SYSTEMS FORMED BY TRANSLATES
OF ONE ELEMENT IN $L_p(\mathbb{R})$

E. ODELL, B. SARI, TH. SCHLUMPRECHT, AND B. ZHENG

Abstract. Let $1 \leq p < \infty$, $f \in L_p(\mathbb{R})$, and $\Lambda \subseteq \mathbb{R}$. We consider the closed subspace of $L_p(\mathbb{R})$, $X_p(f, \Lambda)$, generated by the set of translations $f(\lambda)$ of $f$ by $\lambda \in \Lambda$. If $p = 1$ and $\{f(\lambda) : \lambda \in \Lambda\}$ is a bounded minimal system in $L_1(\mathbb{R})$, we prove that $X_1(f, \Lambda)$ embeds almost isometrically into $\ell_1$. If $\{f(\lambda) : \lambda \in \Lambda\}$ is a bounded minimal system in $L_p(\mathbb{R})$, then $\{f(\lambda) : \lambda \in \Lambda\}$ is equivalent to the unit vector basis of $\ell_p$ for $1 \leq p \leq 2$ and $X_p(f, \Lambda)$ embeds into $\ell_p$ if $2 < p \leq 4$. If $p > 4$, there exists $f \in L_p(\mathbb{R})$ and $\Lambda \subseteq \mathbb{R}$ so that $\{f(\lambda) : \lambda \in \Lambda\}$ is unconditional basic and $L_p(\mathbb{R})$ embeds isomorphically into $X_p(f, \Lambda)$.

1. Introduction

Let $f : \mathbb{R} \to \mathbb{R}$ and $\lambda \in \mathbb{R}$. We denote by $f(\lambda)$ the translation of $f$ $\lambda$-units to the right for $\lambda > 0$ (and $|\lambda|$-units to the left for $\lambda < 0$). Precisely, $f(\lambda)(x) = f(x - \lambda)$ for $x \in \mathbb{R}$.

If $f \in L_p(\mathbb{R})$, $1 \leq p < \infty$ and $\Lambda \subseteq \mathbb{R}$, we let $X_p(f, \Lambda)$ equal $\{\{f(\lambda) : \lambda \in \Lambda\}\}$, where $\{\cdot\}$ denotes the closed linear span in $L_p(\mathbb{R})$. Our main focus shall be on the nature of such subspaces given that $\{f(\lambda) : \lambda \in \Lambda\}$ has some additional structure and $\Lambda$ is uniformly discrete, i.e.,

$$\inf\{|\lambda - \lambda'| : \lambda, \lambda' \in \Lambda, \lambda \neq \lambda'\} > 0.$$ 

The “additional structure” takes several forms: $\{f(\lambda) : \lambda \in \Lambda\}$ is a bounded minimal system or is unconditional basic or can be ordered to be a (Schauder) basis or a (Schauder) frame for $X_p(f, \Lambda)$. It is worth mentioning that it is known that if $\{f(\lambda) : \lambda \in \Lambda\}$ is a bounded minimal system, in particular, if it can be ordered to be basic, then $\Lambda$ must be uniformly discrete. This is easy (Proposition 1.8 below).

The nature of $X_p(f, \Lambda)$ and $\{f(\lambda) : \lambda \in \Lambda\}$ have been studied in a number of papers, mainly using techniques of harmonic analysis. Our techniques will be, largely, from the geometry of Banach spaces. We recall seven theorems, beginning with Wiener’s famous Tauberian theorem.

Theorem 1.1 ([Wi]). For $f \in L_2(\mathbb{R})$, $X_2(f, \mathbb{R}) = L_2(\mathbb{R})$ if and only if $\hat{f}(t) \neq 0$ a.e. For $f \in L_1(\mathbb{R})$, $X_1(f, \mathbb{R}) = L_1(\mathbb{R})$ if and only if $\hat{f}(t) \neq 0$ for all $t \in \mathbb{R}$.
Theorem 1.2 ([AO] Theorem 2.1). Let $2 < p < \infty$. There exists $f \in L_p(\mathbb{R})$, all of whose derivatives exist and are in $L_2(\mathbb{R})$ (i.e., $f \in H^{2,\infty}(\mathbb{R})$) so that $X_p(f, \mathbb{Z}) = L_p(\mathbb{R})$. Moreover, $f$ can be chosen to satisfy, in addition, any one of the following conditions:

1. $X_p(f, \mathbb{N} \cup \{0\}) = L_p(\mathbb{R})$.
2. $(f_{(n)})_{n \in \mathbb{Z}}$ is orthogonal in $L_2(\mathbb{R})$.
3. $(f_{(n)})_{n \in \mathbb{Z}}$ is a bounded minimal system.

Theorem 1.3 ([AO]). Let $1 \leq p \leq 2$, and let $F \subseteq L_p(\mathbb{R})$ be a finite set. Then $\{f_{(n)} : f \in F, n \in \mathbb{Z}\} \neq L_p(\mathbb{R})$.

Theorem 1.4 ([ER] Corollary 2.11). Let $1 \leq p < \infty$, $0 \neq f \in L_p(\mathbb{R})$. Then $\{f_{(\lambda)} : \lambda \in \mathbb{R}\}$ is linearly independent.

Theorem 1.5 ([O]). Let $\Lambda = \{\lambda_n\}_{n \in \mathbb{Z}} \subseteq \mathbb{R}$ so that $\Lambda \cap \mathbb{Z} = \emptyset$ and $\lim_{|n| \to \infty} |\lambda_n - n| = 0$. Then there exists $f \in L_2(\mathbb{R})$ so that $X_2(f, \Lambda) = L_2(\mathbb{R})$.

Theorem 1.6 ([OZ Theorem 2]). There is no unconditional basis of translates of $f$, $\{f_{(\lambda)} : \lambda \in \Lambda\}$, with $X_2(f, \Lambda) = L_2(\mathbb{R})$.

So the space $X_p(f, \Lambda)$, $\Lambda$ uniformly discrete, can equal $L_p(\mathbb{R})$, for $p \geq 2$ at least. For $p = 1$ the situation is different as pointed out to us by J. Bruna.

Theorem 1.7. Let $f \in L_1(\mathbb{R})$, and let $\Lambda \subseteq \mathbb{R}$ be uniformly discrete. Then $X(f, \Lambda) \neq L_1(\mathbb{R})$.

This seems to be a folklore theorem and we were unable to find a reference. It follows from Theorem 1.1 and Lemma 5.3 below (and can also be deduced from [BOU] and the proof of Lemma 5.3).

For $1 < p < \infty$ it remains an open problem whether there exists $\Lambda \subseteq \mathbb{R}$ and $f \in L_p(\mathbb{R})$ so that, in some order, $\{f_{(\lambda)} : \lambda \in \Lambda\}$ is a basis for $L_p(\mathbb{R})$.

In section 2 we prove that if $f \in L_1(\mathbb{R})$ and $\{f_{(\lambda)} : \lambda \in \Lambda\}$ is a bounded minimal system for $X_1(f, \Lambda)$, then $X_1(f, \Lambda)$ embeds almost isometrically into $\ell_1$. The same conclusion holds if $\Lambda$ is uniformly discrete and $\{f_{(\lambda)} : \lambda \in \Lambda\}$ can be ordered to be a (Schauder) frame for $X_1(f, \Lambda)$.

In Corollary 2.10 we show that for $1 \leq p \leq 2$, if $(f_{(\lambda)})_{\lambda \in \Lambda}$ is an unconditional basic sequence, then $(f_{(\lambda)})_{\lambda \in \Lambda}$ is equivalent to the unit vector basis of $\ell_p$. For $2 < p \leq 4$, we show (Theorem 2.11) that if $(f_{(\lambda)})_{\lambda \in \Lambda}$ is unconditional basic, then $X_p(f, \Lambda)$ embeds isomorphically into $\ell_p$ but (Proposition 2.13) $(f_{(\lambda)})_{\lambda \in \Lambda}$ need not be equivalent to the unit vector basis of $\ell_p$. For $4 < p < \infty$, we give an example (Theorem 2.14) of an unconditional basic sequence $(f_{(\lambda)})_{\lambda \in \Lambda}$ so that $X_p(f, \Lambda)$ contains an isomorph of $L_p[0, 1]$ (which, of course, is isometric to $L_p(\mathbb{R})$).

Among further results in section 2, we also consider the translation problem for the translation invariant space $L_p(\mathbb{R}) \cap L_2(\mathbb{R})$, $2 < p < \infty$, and show (Proposition 2.13) that if $(f_{(\lambda)})_{\lambda \in \Lambda}$ is unconditional basic, then it is equivalent to the unit vector basis of $\ell_2$.

In the beginning of section 3, we revisit the problem for integer translates of $f \in L_1(\mathbb{R})$. We also prove that if $f \in L_1(\mathbb{R})$ with $f(t) \neq 0$ for all $t$, then $X_1(f, \mathbb{Z})$ embeds into $\ell_1$ (Proposition 3.3). We also consider discrete versions of our problem for $\ell_p(\mathbb{Z}, X)$ in Propositions 3.3 and 3.7 and Corollary 3.12. Fourier analysis plays a role in some of these results.
In section 4, we recall some additional known results from the literature and list some remaining open problems.

We use standard Banach space notation as may be found in [LT] or [JL]. Background material on bases, unconditional bases and such can be found there. For the benefit of those less familiar with these notions, we recall some definitions and facts. A biorthogonal system is a sequence \((x_i, x_i^*)_{i=1}^{\infty} \subseteq X \times X^*\) where \(x_i^* (x_j) = \delta_{i,j}\). A biorthogonal system \((x_i, x_i^*)_{i=1}^{\infty} \subseteq X \times X^*\) is fundamental (or complete) if \(\{(x_i)_i\} = X\) and bounded if \(\sup_i \|x_i\| \|x_i^*\| < \infty\).

\((x_i, x_i^*)_{i=1}^{\infty} \subseteq X\) is a minimal system if there exists \((x_i^*)_{i=1}^{\infty} \subseteq X^*\) so that \((x_i, x_i^*)_{i=1}^{\infty}\) is a biorthogonal system. This is equivalent to \(x_i \notin \{x_j : j \neq i\}\) for all \(i \in \mathbb{N}\). \((x_i)_{i=1}^{\infty}\) is a bounded minimal system if, in addition, \((x_i, x_i^*)_{i=1}^{\infty}\) is a bounded biorthogonal system. This is equivalent to \(\inf_i \text{dist}(x_i, \{x_j : j \neq i\}) > 0\). \((x_i)_{i=1}^{\infty} \subseteq X\) is a (Schauder) basis for \(X\) if for all \(x \in X\) there exists a unique sequence of scalars \((a_i)_{i=1}^{\infty}\) so that \(x = \sum_{i=1}^{\infty} a_i x_i\). This is equivalent to saying that all \(x_i \neq 0\), \([x_i]\) \(= X\) and for some \(K < \infty\), all \(m < n \in \mathbb{N}\) and all \((a_i)_{i=1}^{\infty} \subseteq \mathbb{R}\), \(\sum_{i=1}^{\infty} a_i x_i || \leq K \sum_{i=1}^{\infty} a_i ||x_i||\). The smallest such \(K\) is the basis constant of \((x_i)\). A basis \((x_i)_{i=1}^{\infty}\) for \(X\) is a fundamental bounded minimal system for \(X\). In this case every \(x \in X\) can be written uniquely as \(x = \sum_{i=1}^{\infty} x_i^* (x_i)\). The \(x_i^*\)'s are a basic sequence in \(X^*\), i.e., form a basis for \([x_i^*]\) \(\subseteq X^*\), and are a basis for \(X^*\) if \(X\) is reflexive. \((x_i)_{i=1}^{\infty}\) is an unconditional basis for \(X\) if for all \(x \in X\) there exists a unique sequence of scalars \((a_i)_{i=1}^{\infty}\) so that \(x = \sum_{i=1}^{\infty} a_i x_i\) and the convergence is unconditional, i.e., \(x = \sum_{i=1}^{\infty} a_{\pi(i)} x_{\pi(i)}\) for all permutations \(\pi\) of \(\mathbb{N}\). This is equivalent to all \(x_i\)'s \(\neq 0\), \([x_i]\) \(= X\) and

\[
\sup \left\{ \left\| \sum_{i=1}^{\infty} \varepsilon_i a_i x_i \right\| : \sum_{i=1}^{\infty} a_i x_i \in B_X \text{ and } \varepsilon_i = \pm 1 \text{ for all } i \right\} < \infty.
\]

Here \(B_X\) denotes the closed unit ball of \(X\). This number is called the unconditional basis constant of \((x_i)_{i=1}^{\infty}\). The biorthogonal functionals then form an unconditional basic sequence in \(X^*\).

