[X, \psi]\}\}.
\]

\(h^*([X, \psi])\) is called the \textbf{topological entropy of the pattern} \([X, \psi]\).

When \((X, \psi)\) is a periodic orbit, \(h^*([X, \psi]) = h^*(X, \psi)\) is extensively studied by many authors and there are many interesting results (for example, see [1] [7] [8] [9] [11]). It is shown that, for any periodic orbit \((X, \psi)\), \(h^*(X, \psi)\) is the entropy of its linear extension. The following lemma is also well known; see [1].

**Lemma 7.2.** Let \(f : I \to I\) be an interval map. Then

\[
h(I, f) = \sup\{h^*(P, f|_P) : P \text{ is a periodic orbit of } f\}\).
\]

For an interval map, the topological entropy is also closely related to its minimal subsets, which is discussed in [14]. We now give a theorem, which is a generalization of the corresponding results on patterns of periodic orbits.

**Theorem 7.3.** Let \((X, \psi)\) be a compact line system, \(I = L(X)\), and \(f\) be a monotonic extension of \(\psi\). Then \(h^*([X, \psi]) = h^*(X, \psi) = h(I, f)\).

**Proof.** It follows from Definition [7.1] that \(h^*([X, \psi]) \leq h^*(X, \psi) \leq h(I, f)\). Hence, it suffices to show \(h^*([X, \psi]) \geq h(I, f)\). Consider any given real number \(r < h(I, f)\) and any interval map \(g : J \to J\) exhibiting \((X, \psi)\). Since, by Lemma [7.2] \(h(I, f) = \sup\{h^*(P, f|_P) : P \text{ is a periodic orbit of } f\}\), there is a periodic orbit \(P\) of \(f\) such that \(h^*(P, f|_P) > r\). By Theorem [5.2] \(g\) exhibits \((P, f|_P)\), and hence, by Lemma [7.2] again, one has \(h(J, g) \geq h^*(P, f|_P) > r\). This means that \(h^*([X, \psi]) \geq h(I, f)\). \(\square\)

By Theorem [7.3] we obtain the following corollary immediately.

**Corollary 7.4.** (1) Let \((X, \psi)\) be a compact line system, \(I = L(X)\), and \(f\) and \(g\) be two monotonic extensions of \(\psi\). Then \(h(I, f) = h(I, g)\).

(2) Let \((X, \psi)\) and \((Y, \xi)\) be two compact line systems which have the same pattern. Then \(h^*(X, \psi) = h^*(Y, \xi)\).

**Acknowledgment**

We would like to thank the referees for a very thorough reading and many helpful corrections and suggestions concerning this paper.
