LIQUID DROPS SLIDING DOWN AN INCLINED PLANE

INWON KIM AND ANTOINE MELLET

Abstract. We investigate a one-dimensional model describing the motion of liquid drops sliding down an inclined plane (the so-called quasi-static approximation model). We prove existence and uniqueness of a solution and investigate its long-time behavior for both homogeneous and inhomogeneous media (i.e. constant and non-constant contact angle). We also obtain some homogenization results.

1. Introduction

1.1. Equilibrium drops and quasi-static approximation. Consider a liquid drop lying on an inclined plane. We introduce a coordinate system such that this plane is the \((x, y)\)-plane, and we assume that the free surface of the drop (the liquid/vapor interface) can be described as the graph of a function \(u(x, y)\). For small droplets, the energy of an equilibrium drop can be approximated by

\[
\mathcal{J}(u) = \sigma \int_{\mathbb{R}^2} \frac{1}{2} |\nabla u|^2 + \beta \chi_{\{u>0\}} \, dx \, dy + \int_{\mathbb{R}^2} \int_0^{u(x,y)} \Gamma \, dz \, dx \, dy,
\]

where \(\sigma\) denotes the surface tension coefficient and \(\beta(x, y)\) is the relative adhesion coefficient between the fluid and the solid. If the support plane is inclined at an angle \(\alpha\) to the horizontal in the \(x\)-direction, the gravitational potential \(\Gamma\) can be written as

\[
\Gamma = \rho g (z \cos \alpha - x \sin \alpha)
\]

and the Euler-Lagrange equation for the minimization of \(\mathcal{J}\) with volume constraint is the following equation (known as the Young-Laplace equation):

\[
\begin{aligned}
-\Delta u &= \lambda - u \kappa \cos \alpha + x \kappa \sin \alpha & \text{in } \{u>0\} \\
\frac{1}{2} |\nabla u|^2 &= \beta & \text{on } \partial \{u>0\},
\end{aligned}
\]

with \(\kappa = \rho g / \sigma\) and where \(\lambda\) is a Lagrange multiplier associated with the volume constraint. Note that the Dirichlet integral \(\int |\nabla u|^2 \, dx \, dy\) is an approximation of the surface tension energy, which classically involves the perimeter \(\int \sqrt{1 + |\nabla u|^2} \, dx \, dy\) (see [3]). This perimeter functional leads to a mean curvature operator which would be much more delicate to deal with than the Laplace operator appearing in [3].

It is well known (see [3]) that when \(\beta\) is constant and \(\kappa > 0\), then [3] has no solution (this can be seen by multiplying the first equation in [3] by \(u_x\) and...
integrating over \( \{ u > 0 \} \) - it is also obvious that any translation of \( u \) down the
\( x \)-axis will decrease the energy \( J \).

This means that on a perfectly homogeneous surface, any drop should slide down
the inclined plane, no matter how small the inclination of the plane \( \alpha \). This is not
the case when \( \beta \) is a function of \( x \). In that case, one expects some drops to stick
to the inclined plane, at least for small inclination (or small volume). This sticking
phenomenon was rigorously investigated by Caffarelli-Mellet [2] when \( \beta \) is assumed
to be periodic with period \( \varepsilon \ll 1 \).

In any case, large drops will always eventually slide down the inclined plane, and
it is the purpose of this paper to investigate the motion of such drops when \( \beta \) is
constant (homogeneous surface) and when it is not (heterogeneous surface). There
are a number of papers (see for instance [1,5,8] and the references therein) in
the fluid dynamics literature discussing the behavior of sliding drops. Interesting
phenomena are observed. In particular, the shape of the drop can change drastically
when the velocity is increased, and a singularity (corner) develops at the rear of
the drop when the velocity exceeds a certain critical value (and a cusp may form
at an even higher velocity).

In this paper, we aim at studying such phenomena in the framework of a (rel-
atively) simple model for the motion of liquid drops usually referred to as the
quasi-static approximation. We will see that this model does allow for singularity
formation of the type discussed above.

1.2. The quasi-static approximation model. In the quasi-static approxima-
tion regime, the contact line is assumed to move slowly (compared to the speed
of capillary relaxation), so that at each instant there is a balance between gravita-
tional force and surface tension (see [5,8]). The free surface of the drop is thus at
equilibrium at all time and can be described by a function \( u(x,y,t) \) solution of

\[
-\Delta u = \lambda(t) - u \kappa \cos \alpha + x \kappa \sin \alpha \quad \text{in } \{ u(t) > 0 \},
\]

where the constant \( \lambda(t) \) is determined by the volume constraint

\[
\int u(x,t) \, dx = V_0.
\]