A block basis \((y_i)_{i=1}^{\infty}\) of a basic sequence \((x_i)_{i=1}^{\infty}\) is a non-zero sequence given by

\[
y_i = \sum_{j=n_{i-1}+1}^{n_i} a_j x_j \text{ for some sequence } n_0 < n_1 < n_2 < \cdots
\]

in \(\mathbb{N}_0\) and scalars \((a_j)_{j=1}^{\infty} \subseteq \mathbb{R}\). A block basis is a basic sequence, which is unconditional basic if the \(x_i\)'s are unconditional basic. A sequence \((x_i)\) is semi-normalized if \(0 < \inf \|x_i\| \leq \sup_i \|x_i\| < \infty\).

A Schauder frame for a Banach space \(X\) is a sequence \((x_i, f_i)_{i=1}^{\infty} \subseteq X \times X^*\) such that for all \(x \in X\), \(x = \sum_{i=1}^{\infty} f_i (x) x_i\). Of course every basis for \(X\) is a frame for \(X\) and just as in the basis case, the uniform boundedness principle yields

\[
\sup \| \sum_{i=1}^{n} f_i (x) x_i \| : n \in \mathbb{N}, x \in S_X \}< \infty \text{ (called the frame constant)}
\]

where \(S_X = \{x \in X : \|x\| = 1\}\) is the unit sphere of \(X\). More on frames can be found in [CHL] and [CDOSZ]. Schauder frames should not be confused with Hilbert frames, which are much more restrictive. Note that for frames, \((x_i, f_i)\) is not assumed to be a biorthogonal sequence.

In our situation, where we are concerned with \((f_i)_{i=1}^{\infty}\) being a sequence of uniformly discrete translations of some \(f \in L_p(\mathbb{R})\), we do not know of an example where \((f_i)\) is a frame but is not basic. However, many of our results would hold.
only given the property of Proposition 2.1 below and so we have stated them in terms of frames.

Some background material on $L_p$ spaces which we shall use can be found in [AOD] and in the basic concepts chapter of [JL]. In particular we shall use that a normalized unconditional basic sequence $(f_i)$ in $L_p(\mathbb{R})$ satisfies for constants $A_p$ and $B_p$, depending on $p$ and the unconditional basis constant of $(f_i)$,

(1.1) For $1 \leq p \leq 2$, for all $(a_i) \subseteq \mathbb{R}$,

$$A_p^{-1} \left( \sum_{i=1}^{\infty} a_i^2 \right)^{1/2} \leq \left\| \sum_{i=1}^{\infty} a_i f_i \right\|_p \leq B_p \left( \sum_{i=1}^{\infty} |a_i|^p \right)^{1/p} .$$

(1.2) For $2 < p < \infty$, $(a_i) \subseteq \mathbb{R}$,

$$A_p^{-1} \left( \sum_{i=1}^{\infty} |a_i|^p \right)^{1/p} \leq \left\| \sum_{i=1}^{\infty} a_i f_i \right\|_p \leq B_p \left( \sum_{i=1}^{\infty} |a_i|^2 \right)^{1/2} .$$

If $(f_i)$ is unconditional basic in $L_p[0,1]$, $1 \leq p < \infty$, then for some $C_p$, depending on $p$ and the unconditional basis constant of $(f_i)$, for all $(a_i) \subseteq \mathbb{R}$,

(1.3) (Square function inequality)

$$\left\| \sum_{i=1}^{\infty} a_i f_i \right\|_p \overset{C_p}{\lesssim} \left( \int_0^1 \left( \sum_{i=1}^{\infty} |a_i|^2 f_i(t)^2 \right)^{p/2} dt \right)^{1/p} .$$

Here we use “$A \lesssim B$” to denote $A \leq CB$ and $B \leq CA$.

The Haar basis $(h_n)_{n=1}^{\infty}$ is a basis for $L_1[0,1]$. This sequence is given by

$$(h_n)_{n=1}^{\infty} = (X_{0,1}, X_{0,1/2} - X_{1/2,1}, X_{0,1/4} - X_{1/4,1/2}, \ldots, X_{1/2,3/4} - X_{3/4,1}, X_{0,1/8} - X_{1/8,1/4}, \ldots) .$$

The same system is an unconditional basis for $L_p[0,1]$, $1 < p < \infty$. Usually, below, we will let $(h_n)_{n=1}^{\infty}$ refer to the normalized Haar basis, i.e., $(h_n/\|h_n\|_p)_{n=1}^{\infty}$. We can get an unconditional basis for $L_p(\mathbb{R})$ from this by copying $(h_n)_{n=1}^{\infty}$ onto each interval $[k,k+1]$, $k \in \mathbb{Z}$. In this case we will have functions $(h_n,k)_{n \in \mathbb{N}}$, $k \in \mathbb{Z}$, and we will presume they are linearly ordered so as to be compatible with the Haar basis ordering on each $[k,k+1]$, i.e., if the functions are ordered as $(x_i)_{i=1}^{\infty}$ and if $x_i = h_n,k$, $x_j = h_m,k$ with $i < j$, then $n < m$. This ordering yields that if $(g_i)_{i=1}^{\infty}$ is a block basis of the Haar basis, then $(g_i\|_{[n,m]})_{i=1}^{\infty}$ is also a block basis of the Haar basis (well, some $g_i$’s could be 0 here) for all integers $n < m$.

The Rademacher sequence $(r_n)_{n=1}^{\infty}$ is given by $(r_n)_{n=1}^{\infty} = (h_1, h_2, h_3 + h_4, h_5 + \cdots + h_8, \ldots)$, where the $h_n$’s refer to the non-normalized Haar functions. The classical Khintchine’s inequality asserts that it is equivalent to the unit vector basis of $\ell_2$ in all $L_p[0,1]$ spaces, $1 \leq p < \infty$, i.e.,

$$\left\| \sum_{i=1}^{\infty} a_i r_i \right\|_p \overset{K_p}{\lesssim} \left( \sum_{i=1}^{\infty} |a_i|^2 \right)^{1/2} .$$

One reason for taking $\Lambda$ to be uniformly discrete in our considerations is, as mentioned above, given by the easy

**Proposition 1.8 (OZ Theorem 1).** Let $1 \leq p < \infty$, and let $(f_i,g_i)_{i=1}^{\infty}$ be a bounded biorthogonal system in $L_p(\mathbb{R})$ so that for some $f \in L_p(\mathbb{R})$ and $(\lambda_i)_{i=1}^{\infty} \subseteq \mathbb{R}$, $f_i = f(\lambda_i)$ for all $i$. Then $\Lambda = (\lambda_i)_{i=1}^{\infty}$ is uniformly discrete.
Proof. If not, there exist subsequences \((i_m)\) and \((j_m)\) of \(\mathbb{N}\) so that
\[
\lim_{m \to \infty} |\lambda_{i_m} - \lambda_{j_m}| = 0
\]
and \(\lambda_{i_m} \neq \lambda_{j_m}\) for all \(m\). Then
\[
\|g_{i_m}\| \geq \frac{|\langle g_{i_m}, f_{i_m} - f_{j_m} \rangle|}{\|f_{i_m} - f_{j_m}\|_p} = \frac{1}{\|f_{i_m} - f_{j_m}\|_p},
\]
and the latter is unbounded in \(m\), a contradiction. \(\Box\)

2. Main results

We begin with the elementary but very useful

**Proposition 2.1.** Let \(\Lambda \subseteq \mathbb{R}\) be uniformly discrete, \(1 \leq p < \infty\), and \(f \in L_p(\mathbb{R})\). Then for all intervals \(I = [a, b]\),
\[
\sum_{\lambda \in \Lambda} \|f(\lambda)|I| \|_p = \sum_{\lambda \in \Lambda} \int_I |f(t - \lambda)|^p dt \leq \sum_{\lambda \in \Lambda} \int_{a+(\ell-1)e_0}^{\ell e_0 - \lambda} |f(t)|^p dt \leq \|f\|_p^2,
\]
since the intervals of integration are disjoint for \(\lambda \in \Lambda\). Thus
\[
\sum_{\lambda \in \Lambda} \|f(\lambda)|I| \|_p \leq \frac{b-a}{e_0} \|f\|_p^2.
\]

We note a simple consequence of Proposition 2.1. We remark that in [AO, Theorem 4.1], it is proved that if \(1 < p < \infty\) and \(f \in L_p(\mathbb{R}) \cap L_1(\mathbb{R})\), then \(X_p(f, \mathbb{Z}) \neq L_p(\mathbb{R})\).

**Proposition 2.2.** Let \(1 < p < \infty\), \(f \in L_p(\mathbb{R}) \cap L_1(\mathbb{R})\), and let \((f_i)_{i=1}^\infty\) be a sequence of uniformly discrete translates of \(f\). Then \((f_i)_{i=1}^\infty\) is not a fundamental bounded minimal system for \(L_p(\mathbb{R})\). Furthermore, there is no sequence \((g_i)_{i=1}^\infty \subseteq L_q(\mathbb{R})\) \((1/p + 1/q = 1)\) so that \((f_i, g_i)_{i=1}^\infty\) is a frame for \(L_p(\mathbb{R})\).

**Proof.** Assume \((f_i, g_i)\) are in fact such a frame. \(\|f_i\|_p = \|f\|_p\) for all \(i\) and thus \((g_i)_{i=1}^\infty) is \(\omega^*\)-null and hence bounded in \(L_q(\mathbb{R})\). Let \(K = \sup_{i} \|g_i\|_q\). Choose \(n_0 \in \mathbb{N}\) with
\[
\sum_{j=n_0+1}^\infty \|f_i|_{[0,1]}\|_1 < \frac{1}{4K}.
\]
Choose \(h : \mathbb{R} \to \mathbb{R}\) so that \(|h| = \chi_{[0,1]}\) and \(|(h, g_i)| < \frac{1}{4n_0 t \|f\|_q}\) for \(i \leq n_0\) \((h\) could be a Rademacher function). Thus \(\|h\|_p = \|h\|_1 = 1\). Also \(h = \sum_{i=1}^\infty \langle h, g_i \rangle f_i\), the series converging in \(L_p(\mathbb{R})\), and so
\[
h|_{[0,1]} = \sum_{i=1}^\infty \langle h, g_i \rangle f_i|_{[0,1]},
\]
the series converging in $L_1[0,1]$. Then

$$1 = \|h\|_1 \leq \sum_{i=1}^{\infty} |\langle h, g_i \rangle| \|f_i|_{[0,1]}\|_1$$

$$\leq \sum_{i=1}^{n_0} |\langle h, g_i \rangle| \|f\|_1 + \sum_{i=n_0+1}^{\infty} \|g_i\|_q \|f_i|_{[0,1]}\|_1$$

$$< \frac{n_0}{4n_0\|f\|_1} \|f\|_1 + \sup_{i} \|g_i\|_q \frac{1}{4K} = \frac{1}{2},$$

a contradiction.

The argument is similar if we assume that $(f_i, g_i)_{i=1}^{\infty}$ is a fundamental bounded biorthogonal system for $L_p(\mathbb{R})$. Then, for the same $h$, $n_0$ and for $\varepsilon > 0$ arbitrary, we can choose $f = \sum_{i=1}^{n} a_i f_i$ with $\|h - f\|_p < \varepsilon$. Thus $\|f|_{[0,1]} - h\|_1 < \varepsilon$ and

$$1 - \varepsilon \leq \|f|_{[0,1]}\|_1 \leq \sum_{i=1}^{n_0} |a_i| \|f_i|_{[0,1]}\|_1 + \sum_{i=n_0+1}^{n} |a_i| \|f_i|_{[0,1]}\|_1 .$$

For $i \leq n_0$, $|a_i| = |g_i(f)| \leq |g_i(f - h)| + |g_i(h)| < K\varepsilon + \frac{1}{4n_0\|f\|_1}$. For $i > n_0$, $|a_i| \leq K(1 + \varepsilon)$. Hence by (2.1)

$$1 - \varepsilon \leq n_0 \left( K\varepsilon + \frac{1}{4n_0\|f\|_1} \right) \|f\|_1 + \sum_{i=n_0+1}^{n} K(1 + \varepsilon) \|f_i|_{[0,1]}\|_1$$

$$< n_0 K\varepsilon \|f\|_1 + \frac{1}{4} + \frac{1}{4}(1 + \varepsilon) < \frac{3}{4} < 1 - \varepsilon ,$$

a contradiction, if $\varepsilon < 1/4$. \hfill \Box

For $p = 1$ we have a stronger result (Corollary 2.4) as a consequence of our next theorem.

**Definition.** Let $1 \leq p < \infty$, $1/p + 1/q = 1$.

a) Let $(f_i, g_i) \subseteq L_p(\mathbb{R}) \times L_q(\mathbb{R})$ be a frame for a subspace $X$ of $L_p(\mathbb{R})$. We say $(f_i, g_i)$ satisfies (\ast) if

\[
(\ast) \quad \text{for all } \varepsilon > 0 \text{ and all bounded intervals } I \subseteq \mathbb{R}, \text{ there exists } n \in \mathbb{N} \text{ so that for all } m \geq n \text{ and } f \in X,
\]

\[
\left\| \sum_{i=m+1}^{\infty} \langle f, g_i \rangle f_i |_I \right\|_p \leq \varepsilon \|f\|_p .
\]

b) A semi-normalized bounded minimal system $(f_i)_{i=1}^{\infty}$ in $L_p(\mathbb{R})$ satisfies (\ast\ast) if

\[
(\ast\ast) \quad \text{for all } \varepsilon > 0 \text{ and bounded intervals } I \subseteq \mathbb{R} \text{ there exists } n \in \mathbb{N} \text{ so that for all } n < m \leq m_1 \leq m_2 \text{ and } f = \sum_{i=1}^{m_2} a_i f_i \text{ with } \|f\|_p = 1 , \| \sum_{i=m_1}^{m_2} a_i f_i |_I \| \leq \varepsilon .
\]

**Theorem 2.3.** Let $(f_i, g_i)_{i=1}^{\infty}$ be a frame or a semi-normalized bounded fundamental minimal system for a subspace $X$ of $L_p(\mathbb{R})$, $1 \leq p < \infty$, satisfying (\ast) or (\ast\ast), respectively. Then $X$ embeds almost isometrically into $\ell_p$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
That $X$ embeds almost isometrically into $\ell_p$ means that for all $\varepsilon > 0$ there exists $T : X \to \ell_p$ with $(1+\varepsilon)^{-1} \leq \|Tf\| \leq 1+\varepsilon$ for all $f \in S_X$. The proof of Theorem 2.3 will yield, for all $\varepsilon > 0$, a partition $\Pi = (D_s)_{s=1}^\infty$ of $\mathbb{R}$ into intervals so that for all $f \in S_X$,

$$
\|f - \mathbb{E}_\Pi f\|_p < \varepsilon .
$$

$\mathbb{E}_\Pi$ is the conditional expectation projection

$$
f \mapsto \sum_{s=1}^\infty \left( \int_{D_s} f \right) \frac{\chi_{D_s}}{m(D_s)} .
$$

Of course, in $L_p$, $(\frac{\chi_D}{m(D)})$ is 1-equivalent to the unit vector basis of $\ell_p$.

From Proposition 2.1 and Theorem 2.3 we obtain

**Corollary 2.4.** If $(f_i, g_i)$ is a frame or a fundamental bounded minimal system for a subspace $X$ of $L_1(\mathbb{R})$ where the $f_i$’s are uniformly discrete translates of some $f \in L_1(\mathbb{R})$, then $X$ embeds almost isometrically into $\ell_1$.

**Proof of Theorem 2.3.** We first consider the frame case and let $C$ be the frame constant. Thus for all $f \in X$ and $n \in \mathbb{N}$,

$$
\left\| \sum_{i=1}^n \langle f, g_i \rangle f_i \right\|_p \leq C \|f\|_p .
$$

Let $\varepsilon > 0$. We inductively choose increasing sequences $(m_k)$ and $(n_k)$ in $\mathbb{N}$ to obtain, where $I_k = [-m_k, m_k]$,

(2.2) for $f \in X$, and $n \geq n_k$,  \[ \left\| \sum_{i=n+1}^\infty \langle g_i, f \rangle f_i \right\|_p \leq \varepsilon 2^{-k} \|f\|_p , \]

(2.3) for $f \in \text{span}\{f_i : i \leq n_k\}$,  \[ \|f|_{\ell_\infty} \leq \varepsilon 2^{-k} \|f\|_p . \]

We do this by setting $I_0 = \emptyset$, letting $n_1$ be arbitrary, and choosing $m_1$ to satisfy (2.3) for $k = 1$. Then we choose $n_2$ to satisfy (2.2) using (*) and continue in this manner. We let $A_k = I_k \setminus I_{k-1}$, for $k \in \mathbb{N}$.

Choose a partition $\pi_k$ of $A_k$ into intervals, $k \geq 1$, so that for all $f \in \text{span}\{f_i : i \leq n_{k+1}\}$,

(2.4)  \[ \left\| f|_{A_k} - \sum_{D \in \pi_k} \frac{\chi_D}{m(D)} \int_D f(x) \, dx \right\|_p \leq \varepsilon 2^{-k} \|f\|_p . \]

Let $f \in X$ with $\|f\|_p = 1$. Then, with $n_0 = 0$,

$$
1 = \left\| \sum_{i=1}^\infty \langle g_i, f \rangle f_i \right\|_p = \left\| \sum_{s=1}^\infty \left( \sum_{i=n_{s+1}+1}^{n_s} \langle g_i, f \rangle f_i |_{I_s} \right) + \sum_{s=1}^\infty \left( \sum_{i=n_{s-1}+1}^{n_s} \langle g_i, f \rangle f_i |_{\mathbb{R} \setminus I_s} \right) \right\|_p .
$$

\[ \leq \left\| \sum_{s=1}^\infty \sum_{i=n_{s-1}+1}^{n_s} \langle g_i, f \rangle f_i |_{I_s} \right\|_p + 2C \varepsilon , \text{ by (2.3)} \]

\[ \leq \left\| \sum_{s=1}^\infty \sum_{i=n_{s-1}+1}^{n_s} \langle g_i, f \rangle f_i |_{I_s \setminus I_{s-1}} \right\|_p + 2C \varepsilon + 2 \varepsilon , \text{ by (2.2)} .
$$
where we let $I_{-1} = I_0 = \emptyset$

$$= \left\| \sum_{s=1}^{\infty} \sum_{i=n_{s-1}+1}^{n_s} \langle g_i, f \rangle |_{A_s \cup A_{s-1}} \right\|_p + 2C\varepsilon + 2\varepsilon,$$

where we let $A_0 = \emptyset$

$$= \left\| \sum_{s=1}^{\infty} \chi_{A_s} \sum_{i=n_{s-1}+1}^{n_s+1} \langle g_i, f \rangle f_i \right\|_p + 2C\varepsilon + 2\varepsilon$$

(2.5) \[ \leq \left( \sum_{s=1}^{\infty} \sum_{D \in \pi_s} \left| \int_D \sum_{i=n_{s-1}+1}^{n_s+1} \langle g_i, f \rangle f_i(x) \, dx \right|^p \right)^{1/p} + 4C\varepsilon + 2\varepsilon \text{ by (2.4)}.

Now by (2.2) for $s \in \mathbb{N},$

(2.6) \[ \left( \sum_{D \in \pi_s} \left| \int_D \sum_{i=n_{s-1}+1}^{n_s+1} \langle g_i, f \rangle f_i(x) \, dx \right|^p \right)^{1/p} \leq \sum_{i=n_{s-1}+1}^{n_s+1} \langle g_i, f \rangle f_i \right\|_p \leq \varepsilon 2^{-(s+1)}.

If $s > 1,$ then by (2.3),

(2.7) \[ \left( \sum_{D \in \pi_s} \left| \int_D \sum_{i=1}^{n_s-1} \langle g_i, f \rangle f_i(x) \, dx \right|^p \right)^{1/p} \leq 2^{-s+1}C\varepsilon.

From (2.5), (2.6), and (2.7), we obtain that

$$1 = \|f\|_p \leq \left( \sum_{D \in \bigcup_{s=1}^{\infty} \pi_s} \left| \int_D f(x) \, dx \right|^p \right)^{1/p} + \sum_{s=1}^{\infty} \varepsilon 2^{-(s+1)} + \sum_{s=2}^{\infty} 2^{-s+1}C\varepsilon + 6C\varepsilon$$

$$\leq \left( \sum_{D \in \bigcup_{s=1}^{\infty} \pi_s} \left| \int_D f(x) \, dx \right|^p \right)^{1/p} + 8C\varepsilon = 1 + 8C\varepsilon.$$

Thus $T : X \to \ell_p(\bigcup_{s=1}^{\infty} \pi_s)$ given by $f \mapsto (\int_D f(x) \, dx)_{D \in \bigcup_{s=1}^{\infty} \pi_s}$ is the desired embedding.

The proof in the case that $(f_i)_{i=1}^{\infty}$ is a bounded fundamental minimal system for $X \subseteq L_p(\mathbb{R})$ is nearly identical. We let $K = \sup_i \|g_i\|_q$ and in the construction
replace (2.2)–(2.4) by

(2.2) For all $n_k < n \leq m \leq \tilde{m}$ and $f = \sum_{i=n}^{m} a_i f_i \in S_X$, 
\[ \left\| \sum_{i=n}^{m} a_i f_i |_{I_{k-1}} \right\|_p \leq \varepsilon 2^{-k} \text{ (using (**))}. \]

(2.3) For all $f = \sum_{i=1}^{n_k} a_i f_i$ with $|a_i| \leq K$ for $i \leq n_k$, 
\[ \| f \|_p \leq \varepsilon 2^{-k}. \]

(2.4) For all $f = \sum_{i=1}^{n_{k+1}} a_i f_i$ with $|a_i| \leq K$ for $i \leq n_{k+1}$, 
\[ \left\| f |_{A_k} - \sum_{D \in \Pi_k} \frac{X_D}{m(D)} \int_{D} f(x) \, dx \right\|_p \leq \varepsilon 2^{-k}. \]

The proof then proceeds as in the frame case for $f \in \text{span}(f_i)$, $f = \sum_{i=1}^{\ell} a_i f_i$, 
$\| f \|_p = 1$. \qed

Remark 2.5. Let $X \subseteq L_p(\mathbb{R})$ be as in Theorem 2.3 with $1 < p < \infty$. Then there is
a shorter proof that yields $X \hookrightarrow \ell_p$. In fact in the bounded minimal system case,
one can replace (**) by the weaker

(***) For all $\varepsilon > 0$ and bounded intervals $I \subseteq \mathbb{R}$, there exists $n \in \mathbb{N}$ so that if $f \in \text{span}(f_i)_{i \geq n}$ with $\| f \|_p = 1$, then $\| f |_{I} \|_p < \varepsilon$.

Indeed by [KP, H] and [JO], it suffices to prove that if $(x_n)$ is a normalized weakly null sequence in $X$, then some subsequence is 2-equivalent to the unit vector basis of $\ell_p$. Then, from (*) or (***) it is easy to find $(x_n)$ and intervals $I_1 \subseteq I_2 \subseteq \cdots$ so that $\| x_n |_{I_i \setminus I_{i-1}} \|_p > 1 - \frac{\varepsilon}{2}$ for all $i$ and deduce the result.

We will say that a frame $(f_i, g_i)_{i=1}^{\infty}$ for $X$ satisfies a lower $\ell_q$-estimate if for some $K < \infty$ and all $x \in X$,
\[ \left( \sum_{i=1}^{\infty} |g_i(x)|^q \right)^{1/q} \leq K \left\| \sum_{i=1}^{\infty} g_i(x) f_i \right\| = K \| x \| . \]
A Hilbert frame, by definition, satisfies lower (and upper) $\ell_2$-estimates.

If $(x_i)_{i=1}^{\infty}$ is a fundamental bounded minimal system for $X$, we say that $(x_i)_{i=1}^{\infty}$ satisfies a lower $\ell_q$-estimate if for some $K$ and all scalars $(a_i)_{i=1}^{n}$
\[ \left( \sum_{i=1}^{n} |a_i|^q \right)^{1/q} \leq K \left\| \sum_{i=1}^{n} a_i x_i \right\| . \]

Proposition 2.6. Let $1 < p < \infty$, $1/p + 1/q = 1$.

a) Assume $1 < p \leq 2$, and let $(f_i)_{i=1}^{\infty}$ be a sequence of uniformly discrete translations of $f \in L_p(\mathbb{R})$. Let either $(f_i, g_i)_{i=1}^{\infty} \subseteq L_p(\mathbb{R}) \times L_q(\mathbb{R})$ be a frame or $(f_i)_{i=1}^{\infty}$ be a fundamental bounded minimal system for $X \subseteq L_p(\mathbb{R})$. If $(f_i)_{i=1}^{\infty}$ admits a lower $\ell_q$-estimate, then $X$ embeds almost isometrically into $\ell_p$.

b) Let $(f_i, g_i)_{i=1}^{\infty}$ be a frame for $L_p(\mathbb{R})$, where $(f_i)_{i=1}^{\infty}$ is a sequence of uniformly discrete translations of $f \in L_p(\mathbb{R})$. Then for all bounded measurable sets $B$ of positive measure, $\sum_{i=1}^{\infty} \| g_i |_B \|_q^q = \infty$. 