Along the free boundary (or contact line) \( \partial \{ u > 0 \} \), the equilibrium contact
angle condition is assumed to be satisfied only at some microscopic scale, and the
deviation of the “apparent” contact angle \( \theta = |\nabla u| \) from the equilibrium value
\( \theta_e = \sqrt{2\beta} \) is responsible for the motion of the contact line. The relation between
the velocity of the contact line and the contact angle \( \theta \) is not a settled issue, and
various velocity laws have been proposed (see [5, 8, 13]) and studied (see [4]).
Following Blake and Ruschak [1], we assume that the speed is proportional to
\( \theta^2 - \theta_e^2 \). More precisely, we assume that the normal velocity \( V \) of the contact line
\( \partial \{ u > 0 \} \) is given by

\[
V = \frac{1}{2} |\nabla u|^2 - \beta \quad \text{on } \partial \{ u > 0 \}.
\]

This particular velocity law has the advantage of leading to a gradient flow for-
mulation for (4)-(5). This gradient flow formulation will be discussed in the next
section, but let us already stress that [5] leads to an obvious problem when the
drop is sliding down: In the rear of the drop (where \( V < 0 \)), the speed \( |V| \) is
bounded by $\beta$, while in the front of the drop (where $V > 0$), the speed can increase without bounds (and is expected to increase if the volume of the drop or the inclination increase). This would lead to ever-increasing support of the drop, which is incompatible with (4) (indeed, we will see that (4) does not admit positive solutions on large domains). This problem can be fixed by noticing that (5) should not be expected to hold in the degenerate case where $\nabla u = 0$ along the free boundary. In the next section, we will see that the gradient flow formulation naturally leads to an obstacle problem type formulation of the velocity law of the form (see (10))

\begin{equation}
\min \left\{ -V + \frac{1}{2} |\nabla u|^2 - \beta, |\nabla u| \right\} = 0 \text{ on } \partial\{u > 0\}.
\end{equation}

The free boundary problem (4)-(6) has been studied by Grunewald and Kim [6] in the particular case $\alpha = 0$. In that case, we always have $|\nabla u| > 0$ along the free boundary, and so (5) holds (instead of (6)). In the present paper, we are interested in the case $\alpha > 0$, for which the degeneracy of $|\nabla u|$ cannot be ruled out. In that case, the existence of solutions (which is the main focus in [6]) is not the only interesting issue. Indeed, one would also like to know whether a given drop will stick or will slide down the plane. When it does slide down the plane, one would also like to characterize the motion of the drop. We will see that there exist some traveling wave type solutions which describe the asymptotic speed and profile of any sliding drops. Finally, one would like to determine the effects of heterogeneities of the inclined plane on the motion of the sliding drops. We refer to [10,11] for results concerning the motion of liquid droplets on a horizontal heterogenous plane (see also [12] for similar results in the framework of Hele-Shaw flow).

Such issues are rather delicate to investigate in full generality. In this paper, we develop the analysis of (4)-(6) (and answer all the above questions) in the one-dimensional case. In particular, we prove the existence and uniqueness of solutions (for general functions $\beta$) and we study their long-time behavior when $\beta$ is constant and when it is periodic. This one-dimensional model could be interpreted as modeling the motion of a fixed volume of fluid initially placed uniformly across the inclined plane (ridge of fluid). However, such a configuration is not usually stable (the leading edge may become unstable in the span-wise direction as it flows down the inclined plane). We thus prefer to think of this study as a starting point for a more general study involving the higher-dimensional case.

As we will see, even this (simpler) case already leads to interesting behavior. In particular, the profile of the drop may degenerate in the rear of the drop (touching the ground tangentially). Of course, in dimension two and higher, the dynamics of the drops is much more complex since topology changes seem unavoidable (splitting and merging of droplets).

Finally, let us mention that one of the main difficulties in studying this problem (regardless of the dimension) is the lack of comparison principle due to the volume constraint (no viscosity solutions), since $\lambda$ depends on $t$ in (4). Also, there is no way to get rid of this volume constraint, especially when addressing the long-time behavior of the drops. Indeed, if we were to fix $\lambda(t) = \lambda_0$ and solve (4)-(6), it is easy to check that in most cases the drop would simply vanish in finite time.

1.3. Gradient flow structure. As mentioned above, the system of equations (4)-(5) has a natural gradient flow structure which we will now explain. This is true
in any dimension, but our discussion will be restricted to one dimension here, both for simplicity and for consistency with our analysis in the rest of the paper.