License or copyright restrictions may apply to redistribution; see http://www.ams.org/journal-terms-of-use
Remark 2.7. The hypothesis in a) would be vacuous for \( p > 2 \) since some subsequence of \((f_i)\) is equivalent to the unit vector basis of \( \ell_p \).

Proof. First let \((f_i, g_i)_{i=1}^\infty\) be a frame for \( X \subseteq L_p(\mathbb{R}) \) as in a). Assume for all \( f \in X \),

\[
\left( \sum_{i=1}^\infty |g_i(f)|^q \right)^{1/q} \leq K \|f\|_p .
\]

For any bounded interval \( I \subseteq \mathbb{R}, f \in X \) and \( n \in \mathbb{N}, \)

\[
\left\| \sum_{i=n}^\infty g_i(f) f_i \right\|_p \leq \sum_{i=n}^\infty |g_i(f)| \left\| f_i \right\|_p
\]

\[
\leq \left( \sum_{i=n}^\infty |g_i(f)|^q \right)^{1/q} \left( \sum_{i=n}^\infty \left\| f_i \right\|_p^p \right)^{1/p}
\]

\[
\leq K \|f\|_p \left( \sum_{i=n}^\infty \left\| f_i \right\|_p^p \right)^{1/p} .
\]

From Proposition 2.1 we obtain that \((*)\) holds and so Theorem 2.3 applies.

Similarly, if \((f_i)\) is a fundamental bounded minimal system for \( X \) and \( f = \sum_i a_i f_i \) with \( \|f\|_p = 1 \), we have

\[
\left\| \sum_{i=1}^m a_i f_i \right\|_p \leq K \left( \sum_{i=1}^m \left\| f_i \right\|_p \right)^{1/p},
\]

and so, again, we have \((**\) and apply Theorem 2.3.

b) Assume that for some \( B \) of positive measure \( \sum_{i=1}^\infty |g_i|_B |^q < \infty \). Let \( h \in L_\infty(B), |h| = 1 \). So \( h = \sum_{i=1}^\infty (h, g_i) f_i |_B, \) the series converging in \( L_1(B) \). Thus

\[
m(B) = \|h\|_1 \leq \sum_{i=1}^n \left| (h, g_i) \right| \left\| f_i \right\|_1 + \sum_{i=n+1}^\infty \left| (h, g_i) \right| \left\| f_i \right\|_B
\]

\[
\leq \sum_{i=1}^n \left| (h, g_i) \right| \left\| f_i \right\|_1 + \left( \sum_{i=n+1}^\infty \left\| g_i \right\|_B^q \right)^{1/q} \left( \sum_{i=n+1}^\infty \left\| f_i \right\|_B^p \right)^{1/p} .
\]

Then, as in the proof of Proposition 2.2, we can choose \( n \) so that the second term does not exceed \( m(B)/4 \), and given this \( n \), choose \( h \) to make the first term also less than \( m(B)/4 \). Thus \( m(B) < \frac{1}{2} m(B) \), a contradiction. \( \square \)

Part a) of Proposition 2.6 yields a quantitative improvement of Theorem 1.6. If \( \{f(\lambda) : \lambda \in \Lambda\} \) is unconditional basic in \( L_2(\mathbb{R}) \), then given \( \varepsilon > 0 \) there is a partition \( \Pi \) of \( \mathbb{R} \) so that for all \( g \in X_2(f, \Lambda) \),

\[
\|g - E_\Pi g\|_2 \leq \varepsilon \|g\|_2 .
\]

Remark 2.8. a) Let \( f = \chi_{[0,1]} - \chi_{[1,2]} \in L_p(\mathbb{R}) \). The sequence \((f(n))_{n \in \mathbb{Z}} \) is basic in \( L_1(\mathbb{R}) \) when ordered as \((f(0), f(1), f(-1), f(2), f(-2), \ldots)\). It is unconditionally since in any \( L_p(\mathbb{R}) \)

\[
\left\| \sum_{i=-2n}^{2n} f(i) \right\|_p = 2 \left( \frac{1}{2} \right) \quad \text{but} \quad \left\| \sum_{i=-n}^{n} f(2i) \right\|_p = (2n + 2)^{1/p} .
\]
For $1 < p < \infty$, $(f_{(n)})_{n \in \mathbb{Z}}$ is neither a frame nor a minimal system in $L_p(\mathbb{R})$. The latter follows easily from the fact that

$$\lim_{n \to \infty} \left\| f_{(0)} + \sum_{k=1}^{n} \frac{n-k}{n} (f_{(k)} + f_{(-k)}) \right\|_p = 0.$$  

b) (Due to S.J. Dilworth.) Let $1 \leq p < \infty$, and let

$$f = \chi_{[-3/2,-1/2]} + 2\chi_{[-1/2,1/2]} + \chi_{[1/2,3/2]}.$$  

For $n \in \mathbb{N}$, set

$$g_n = f + \sum_{k=1}^{n} (-1)^n \frac{n-k+1}{n} (f_{(k)} + f_{(-k)}).$$  

Then for $x \geq 0$,

$$g_n(x) = \begin{cases} 
-f_{(-1)}(x) + f_{(0)}(x) - f_{(1)}(x) = -1 + 2 - 1 = 0 & \text{if } x \in [0, \frac{1}{2}], \\
(n-1)^k n - k + 1 \frac{k+1}{n} f_{(k)}(x) + (-1)^{k+1} n - k \frac{n-k-1}{n} f_{(k+1)}(x) + (-1)^{k+2} n - k \frac{n-k-1}{n} f_{(k+2)}(x) = 0 & \text{if } x \in [k+1, k+\frac{3}{2}] \\
(n-1)^{n-1} n - k \frac{n-k}{n} f_{(n-1)}(x) + (-1)^{n-1} n \frac{n-k}{n} f_{(n)}(x) = 0 & \text{if } x \in [n-\frac{1}{2}, n+\frac{1}{2}], \\
(-1)^n n \frac{n-k}{n} f_{(n)}(x) = (-1)^n n \frac{n-k}{n} & \text{if } x \in [n+\frac{1}{2}, n+\frac{3}{2}]. 
\end{cases}$$

Thus $\|g_n\|_p = 4^{1/p}/n$, hence $f_{(0)} \in \{\{f_{(k)} : k \in \mathbb{Z} \setminus \{0\}\} \}$ and so $(f_{(k)})_{k \in \mathbb{Z}}$ is not a minimal system in $L_p(\mathbb{R})$. Furthermore,

$$\hat{\chi}_{[-1/2,1/2]}(x) = \frac{1}{\sqrt{2\pi}} \int_{-1/2}^{1/2} e^{-ixt} dt = \frac{1}{\sqrt{2\pi}} \sin x \frac{x}{x}.$$  

It follows that

$$\hat{f}(x) = \frac{1}{\sqrt{2\pi}} \sin x \left[ 2 + \cos x \right],$$

so $\hat{f}(x) \neq 0$ a.e.

c) (Due to D. Freeman.) It is well known that if $(f_i)_{i=1}^{\infty}$ is a normalized sequence in $L_1(\mathbb{R})$ with $\|f_i\|_1 \geq \lambda > \frac{1}{2}$ for all $i$ and some sequence of pairwise disjoint measurable sets $I_i \subseteq \mathbb{R}$, then $(f_i)_{i=1}^{\infty}$ is equivalent to the unit vector basis of $\ell_1$. Indeed

$$\|\sum a_i f_i\|_1 \geq \sum |a_i f_i|_{I_i} - \sum |a_i| \sum |f_i|_{\mathbb{R} \setminus I_i} \geq \lambda \sum |a_i| - (1 - \lambda) \sum |a_i| = (2 \lambda - 1) \sum |a_i|.$$  

Thus if $\{f_{(\lambda)} : \lambda \in \Lambda\}$ is a sequence of uniformly discrete translations of $0 \neq f \in L_1(\mathbb{R})$, then it can be split into a finite number of subsequences, each equivalent to the unit vector basis of $\ell_1$.

d) By Theorem [1.1], if $1 \leq p < \infty$ and $f \in L_p(\mathbb{R})$, $f \neq 0$, then $\{f_{(\lambda)} : \lambda \in \mathbb{R}\}$ is linearly independent (see also Theorem [1.2] below). However, one can find $f \in L_1(\mathbb{R})$ so that $\{f_{(n)} : n \in \mathbb{Z}\}$ is not $\omega$-linearly independent in its natural order $\mathbb{R}$.
We next turn to the case where \((f_i)\) is unconditional basic in \(L_p\). We first recall

**Proposition 2.9** ([JO, Lemma 2]). Let \(1 \leq p \leq 2\). Let \((f_i) \subseteq L_p(\mathbb{R})\) be semi-normalized and unconditional basic. Assume that for some \(\delta > 0\) there exists a sequence of disjoint measurable sets \((B_i)_{i=1}^\infty\) with \(\|f_i\|_{L_p(B_i)} \geq \delta\), for all \(i\). Then \((f_i)_{i=1}^\infty\) is equivalent to the unit vector basis of \(\ell_p\).

**Corollary 2.10.** Let \((f_i)_{i=1}^\infty\) be an unconditional basic sequence in \(L_p(\mathbb{R})\), \(1 \leq p \leq 2\). Assume the \(f_i\)'s are all translates of some fixed \(f \in L_p(\mathbb{R})\). Then \((f_i)_{i=1}^\infty\) is equivalent to the unit vector basis of \(\ell_p\).

**Proof.** Let \(f_i = f(\lambda_i)\) for \(i \in \mathbb{N}\). Let \(\rho \equiv \frac{1}{2} \inf \{|\lambda_i - \lambda_j| : i \neq j\} > 0\). Let \(I\) be an interval of length \(\rho\) with \(\|f_i\|_p = \delta > 0\). If \(B_i = I + \lambda_i\), for \(i \in \mathbb{N}\), then the \(B_i\)'s are pairwise disjoint and \(\|f_i\|_p = \|f\|_p = \delta\), for all \(i\). Proposition 2.9 yields the result. \(\square\)

As we shall see, the situation is more complicated for \(p > 2\), and it is especially so for \(p > 4\).

**Theorem 2.11.** Let \(2 < p \leq 4\), and let \((f_i) \subseteq L_p(\mathbb{R})\) be an unconditional basic for \(X \subseteq L_p(\mathbb{R})\). Assume the \(f_i\)'s are all translates of some fixed \(f \in L_p(\mathbb{R})\). Then \(X\) embeds isomorphically into \(\ell_p\).

**Lemma 2.12.** Let \(p \neq 2\), and let \(X\) be a subspace of \(L_p(\mathbb{R})\) not containing an isomorph of \(\ell_p\). Then there exists \(c > 0\) so that \(\|f\| = \|f\|_{[-c,c]}\) is an equivalent norm on \(X\).

**Proof.** If the lemma is false, then we can find \((f_k)_{k=1}^\infty\) in \(S_X\) and \((m_k)_{k=1}^\infty \subseteq \mathbb{N}\) so that \(\|f_k\|_{[-m_k,m_k]} \geq 1 - 2^{-2k-1}\) and \(\|f_{k+1}\|_{[-m_k,m_k]} \leq 2^{-2k-1}\) for all \(k \in \mathbb{N}\). It follows easily that \((f_k)_{k=1}^\infty\) is equivalent to \((f_k)_{k=1}^\infty\) which, being semi-normalized and disjointly supported, is equivalent to the unit vector basis of \(\ell_p\). \(\square\)

We shall also use

**Proposition 2.13** ([JO]). Let \(X\) be a subspace of \(L_p(\mathbb{R})\), \(2 < p < \infty\), which does not contain an isomorph of \(\ell_2\). Then \(X\) embeds isomorphically into \(\ell_p\).

In fact by [KW], \(X\) must then embed almost isometrically into \(\ell_p\).

We set some notation and recall some things before proving the theorem. We let \((h_i)\) denote the normalized Haar basis for \(L_p[0,1]\) regarded, canonically, as a subspace of \(L_p(\mathbb{R})\). As mentioned in the introduction, for \(i \in \mathbb{N}\) and \(n \in \mathbb{Z}\), we let \(h_i(n) = h_i(n)\). Thus, \((h_i(n))_{i\in\mathbb{N}, n\in\mathbb{Z}}\) is an unconditional basis for \(L_p(\mathbb{R})\).

G. Schechtman [S] made the very useful observation that if \((f_i)_{i=1}^\infty\) and \((g_i)_{i=1}^\infty\) are semi-normalized unconditional basic sequences in \(L_p(\mathbb{R})\), \(1 < p < \infty\), with

\[
\sum_{i=1}^\infty \|f_i - g_i\|_p < \infty,
\]

then \((f_i)_{i=1}^\infty\) is equivalent to \((g_i)_{i=1}^\infty\). This follows from (1.3). In particular, if \((f_i)_{i=1}^\infty\) is semi-normalized unconditional basic in \(L_p(\mathbb{R})\), then, by first approximating each \((f_i)_{i=1}^\infty\) by a simple dyadic function and then using the above consequence of (1.3), there exists a block basis \((g_i)_{i=1}^\infty\) of \((h_i(n))_{i\in\mathbb{N}, n\in\mathbb{Z}}\) satisfying (2.8) and thus being equivalent to \((f_i)_{i=1}^\infty\).
Thus we need only show that \((2.10)\)

\[ \sum_{i=1}^{\infty} \|g_i|_l\|^p < \infty \quad \text{for all bounded intervals } I. \]

By (2.9) there exists \(M \in \mathbb{N}\) and \((2.11)\), and we maintain that this is false, then there exists a normalized block basis \((\bar{g}_i)_{i=1}^{\infty}\) of \((g_i)_{i=1}^{\infty}\) which is equivalent to the unit vector basis of \(\ell_2\). Set \(X = [\bar{g}_i]_{i=1}^{\infty}\). By Lemma \((2.12)\) there exists \(M \in \mathbb{N}\) and \(1 \leq C < \infty\) so that for all \(\bar{g} \in X, I = [-M, M]\),

\[ \|\bar{g}|_l\|_p \geq C^{-1}\|\bar{g}\|_p. \]

By (2.9) there exists \(n_0 \in \mathbb{N}\)

\[ \left( \sum_{i=n_0}^{\infty} \|g_i|_l\|^p \right)^{1/p} < (2C)^{-1}D^{-2}. \]

Let \(\bar{g}\) be an element of \(SX\) which has the property that if we expand it in terms of the \(g_i\)'s, i.e., if we write it as \(\bar{g} = \sum_{i=1}^{\infty} a_i g_i\), then \(a_j = 0\) for \(j \leq n_0\). From (2.10) and (2.11),

\[ C^{-1} \leq \|\bar{g}|_l\|_p \leq D \left( \sum_{i=n_0}^{\infty} a_i^2 \|g_i|_l\|^2 \right)^{1/2} \]

\[ \leq D \left[ \|(a_i^2)_{i=n_0}^{\infty}\|_{p/2} \cdot \|\|g_i|_l\|^2\|_{p/2} \|g_i|_l\|_{p/2} \right]^{1/2} \]

(declaring Hölder’s inequality for \(p/2\) and \(p/p - 2\))

\[ = D \|(a_i)_{i=n_0}^{\infty}\|_{p} \left( \sum_{i=n_0}^{\infty} \|g_i|_l\|^p \right)^{\frac{p-2}{p}} \]

\[ \leq D^2 \|\bar{g}|_l\|_p \left( \sum_{i=n_0}^{\infty} \|g_i|_l\|^p \right)^{1/p} \]
(by (2.11) and since \( p \leq 4, \frac{2p}{p-2} \geq p \))
\[
\leq (2C)^{-1} \quad \text{by (2.12)},
\]
which is a contradiction. \( \square \)

When \( p > 4 \) the possible structure is more complicated.

**Theorem 2.14.** Let \( 4 < p < \infty \). There exists \( f \in L_p(\mathbb{R}) \) and \( \Lambda \subseteq \mathbb{Z} \) so that \((f(\lambda))_{\lambda \in \Lambda}\) is an unconditional basic sequence with \( X_p(f, \Lambda) \) containing an isomorph of \( L_p(\mathbb{R}) \).

**Proof.** We identify, in the canonical way, \( L_p(\mathbb{R}) \) with \((\bigoplus_{t \in \mathbb{Z}} L_p([0,1]))_{t_p}\). Since \( L_p([0,1]) \) is isometrically isomorphic to \( L_p([0,1]^2) \), we need only produce \( f = (f_i)_{i \in \mathbb{Z}} \in \bigoplus_{t \in \mathbb{Z}} L_p([0,1]^2)_{t_p} \) and \( \Lambda \subseteq \mathbb{N} \) so that setting for \( \lambda \in \Lambda \) \( f(\lambda) = (f_{i-\lambda})_{i \in \mathbb{Z}} \), then \( X_p(f, \Lambda) \) contains an isomorph of \( L_p([0,1]) \) and \((f(\lambda))_{\lambda \in \Lambda}\) is unconditional.

Letting, as before, \((h_n)_{n=1}^\infty\) be the normalized Haar basis for \( L_p([0,1]) \) and \((r_n)_{n=1}^\infty\) the Rademacher functions on \([0,1]\), we have, for some constants \( C_p \) and \( D_p \) (see (1.3)) for all \((a_i) \subseteq \mathbb{R}\)
\[
(2.13) \quad \left( \sum_{i=1}^{\infty} |a_i|^2 \right)^{1/2} \leq \left\| \sum_{i=1}^{\infty} a_i r_i \right\|_p \leq C_p \left( \sum_{i=1}^{\infty} |a_i|^2 \right)^{1/2}
\]
and
\[
(2.14) \quad \left\| \sum_{i=1}^{\infty} a_i h_i \right\|_p \overset{D_p}{\sim} \left\| \sum_{i=1}^{\infty} a_i^2 |h_i|^2 \right\|_{p/2}^{1/2}.
\]

Since \( p > 4 \), we can choose \((\varepsilon_i)_{i=1}^\infty \subseteq (0,1)\) so that
\[
(2.15) \quad \sum_{i=1}^{\infty} \varepsilon_i^p = 1,
\]
and there exists a partition \((J_n)_{n=1}^\infty\) of \( \mathbb{N} \) into finite intervals with
\[
(2.16) \quad \sum_{j \in J_n} \varepsilon_j^4 = 1 \quad \text{for all} \quad n \in \mathbb{N}.
\]

We are ready to define \( f = (f_i)_{i \in \mathbb{Z}} \in \bigoplus_{t \in \mathbb{Z}} L_p([0,1]^2)_{t_p} \). Set for \( i \in \mathbb{Z}, \)
\[
(2.17) \quad f_i = \begin{cases} \varepsilon_j h_n \otimes r_j, & \text{if } i = 3^j \text{ with } j \in J_n \text{ for some } n \in \mathbb{N}, \\ 0, & \text{otherwise}, \end{cases}
\]
where \( h_n \otimes r_j \) is placed on the \( i \)th copy of \([0,1]^2\). Note that
\[
\|f\|_p^p = \sum_{n \in \mathbb{N}} \sum_{j \in J_n} \|\varepsilon_j h_n \otimes r_j\|_p^p = \sum_{n \in \mathbb{N}} \sum_{j \in J_n} \varepsilon_j^p = 1.
\]
Let \( \Lambda = \{-3^j : j \in \mathbb{N}\} \), and so our translated sequence is \((f_{-3^j})_{j=1}^\infty\). For ease of notation below we shall write \( f_{-3^j} \), \( f \) shifted \( 3^j \) units left, as \( f(-3^j) \), and \( f(-3^j) = (f_{-3^j})_{i \in \mathbb{Z}} \), where \( f_{-3^j} \) denotes \( f(-3^j) \) restricted to the \( i \)th \([0,1]^2\).
Now $f^{(-3^j)}_0 = \varepsilon_j h_n \otimes r_j$, if $j \in J_n$ and so for $(a_j) \subseteq \mathbb{R}$,

$$
\left\| \sum_{j \in \mathbb{N}} a_j f^{(-3^j)}_0 \right\|_p = \left\| \sum_{n \in \mathbb{N}} \sum_{j \in J_n} a_j \varepsilon_j h_n \otimes r_j \right\|_p
$$

$$
= \int_0^1 \int_0^1 \left| \sum_{n \in \mathbb{N}} \sum_{j \in J_n} a_j \varepsilon_j h_n(r_j(s)r_j(t)) \right|^p dt \, ds
$$

(2.18)

$$
C_p \int_0^1 \left| \sum_{n \in \mathbb{N}} \sum_{j \in J_n} a_j^2 \varepsilon_j^2 h_n^2(s) \right|^{p/2} ds , \text{ by (2.13)}
$$

$$
= \left\| \sum_{n \in \mathbb{N}} \left( \sum_{j \in J_n} a_j^2 \varepsilon_j^2 \right) h_n^2 \right\|^{p/2}
$$

$$
D_p \approx \left\| \sum_{n \in \mathbb{N}} \left( \sum_{j \in J_n} a_j^2 \varepsilon_j^2 \right)^{1/2} h_n \right\|^p, \text{ by (2.14)}
$$

Now for $j \in \mathbb{N}$, $f^{(-3^j)}_0 \neq 0$, iff $\ell = 3^k - 3^j$ for some $k \in \mathbb{N}$. If $\ell \neq 0$ and $\ell = 3^k - 3^j = 3^k - 3^{j'}$ for $k, k', j, j' \in \mathbb{N}$, then $k = k'$ and $j = j'$. Thus the functions $(f^{(-3^j)})_{j \in \mathbb{N}}$ are disjointly supported except on the 0th copy of $[0, 1]^2$.

Also

$$
\left\| \sum_{\ell \neq 0, \ell \in \mathbb{Z}} f^{(-3^j)}_0 \right\|_p = 1 - \varepsilon_j^p.
$$

From this and (2.18) we obtain for some $K$, for all $(a_i) \subseteq \mathbb{R}$,

$$
\left\| \sum_{j \in \mathbb{N}} a_j f^{(-3^j)}_0 \right\|_p \leq K \left\| \sum_{n \in \mathbb{N}} \left( \sum_{j \in J_n} a_j^2 \varepsilon_j^2 \right)^{1/2} h_n \right\|^p + \sum_{j \in \mathbb{N}} |a_j|^p.
$$

(2.19)

Thus $(f^{(-3^j)})_{j=1}^\infty$ is unconditional and we shall next construct a block basis $(b^{(n)})_{n=1}^\infty$ of $(f^{(-3^j)})_{j=1}^\infty$ which is equivalent to $(h_n)_{n=1}^\infty$.

For $n \in \mathbb{N}$, set

$$
b^{(n)}(n) = \sum_{j \in J_n} \varepsilon_j f^{(-3^j)}.
$$

From (2.19), for $(c_n) \subseteq \mathbb{R}$

$$
\left\| \sum_{n=1}^\infty c_n b^{(n)} \right\|_p = \left\| \sum_{n=1}^\infty c_n \sum_{j \in J_n} \varepsilon_j f^{(-3^j)} \right\|_p
$$

$$
\approx K_p \left\| \sum_{n=1}^\infty c_n \left( \sum_{j \in J_n} \varepsilon_j^4 \right)^{1/2} h_n \right\|^p + \sum_{n=1}^\infty \sum_{j \in J_n} |c_n| \varepsilon_j^p
$$

$$
= \left\| \sum_{n=1}^\infty c_n h_n \right\|^p + \sum_{n=1}^\infty |c_n|^p \left( \sum_{j \in J_n} \varepsilon_j^p \right).
$$

Thus, using this and (1.2), the lower $\ell_p$-estimate of $(h_n)_{n=1}^\infty$, we see that $(b^{(n)})_{n=1}^\infty$ is equivalent to $(h_n)_{n=1}^\infty$.

\[\square\]
We next note that under certain additional assumptions, we cannot have the situation of Theorem 2.14.

**Proposition 2.15.** Let $4 < p < \infty$, and let $(f_i)_{i=1}^{\infty}$ be an unconditional basis for $X \subseteq L_p(\mathbb{R})$ where the $f_i$’s are all translations of some fixed $f \in L_p(\mathbb{R})$. If either

a) $f \in L_2(\mathbb{R})$ or

b) $\sum_{n \in \mathbb{Z}} \|f|_{n-1, n}\|_{p}^{2p} < \infty$,

then $X$ embeds isomorphically into $\ell_p$.

**Proof.** b) follows easily from the proof of Theorem 2.11. Indeed we can use b) to deduce the next to last inequality in that proof rather than using a) as was done there.

a) We assume the contrary, so by Proposition 2.14, $X$ contains an isomorph of $\ell_2$. We choose $I$, $(g_i)_{i=1}^{\infty}$ and $(\bar{g}_i)_{i=1}^{\infty}$ as in the proof of Theorem 2.11 with the additional assumption that $\sum_{i=1}^{\infty} \| |f_i| - |g_i| \|_2 < \infty$.

Hence, using $f \in L_2(\mathbb{R})$,

\[ \sum_{i=1}^{\infty} \|g_i|_I\|_2^2 < \infty. \]  

(2.20)

Now $(\bar{g}_i|_I)_{i=1}^{\infty}$ is a block basis of $(h_{i,n})$ which is equivalent to the unit vector basis of $\ell_2$. This forces $\| \cdot \|_p$ and $\| \cdot \|_2$ to be equivalent on $[(\bar{g}_i|_I)_{i=1}^{\infty}] \subseteq L_p(I)$.

Since $(\bar{g}_i|_I)_{i=1}^{\infty}$ is also a normalized block basis of $(g_i)_{i=1}^{\infty}$, and so we may write $\bar{g}_i = \sum_{j=n_{i-1}+1}^{n_i} c_j g_j$ for some scalars $(c_j)$, $n_0 < n_1 < \cdots$ and all $i \in \mathbb{N}$. Since $(\bar{g}_i|_I)_{i=1}^{\infty}$ is also a block basis of $(h_{i,n})$ and hence is orthogonal in $L_2(I)$, we have for $i \in \mathbb{N}$,

\[ \| \bar{g}_i|_I\|_2 = \left\| \sum_{j=n_{i-1}+1}^{n_i} c_j g_j \right\|_2 = \left( \sum_{j=n_{i-1}+1}^{n_i} c_j^2 \|g_j|_I\|_2^2 \right)^{1/2}, \]

and the latter converges to 0 as $i \to \infty$ by (2.20). Thus $\| \bar{g}_i|_I\|_2 \to 0$ so $\| \bar{g}_i|_I\|_p \to 0$ which is a contradiction. \hfill \Box

We next present two more examples. The first is an easy example of a translation sequence in $L_p$ ($2 < p$) which is unconditional but not equivalent to the $\ell_p$-basis and so Theorem 2.11 cannot be improved to get $(f_i)$ equivalent to the unit vector basis of $\ell_p$. The second is a translation sequence $(f_i)$ in $L_p$, $p > 4$, which is basic but not unconditional.

**Example 2.16.** Let $2 < p < \infty$. There exists $f \in L_p(\mathbb{R})$ so that $(f(n_n))_{n=1}^{\infty}$, the sequence of translations of $f$ by $n \in \mathbb{N}$, is unconditional basis but not equivalent to the unit vector basis of $\ell_p$.

Of course we already know this for $p > 4$ by Theorem 2.11. Let $(r_n)_{n \in \mathbb{Z}}$ be an enumeration of the Rademacher functions on $[0, 1]$ extended trivially to functions defined on all of $\mathbb{R}$. We define $\tilde{r}_n(\cdot) = r_n(\cdot - n)$, for $n \in \mathbb{Z}$, and let $f = \sum_{n \in \mathbb{Z}} \frac{r_n}{\sqrt{|n|}}$,

where we regard $\frac{1}{\sqrt{|0|}} = 1$. Note that $\|f\|_p^p = 1 + 2 \sum_{n=1}^{\infty} n^{-p/2} < \infty$, since $p > 2$. 

Thus, for some $c_p > 0$

$$\|g\|_p^p = \sum_{k \in \mathbb{Z}} \|g|_{|k,k+1|}\|_p^p \gtrsim \sum_{k \in \mathbb{Z}} \left( \sum_{i=1}^{\infty} \left( \frac{a_i^2}{|k-i|} \right) \right)^{p/2},$$

which shows that $(f_{(i)})_{i=1}^\infty$ is unconditional. Moreover, if we let $a_i = 1$, for $i = 1, \ldots, m \in \mathbb{N}$ for $m \in \mathbb{N}$, we obtain

$$\left\| \sum_{i=1}^m f_{(i)} \right\|_p \geq c_p \sum_{k=1}^m \left( \sum_{i=1}^m \frac{1}{|m-i|} \right)^{p/2} \geq c_p m (\log m)^{p/2}.$$ 

Thus $(f_{(i)})$ is not equivalent to the unit vector basis of $\ell_p$. \hfill \Box

**Example 2.17.** Let $p > 4$. There exists $f \in L_p(\mathbb{R})$ and $\Lambda \subset \mathbb{Z}$ so that $\{f(\lambda) : \lambda \in \Lambda\}$ is basic in some order, but not unconditional.

As in Theorem 2.14 we identify $L_p(\mathbb{R})$ with $(\bigoplus_{n \in \mathbb{Z}} L_p[0,1])_p$, and we write $f$ as $(f_i)_{i \in \mathbb{Z}}$ with $f_i \in L_p(0,1)$, for $i \in \mathbb{Z}$, and, as in Theorem 2.14, we write $f(\lambda)$ instead of $f_{(\lambda)}$.

For $j \in \mathbb{N}$, let $a_j = j^{-1/4}$ and $a_0 = 1$. Let $(r_j)$ be the Rademacher sequence on $[0,1]$. We define $f = (f_i)_{i \in \mathbb{Z}}$ by

$$f_i = \begin{cases} a_{j-1}r_j - a_{j+1}r_{j+1}, & \text{if } i = 3^j \text{ for some } j \in \mathbb{N}, \\ 0, & \text{otherwise.} \end{cases}$$

Since $p > 4$, $(a_j) \in \ell_p$ and, thus, $f \in (\bigoplus_{n \in \mathbb{Z}} L_p[0,1])_p$. We let $\Lambda = \{-3^j : j \in \mathbb{N}\}$. For $(b_j)_{j=1}^n \subset \mathbb{R}$ we compute ($b_0 = 0$)

$$\sum_{j=1}^n b_j f_0^{(-3^j)} = \sum_{j=1}^n b_j f_{3^j}$$

$$= \sum_{j=1}^n b_j (a_{j-1}r_j - a_{j+1}r_{j+1})$$

$$= \sum_{j=1}^n (b_j a_{j-1} - b_{j-1}a_j)r_j - b_n a_{n+1}r_{n+1}.$$ 

We deduce that

$$\left\| \sum_{j=1}^n a_j f_0^{(-3^j)} \right\|_p = \|r_1 - a_n a_{n+1} r_{n+1}\|_p \to 1 \text{ if } n \to \infty, \text{ and}$$

$$\left\| \sum_{j=1}^n (-1)^{i+1} a_j f_0^{(-3^j)} \right\|_p = \|r_1 + \sum_{i=2}^n (-1)^{i+1} 2a_{i-1}a_i r_i \pm a_n a_{n+1} r_{n+1}\|_p$$

$$\sim \left( \sum_{i=1}^n a_i^4 \right)^{1/2} \left( \sum_{i=1}^n 1 \right)^{1/2}.$$
We can now apply the same arguments as in the proof of Theorem 2.14 and obtain
\[ \left\| \sum_j b_j f^{(-j^2)} \right\|_p \sim \left\| \sum_j b_j f_0^{(-j^2)} \right\|_p \wedge \left( \sum_j |b_j|^p \right)^{1/p}. \]
From this expression it follows that \( (f^{(-j^2)})_{j=1}^\infty \) is basic.
Indeed
\[ \left\| \sum_{j=1}^n b_j f^{(-j^2)} \right\|_p \sim \left( \sum_{j=1}^n (b_j a_{j-1} - b_{j-1} a_j)^2 + (b_n a_{n+1})^2 \right)^{1/2} \wedge \left( \sum_{j=1}^n |b_j|^p \right)^{1/p}. \]
Let the right hand expression be equal to 1 with
\[ \sum_{j=1}^n (b_j a_{j-1} - b_{j-1} a_j)^2 + (b_n a_{n+1})^2 = 1. \]
Then if \( (b_n a_{n+1})^2 \leq 1/2 \), for any extension \( (b_i)_{i=1}^m, m > n \), the right hand expression is at least \( 1/\sqrt{2} \). If \( (b_n a_{n+1})^2 \geq 1/2 \), then \( b_n > 1/2^{1/4} \), and so \( \left( \sum_{j=1}^n |b_j|^p \right)^{1/p} \geq 2^{-1/4} \).
Finally \( (f^{(-j^2)})_{j=1}^\infty \) is not unconditional since
\[ \left\| \sum_{j=1}^n a_j f^{(-j^2)} \right\|_p \sim (\log n)^{1/p} \]
while
\[ \left\| \sum_{j=1}^n (-1)^{j+1} a_j f^{(-j^2)} \right\|_p \sim (\log n)^{1/2}. \]
\[ \square \]

The translation problem can, of course, be considered in other rearrangement invariant function spaces on \( \mathbb{R} \). We end this section with a simple result in the space \( L_p(\mathbb{R}) \cap L_2(\mathbb{R}) \) for \( 2 < p < \infty \). The norm is given by \( \|f\| = \|f\|_p \vee \|f\|_2 \) and the space is isomorphic to \( L_p(\mathbb{R}) \) (see, e.g., [JMST] for more on this space).

**Proposition 2.18.** Let \( 2 < p < \infty \) and let \( (f_i)_{i=1}^\infty \) be an unconditional basis for \( X \subseteq L_p(\mathbb{R}) \cap L_2(\mathbb{R}) \) consisting of translations of some fixed \( f \in L_p(\mathbb{R}) \cap L_2(\mathbb{R}) \). Then \( (f_i)_{i=1}^\infty \) is equivalent to the unit vector basis of \( \ell_2 \).

**Proof.** As before, by first carefully approximating in both \( \| \cdot \|_p \) and \( \| \cdot \|_2 \) each \( f_i \) by a simple dyadic function \( f_i \) and then choosing a block basis \( (g_i)_{i=1}^\infty \) of \( (h_{i,n}) \) with \( |g_i| = |f_i| \) for all \( i \), we obtain that \( (g_i)_{i=1}^\infty \) is equivalent to \( (f_i)_{i=1}^\infty \) in \( L_p(\mathbb{R}) \cap L_2(\mathbb{R}) \).
Now \( (g_i)_{i=1}^\infty \) is unconditional and semi-normalized in \( L_p(\mathbb{R}) \cap L_2(\mathbb{R}) \) which is isomorphic to \( L_p \). Hence by (1.2), \( (g_i) \) admits an upper \( \ell_2 \)-estimate. Furthermore \( (g_i)_{i=1}^\infty \) is unconditional and semi-normalized in \( L_2(\mathbb{R}) \) and thus also admits a lower \( \ell_2 \)-estimate in \( \| \cdot \|_2 \) and so in \( L_p(\mathbb{R}) \cap L_2(\mathbb{R}) \). \[ \square \]

3. Discrete versions of the problem

It remains open if \( L_p(\mathbb{R}) \), \( 1 < p < \infty \), admits a basis of translations of some fixed \( f \in L_p(\mathbb{R}) \) (see section 4 for more open problems). The examples in section 3 were all integer translations and this leads to a natural

**Question 3.1.** Let \( 1 < p < \infty \). Is there a set \( \Lambda = \{ \lambda_n : n \in \mathbb{N} \} \subseteq \mathbb{Z} \) and an \( f \in L_p(\mathbb{R}) \) so that that \( (f(\lambda_n) : n \in \mathbb{N}) \) is a basis for \( L_p(\mathbb{R}) \)?
Proposition 3.2. Let $1 < p < \infty$. There is no $\lambda > 0$, and $f \in L_p(\mathbb{R})$ so that $\{f(\lambda n) : n \in \mathbb{Z}\}$ can be ordered to be a basis for $L_p(\mathbb{R})$.

Proof. We will prove a more general result below (see Proposition 3.7 and Corollary 3.12).

We can do a bit better in $L_1$ for certain spaces $X_1(f, (\lambda n)_{n \in \mathbb{Z}})$. By Theorem 1.1, $X_1(f, \mathbb{R}) = L_1(\mathbb{R})$ forces $\hat{f}(t) \neq 0$ for all $t$.

Lemma 3.3. Let $f \in L_1(\mathbb{R})$ with $\hat{f}(t) \neq 0$ for all $t$, and let $\Lambda = \{\lambda_n : n \in \mathbb{N}\}$ be uniformly discrete. Then $\{f(\lambda_n)\}_{n \in \mathbb{N}}$ is a non-fundamental minimal system in $L_1(\mathbb{R})$.

Proof. We use the fact that for a uniformly discrete $\Lambda$, there exists $a > 0$ so that $(e^{i\lambda_n t})_{n \in \mathbb{N}}$ is not complete in $C[-a,a]$. As pointed out to us by J. Bruna, this follows from the Paley-Wiener theory by constructing, from an entire function of finite exponential type, a Paley-Wiener function which vanishes on $\Lambda$. Alternately, this can also be quickly deduced from the Beurling-Malliavin radius of completeness formula (cf. Theorem 8, p. 129) and the fact that the uniformly discrete sequences have finite Beurling-Malliavin density. For convenience of the reader, we present a proof. We recall the definition of Beurling-Malliavin density $D_{BM}$. For $\Lambda \subset (0,\infty)$ and $D > 0$, a family of disjoint intervals $(a_k, b_k), 0 < a_1 < b_1 < \cdots < a_k < b_k < \cdots \rightarrow \infty$ is called substantial for $D$ if

$$n_A(a_k, b_k) > D, \quad k = 1, 2, \ldots, \sum_k \frac{b_k - a_k}{b_k} = \infty,$$

where $n_A(a_k, b_k)$ is the number points of $\Lambda$ in the interval $(a_k, b_k)$. Then the density is defined by

$$D_{BM}(\Lambda) = \sup\{D > 0 : \text{there exists a substantial family for } D\}.$$

For a general $\Lambda$, put $D_{BM}(\Lambda) = \max\{D_{BM}(\Lambda^+), D_{BM}(\Lambda^-)\}$ where $\Lambda^+ = \Lambda \cap \mathbb{R}^+$, $\Lambda^- = (-\Lambda) \cap \mathbb{R}^+$. The Beurling-Malliavin radius of completeness theorem asserts that $\{e^{i\lambda_n t} : \lambda_n \in \Lambda\}$ is complete in $C[-a,a]$ if and only if $\pi D_{BM}(\Lambda) \geq a$.

Now suppose that $\Lambda$ is uniformly discrete, and let $\delta = \inf\{\|\lambda - \lambda'\| : \lambda, \lambda' \in \Lambda, \lambda \neq \lambda'\} > 0$. Since $n_A(a_k, b_k)/(b_k - a_k) < 2/\delta$ for all $b_k > a_k > 0$, no $D > 2/\delta$ can be substantial for $\Lambda$, and therefore $D_{BM}(\Lambda) \leq 2/\delta$. Thus, by the Beurling-Malliavin theorem, $(e^{i\lambda_n t})_{n \in \mathbb{N}}$ is not complete in $C[-b,b]$ for $b > 2/\delta$.

To see the minimality of $\{f(\lambda_n)\}$, suppose to the contrary that for some $n_0$, $f_{\lambda_{n_0}} \in \{f_{\lambda_n} : n \neq n_0\}$ in $L_1(\mathbb{R})$. Then $\hat{f}_{\lambda_{n_0}}(t) = \hat{f}(t)e^{-i\lambda_{n_0} t} \in \{(\hat{f}(t)e^{-i\lambda_n t})_{n \neq n_0}\}$ in $C_0(\mathbb{R})$. Now $\hat{f}(t) \neq 0$ for all $t$, so $e^{-i\lambda_{n_0} t} \in \{e^{-i\lambda_n t} : n \neq n_0\} \subset C[-b,b]$ for all $b > 0$. Thus $(e^{-i\lambda_n t})_{n \neq n_0}$ is complete in $C[-b,b]$ (cf. Lemma 8, p. 129). This contradicts the fact when $b > a$. Similarly, observe that $\{f(\lambda_n)\}$ cannot be fundamental in $L_1(\mathbb{R})$, indeed otherwise $(e^{-i\lambda_n t})_{n \in \mathbb{N}}$ would be complete in $C[-b,b]$ for all $b > 0$.

Note that the assumption $\hat{f}(t) \neq 0$ for all $t$ is not frivolous due to Remark 2.3.
Let \( \ell \) generalize Proposition 3.5 in that case.

Proof. By Corollary 2.4 it suffices to show that \((f_{(\lambda n)})_{n\in\mathbb{Z}}\) is a bounded minimal system. By Lemma 3.3 it is a minimal system. Let \( g(f) = 1, g(f_{(\lambda n)}) = 0 \) for \( n \in \mathbb{Z} \setminus \{0\}, g \in L_\infty(\mathbb{R}) \). Then \((f_{(\lambda n)}, g_{(\lambda n)})_{n\in\mathbb{Z}}\) is a bounded minimal system. \(\square\)

Proposition 3.5 generalizes to \( \ell_p \)-sums of a separable infinite dimensional Banach space \( X \). Define \( \ell_p(X) = \ell_p(\mathbb{Z}, X) = (\bigoplus_{n\in\mathbb{Z}} X)_{\ell_p} \). For \( F = (f_n : n \in \mathbb{Z}) \in \ell_p(X) \) and \( k \in \mathbb{Z} \), let \( F^{(k)} \) be \( F \) shifted right \( k \) times. Precisely, \( F^{(k)} = (f_{n-k})_{n\in\mathbb{Z}} \).

**Proposition 3.5.** Let \( X \) be a separable infinite dimensional Banach space, \( 1 \leq p < \infty \). There does not exist \( F \in \ell_p(\mathbb{Z}, X) \) so that \( \{F^{(k)} : k \in \mathbb{Z}\} \) is a basis for \( \ell_p(\mathbb{Z}, X) \) in some order.

Proof. Let \( 1/p + 1/q = 1 \), and assume for some \( F \) that \( \{F^{(n_i)}\}_{i=1}^{\infty} \) is a basis for \( \ell_p(\mathbb{Z}, X) \) where \( (n_i)_{i=1}^{\infty} \) is a reordering of \( \mathbb{Z} \). Let \( (G_i)_{i\in\mathbb{N}} \subseteq \ell_q(\mathbb{Z}, X^*) \) be the biorthogonal functionals to \( \{F^{(n_i)}\}_{i=1}^{\infty} \). Choose \( i_0 \) with \( n_i = 0 \), and set \( G_{i_0} = G = (g_n)_{n\in\mathbb{Z}}, g_n \in X^* \) for \( n \in \mathbb{N} \).

For \( n, m \in \mathbb{N} \),

\[
\langle F^{(n)}, G^{(m)} \rangle = \sum_{k\in\mathbb{Z}} \langle f_k - n, g_k - m \rangle = \sum_{k\in\mathbb{Z}} \langle f_k + m - n, g_k \rangle = \langle F^{(n-m)}, G_{i_0} \rangle = \delta_{(m,n)}.
\]

Again, from the uniqueness of the biorthogonal functionals to a basis (for \( \ell_p(\mathbb{Z}, X) \)), we see that \( G_i = G^{(n_i)} \) for all \( i \in \mathbb{N} \).

Choose \( j \in \mathbb{N} \) with

\[
\left( \sum_{i=j+1}^{\infty} \|f_{-n_i}\|^p \right)^{1/p} \leq \frac{1}{2\|G\|}.
\]

Since \( X \) is infinite dimensional, there exists \( x \in S_X \) with \( g_{-n_i}(x) = 0 \) for all \( i \leq j \). Set \( H = (\delta_{(0,n)} x : n \in \mathbb{Z}) \in \ell_p(\mathbb{Z}, X) \). Then

\[
H = \sum_{i=1}^{\infty} \langle H, G^{(n_i)} \rangle F^{(n_i)} = \sum_{i=j+1}^{\infty} \langle H, G^{(n_i)} \rangle F^{(n_i)}.
\]

Hence,

\[
1 = \|x\| = \|H\| = \left\| \sum_{i=j+1}^{\infty} \langle H, G^{(n_i)} \rangle F^{(n_i)} \right\| = \sum_{i=j+1}^{\infty} \langle g_{-n_i}, f_{-n_i} \rangle
\]

\[
\leq \sum_{i=j+1}^{\infty} \|g_{-n_i}\| \|f_{-n_i}\| \leq \|G\| \left( \sum_{i=j+1}^{\infty} \|f_{-n_i}\|^p \right)^{1/p} \leq \frac{1}{2},
\]

a contradiction. \(\square\)

**Problem 3.6.** Let \( 2 < p < \infty \), and let \( X \) be a Banach space with \( \dim X \geq 2 \). Does there exist \( F \in \ell_p(\mathbb{Z}, X) \) and \( (\lambda_i : i \in \mathbb{N}) \subseteq \mathbb{Z} \) so that \( \{F^{(\lambda_i)}\}_{i=1}^{\infty} \) is a basis for \( \ell_p(\mathbb{Z}, X) \)? What if \( \dim X = 2 \) or if \( X = \ell_p \)?

We do not ask the question for \( p \leq 2 \) because of the following proposition which generalizes Proposition 3.5 in that case.
Proposition 3.7. Let \(1 \leq p \leq 2\), and let \(X\) be a Banach space with \(\dim(X) \geq 2\). Let \(F = (f_i : i \in \mathbb{Z}) \in \ell_p(\mathbb{Z}, X)\). Then \([\{F(n) : n \in \mathbb{Z}\}] \neq \ell_p(\mathbb{Z}, X)\).

Corollary 3.8 ([AO]). Let \(1 < p \leq 2\), \(f \in L_p(\mathbb{R})\), and \(\lambda > 0\). Then \([f(\lambda n) : n \in \mathbb{Z}]\) is a proper subspace of \(L_p(\mathbb{R})\). In particular, no subsequence of \([f(n) : n \in \mathbb{Z}]\) can be ordered to form a basis for \(L_p(\mathbb{R})\).

Proof. We let \(F\) denote the Fourier transform on \(L_1(\mathbb{R}) + L_2(\mathbb{R})\) into the space of measurable functions on \(\mathbb{R}\). \(F\) is a bounded linear operator, restricted to \(L_1(\mathbb{R})\) (into \(C_0(\mathbb{R})\)) and when restricted to \(L_2(\mathbb{R})\) (into \(L_2(\mathbb{R})\)). By the Riesz-Thorin interpolation theorem, \(F\) is also bounded as a linear operator from \(L_p(\mathbb{R})\) into \(L_q(\mathbb{R})\) \((1/p + 1/q = 1\). Now since \(L_1(\mathbb{R}) \cap L_2(\mathbb{R}) \subseteq L_p(\mathbb{R})\), \(F(L_p(\mathbb{R}))\) is dense in \(L_q(\mathbb{R})\). For \(f \in L_p(\mathbb{R})\) and \(s \in \mathbb{R}\), we have \(F(f_s) = e^{-ist}F(f)\). Indeed for \(f \in L_1(\mathbb{R})\) and \(t \in \mathbb{R}\),

\[
F(f_s)(t) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{ixt} f(x-s) \, dx = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^{\infty} e^{-i(ut+s)t} f(u) \, du = e^{-is}F(f)(t) .
\]

For a general \(f \in L_p(\mathbb{R})\) the result follows by the standard density argument.

Let \(f \in L_p(\mathbb{R})\) and \(\lambda \in \mathbb{R}\). If \([\{f(\lambda n) : n \in \mathbb{Z}\}] = L_p(\mathbb{R})\), then \([\{e^{i\lambda n\zeta}F(f) : n \in \mathbb{Z}\}] = L_q(\mathbb{R})\). This implies that \(F(f) \neq 0\) a.e., and that \([\{e^{i\lambda n\zeta} : n \in \mathbb{Z}\}] = L_q(|F(f)|^q \, dx)\). This in turn implies that all elements \(g\) of \(L_q(|F(f)|^q \, dx)\) are \(\lambda\)-periodic \((g(x) - g(x + \lambda) = 0\) a.e.), a contradiction. \(\square\)

Remark 3.9. For \(2 < p < \infty\), it is shown in [AO] (Theorem 1.2 above) that there exists \(f \in L_p(\mathbb{R})\) so that \([\{f^{(n)} : n \in \mathbb{Z}\}] = L_p(\mathbb{R})\).

We will use the Fourier transform on the abelian group \(\mathbb{Z}\) (see [Ru]) and also assume our spaces to be defined over the complex field. For \(x = (\zeta_j) \in \ell_1(\mathbb{Z})\), we let \(\hat{x}\) be the function

\[
\hat{x} : [-\pi, \pi] \to \mathbb{R}, \quad \hat{x}(t) = \sum_{n \in \mathbb{Z}} \zeta_n e^{int} .
\]

It is easy to see that \(\hat{x} \in C(T)\) when \(x \in \ell_1(\mathbb{Z})\) (identifying, as usual, the torus \(T\) with \([-\pi, \pi]\) by identifying \(\pi\) and \(-\pi\)). Also the map

\[
(\cdot) : \ell_1(\mathbb{Z}) \to C(T), \quad x \mapsto \hat{x},
\]

is a bounded linear operator of norm 1. For any \(x = (\zeta_n : n \in \mathbb{Z})\),

\[
\|\hat{x}\|^2 = \int_{-\pi}^{\pi} \left| \sum_{n \in \mathbb{Z}} \zeta_n e^{int} \right|^2 dt = \int_{-\pi}^{\pi} \sum_{m,n \in \mathbb{Z}} \bar{\zeta}_m \zeta_n e^{i(n-m)t} \, dt = 2\pi \sum_{n \in \mathbb{Z}} |\zeta_n|^2 .
\]

Thus \((\cdot)\) extends to an isometry from \(\ell_2(\mathbb{Z})\) to \(L_2(T, \frac{1}{2\pi} \, dx)\).

Again, by the Riesz-Thorin interpolation theorem, the Fourier transform is a bounded linear operator from \(\ell_p(\mathbb{Z})\) into \(L_q(\mathbb{T})\) for \(1 \leq p \leq 2\), \(1/p + 1/q = 1\).

Since \([\{\hat{x} : x \in \ell_1(\mathbb{Z})\}]\) is dense in \(L_2(\mathbb{T})\), it follows that the image under the Fourier transform of \(\ell_p(\mathbb{Z})\) is dense in \(L_q(\mathbb{T})\).
We also need two lemmas before proving Proposition 3.7. The first is an easy exercise in real analysis.

**Lemma 3.10.** Let \( \nu \ll \mu \) be two \( \sigma \)-finite measures on the measure space \((\Omega, \Sigma)\). Then for \( 1 \leq p < \infty \), if \( D \subseteq L_p(\nu) \cap L_p(\mu) \) is dense in \( L_p(\mu) \), it is also dense in \( L_p(\nu) \).

**Proof.** Let \( \rho \) be the Radon-Nikodym density of \( \nu \) with respect to \( \mu \). For \( n \in \mathbb{N} \) set
\[
A_n = \{ \omega \in \Omega : \frac{1}{n} \leq \rho(\omega) \leq n \}.
\]
For \( n \in \mathbb{N} \), it follows that \( L_p(\mu|A_n) = L_p(\nu|A_n) \). Also by canonically identifying \( L_p(\nu|A_n) \) with a subspace of \( L_p(\nu) \), \( \bigcup_{n \in \mathbb{N}} L_p(\nu|A_n) \) is dense in \( L_p(\nu) \), and this yields the results. \( \Box \)

**Lemma 3.11.** Let \( 1 \leq p \leq 2 \), and let \( x = (\xi_n : n \in \mathbb{Z}) \in \ell_p(\mathbb{Z}) \). Then \([\{x^{(2n)}\}_{n \in \mathbb{Z}}] \neq \ell_p(\mathbb{Z})\).

**Proof.** Recall \( x^{(n)} = (\xi_{-n} : j \in \mathbb{Z}) \), for \( n \in \mathbb{Z} \). For \( n \in \mathbb{N}, t \in T \) and \( z = (\zeta_j : j \in \mathbb{Z}) \in \ell_1(\mathbb{Z}) \) we have
\[
\hat{z}^{(n)}(t) = \sum_{j \in \mathbb{Z}} \zeta_j e^{ijt} = \sum_{\ell \in \mathbb{Z}} \zeta_{\ell} e^{i(\ell+n)t} = e^{in\hat{z}}.
\]
By a density argument, we see that for any \( x \in \ell_p(\mathbb{Z}) \) and \( n \in \mathbb{Z}, x^{(n)} = e^{in\hat{x}} \).

Assume, to the contrary, that \([\{x^{(2n)}\}_{n \in \mathbb{Z}}] = \ell_p(\mathbb{Z})\). It then follows that \( \{e^{i2nt}\hat{x} : n \in \mathbb{Z}\} = L_q(T) \) and thus \( \hat{x} \neq 0 \) a.e. Also that \([\{e^{i2nt}\hat{x} : n \in \mathbb{Z}\}] = L_q(T, |\hat{x}|^q \, dt) \).

By Lemma 3.10 this implies that \([\{e^{i2nt}\hat{x} : n \in \mathbb{Z}\}] = L_q(T) \).

Since for any \( n \in \mathbb{Z}, \)
\[
2\pi \langle e^{i2nt}, \chi_{[-\pi,0]} - \chi_{[0,\pi]} \rangle = \int_{-\pi}^{0} e^{i2nt} \, dt - \int_{0}^{\pi} e^{i2nt} \, dt
= \int_{0}^{\pi} (e^{-i2nt} - e^{i2nt}) \, dt = \begin{cases} 0, & \text{if } n = 0, \\ -2 \int_{0}^{\pi} \sin(2nt) \, dt = 0, & \text{if } n \neq 0, \end{cases}
\]
this cannot be true. \( \Box \)

**Proof of Proposition 3.7.** After projecting \( X \) onto \( \ell^2_p \), we see that we may assume \( X = \ell^2_p \). Let \( I \) be the obvious isometry between \( \ell_p(\mathbb{Z}, X) \), and let \( \ell_p(\mathbb{Z}) \) be denoted \((x_j)_{j \in \mathbb{Z}} \mapsto (y_j)_{j \in \mathbb{Z}} \), where if \( x_j = (x_{j,1}, x_{j,2}) \in \ell^2_p \), then
\[
y_{2j} = x_{j,1}, \quad y_{2j+1} = x_{j,2}.
\]
Then for \((x_j)_{j \in \mathbb{Z}} \in \ell_p(\ell^2_p), (x^{(n)})_{n \in \mathbb{Z}} = (I(x)^{2n})_{n \in \mathbb{Z}} \) and the result follows from Lemma 3.11. \( \Box \)
Remark. As noted above by the results of [AO] in section 4 we cannot hope to prove that given $f \in L_p(\mathbb{R})$, $2 < p < \infty$, $[(f^{(n)})_{n\in\mathbb{Z}}] \neq L_p(\mathbb{R})$. Nevertheless, by dualizing Proposition 3.7, we have the following

**Corollary 3.12.** Let $X$ be a Banach space with $\dim(X) \geq 2$, and let $2 \leq p < \infty$. Let $F = (f_i)_{i\in\mathbb{Z}} \in \ell_p(\mathbb{Z}, X)$. Then $\{F^{(n)} : n \in \mathbb{Z}\}$ is not a basis for $\ell_p(\mathbb{Z}, X)$ under any ordering.

**Proof.** Assume that $F \in (f_i)_{i\in\mathbb{Z}} \in \ell_p(\mathbb{Z}, X)$ and that $(n_s)_{s\in\mathbb{N}}$ is an ordering of $\mathbb{Z}$ so that $(F^{(n_s)})_{s=1}^{\infty}$ is a basis for $\ell_p(\mathbb{Z}, X)$. Let $(G_s)_{s=1}^{\infty} \subseteq \ell_q(\mathbb{Z}, X^*)$ be the biorthogonal functionals of $(F^{(n_s)})_{s=1}^{\infty}$. Set $G = (g_j)_{j\in\mathbb{Z}} = G_1$. We let $G^{(m)} = (g_{j-m})_{j\in\mathbb{Z}}$, as usual. For $s, t \in \mathbb{N}$ and $m \in \mathbb{Z}$, we have

$$
\langle F^{(n_s)}, G^{(m)} \rangle = \sum_{j\in\mathbb{Z}} \langle f_{j-n_s}, g_{j-m} \rangle = \sum_{k\in\mathbb{Z}} \langle f_{k+n_s-n_s}, g_k \rangle = \langle F^{(n_s)}, G_1 \rangle = \begin{cases} 1 & \text{if } n_s - n_t = n_1, \\ 0 & \text{if } n_s - n_t \neq n_1. \end{cases}
$$

As before, we see that $G_s = G^{(n_s-n_1)}$. In particular, span$\{G^{(n)} : n \in \mathbb{Z}\}$ is $w^*$-dense in $\ell_q(X^*)$. Let $E$ be a two-dimensional subspace of $X$, and let $P$ be a projection of $X$ onto $E$. Let $Q : \ell_p(\mathbb{Z}, X) \to \ell_p(\mathbb{Z}, E)$ be the projection given by $Q(H) = (P(h_i))_{i\in\mathbb{Z}}$. It follows that span$\{G^{(n)}|_{\ell_p(\mathbb{Z}, E)} : n \in \mathbb{Z}\}$ is $w^*$-dense in $\ell_q(\mathbb{Z}, E^*)$ and hence norm dense (the latter is reflexive). This contradicts Proposition 3.7. □

### 4. Results from the literature and open problems

We first cite some more known results from the literature.

**Theorem 4.1 ([DH] Theorem 5.1(b)).** Let $g^{(1)}, g^{(2)}, \ldots, g^{(m)} \in L_2(\mathbb{R}^d) \cap L_1(\mathbb{R}^d)$, and let $\Gamma_1, \Gamma_2, \ldots, \Gamma_m \subset \mathbb{R}^d$ be countable. Then $\{g^{(i)}_{\lambda} : i = 1, 2, \ldots, m, \lambda \in \Gamma_i\}$ cannot be ordered to be a Schauder basis of $L_2(\mathbb{R}^d)$.

**Theorem 4.2 ([ER] and [RJ], cf. [H] Theorem 9.18]).** If $g \in L_p(\mathbb{R}^d)$, $g \neq 0$, and $1 \leq p \leq \frac{2d}{d-1}$, then the functions $\{g(\cdot) - \alpha_k : k = 1, 2, \ldots, N\}$ are linearly independent for any $N \in \mathbb{N}$ and any collection $(\alpha_k)_{k=1}^{N} \subseteq \mathbb{R}^d$ of distinct points.

If $\frac{2d}{d-1} < p \leq \infty$, then for $N \in \mathbb{N}$ there exists $0 \neq g \in L_p(\mathbb{R}^d)$ and distinct points $(\alpha_k)_{k=1}^{N} \subseteq \mathbb{R}^d$ so that $\{g(\cdot) - \alpha_k : k = 1, 2, \ldots, N\}$ is linearly dependent.

Our last cited result requires some notation. For $\Lambda \subseteq \mathbb{R}$, let $\mathcal{E}(\Lambda) = \text{span}\{e^{i\lambda(\cdot)} : \lambda \in \Lambda\}$. Let $R(\Lambda) = \sup\{\rho > 0 : \mathcal{E}(\Lambda) \text{ is dense in } C[-\rho, \rho]\}$. Recall, $\Lambda \subseteq \mathbb{R}$ is discrete if it has no accumulation points.

**Theorem 4.3 ([BOU] Theorem 1]).** Let $\Lambda \subseteq \mathbb{R}$ be discrete. There exists $f \in L_1(\mathbb{R})$ so that $\{f(\lambda) : \lambda \in \Lambda\} = L_1(\mathbb{R})$ if and only if $R(\Lambda) = \infty$.

Finally we list some problems that remain open. The main one is

**Problem 4.4.** Let $1 < p < \infty$. Does there exist $f \in L_p(\mathbb{R})$ and $\Lambda \subseteq \mathbb{R}$ so that $\{f(\lambda) : \lambda \in \Lambda\}$ can be ordered to be a basis for $L_p(\mathbb{R})$? Can we find $f$ and a uniformly discrete set $\Lambda$ so that $\{f(\lambda) : \lambda \in \Lambda\}$ can be ordered to be a frame for $L_p(\mathbb{R})$?
By identifying $L_p(\mathbb{R})$ with $L_p[0,1]$ we have a more general version of the basis problem in 4.4.

**Problem 4.5.** Does there exist a normalized basis $(f_n)_{n=1}^{\infty}$ for $L_p[0,1]$, $1 < p < \infty$, so that for all $0 < b < 1$,

$$
\sum_{n=1}^{\infty} \|f_n|_{[0,b]}\|^p < \infty ?
$$

If $4 < p < \infty$, can we find such $f_n$’s which form an unconditional basis for $L_p[0,1]$?

**Problem 4.6.** Let $4 < p < \infty$. Does there exist $f \in L_p(\mathbb{R})$ and $\Lambda \subseteq \mathbb{R}$ so that $(f(\lambda))_{\lambda \in \Lambda}$ is an unconditional basis for $L_p(\mathbb{R})$?

We can also raise questions asking for less, and here is one such question.

**Problem 4.7.** Let $1 < p < 4$. Does there exist $f \in L_p(\mathbb{R})$ and a uniformly discrete set $\Lambda \subseteq \mathbb{R}$ so that $\{f(\lambda) : \lambda \in \Lambda\} \subseteq L_p(\mathbb{R})$ contains an isomorph of $\ell_2$ and $(f(\lambda))_{\lambda \in \Lambda}$ can be ordered to be a basic sequence (or a frame)?

**Problem 4.8.** Let $\Lambda \subseteq \mathbb{R}$ be uniformly discrete and $f \in L_1(\mathbb{R})$. Does $X_1(f,\Lambda)$ embed into $\ell_1$?