For a given non-negative function \( v \in H^1(\mathbb{R}) \) with a compact support, we denote by

\[
\mathcal{F}(v) = \int_{\mathbb{R}} \frac{1}{2} |v_x|^2 + \frac{v^2}{2} \kappa \cos \alpha - v x \kappa \sin \alpha \ dx
\]

the energy of the corresponding drop, and for a given open interval \( I = (a,b) \subset \mathbb{R} \), we define

\[
(7) \quad u_I = \arg \min \{ \mathcal{F}(v) : v \in H^1_0((a,b)), v \geq 0, \int v = V_0 \}.
\]

When \( \alpha = 0 \), it is easy to show that the solution of (4) with support \([a,b]\) and volume \(V_0\) is non-negative in \((a,b)\). When \( \alpha > 0 \), this is not the case when \(b-a\) is large. As a consequence, we do not have \( \text{supp } u_I = [a,b] \) when \(b-a\) is large (see Proposition 3.5 (iv)). This is the main difference with the case \( \alpha = 0 \), and this is the reason why we need the additional obstacle condition \( v \geq 0 \) in (7).

We now define the energy of an open interval as

\[
\mathcal{E}(I) = \mathcal{F}(u_I) + \int_I \beta dx.
\]

Formally, (4)-(5) is the gradient flow for the energy \( \mathcal{E} \) over the set of open intervals with respect to the distance given by

\[
(8) \quad \text{dist}((a,b),(c,d)) = \left( \int |\chi_{(a,b)}(x) - \chi_{(c,d)}(x)|^2 dx \right)^{1/2}.
\]

Indeed, let us consider a solution \( I(t) = (a(t),b(t)) \) of the gradient flow

\[
\langle \partial_t I(t), v \rangle = -\text{diff } \mathcal{E}(I)(v),
\]

where \( v : \{a(t),b(t)\} \to \mathbb{R} \) is any velocity field applied to the endpoints of the interval \( I(t) \). Here \( \partial_t I(t) \) denotes the velocity field \( \tilde{V} := (a'(t),b'(t)) \), and we have

\[
\langle \partial_t I(t), v \rangle := b'(t)v(b(t)) - a'(t)v(a(t))
\]

and

\[
\text{diff } \mathcal{E}(I)(v) := \lim_{\tau \to 0^+} \frac{\mathcal{E}(I + \tau v) - \mathcal{E}(I)}{\tau}.
\]

We can then show that \( \tilde{V} \) satisfies \(5\) as long as \( I = \text{supp } u_I \). To see this, let \( \varepsilon \) be any velocity field applied to the endpoints of the interval \( I \) and let \( \delta u := \ldots \)
\( \frac{1}{\tau}(u_{I+\tau\tilde{v}} - u_I) \). Assuming that \( |(u_I)_x| \neq 0 \) on \( \partial I \), we get

\[
\text{diff } E(I)(\tilde{v}) = \lim_{\tau \to 0} \left( \int_I (u_I)_x (\delta u)' + (u_I\kappa \cos \alpha - x\kappa \sin \alpha) \delta u \, dx + \int_{\partial I} \left[ \beta + \frac{1}{2} |(u_I)_x|^2 \right] \tilde{v} \, dS \right)
\]

\[
[10pt] = \lim_{\tau \to 0} \left( \int_I \left[ - (u_I)_xx + u_I\kappa \cos \alpha - x\kappa \sin \alpha \right] \delta u \, dx + \int_{\partial I} \left[ - |(u_I)_x| \delta u + \left( \beta + \frac{1}{2} |(u_I)_x|^2 \right) \tilde{v} \right] \, dS \right)
\]

\[
[10pt] = \int_{\partial I} \left( \beta - \frac{1}{2} |(u_I)_x|^2 \right) \tilde{v} \, dS,
\]

where in the first equality we used the fact that \( u_I = 0 \) on \( \partial I \), and the third inequality is a consequence of the following expansion:

\[
\delta u = \tilde{v}|(u_I)_x| + o(\tilde{v}) \text{ on } \partial I.
\]

This implies

\[
\tilde{V} = \frac{1}{2} |(u_I)_x|^2 - \beta.
\]

However, as mentioned above, when \( \alpha > 0 \), the solution of (7) will have a support strictly smaller than \( I \) when \( I \) is large (because gravity is pushing \( u \) “downward”, in the direction of the increasing \( x \)). In that case, the obstacle free boundary condition yields \( |(u_I)_x| = 0 \) along \( \partial \{ u_I > 0 \} \setminus \partial I \) and we do not recover (5). If we denote by \( V \) the normal velocity of \( \text{supp } u_I \), it is clear that whenever \( \text{supp } u_I \neq I \), we have \( V \leq \tilde{V} \). Since this can only happen when \( |(u_I)_x| = 0 \), we obtain the following equation for the velocity \( V \):

\[
\min \left\{ -V + \frac{1}{2} |(u_I)_x|^2 - \beta, |(u_I)_x| \right\} = 0 \text{ on } \partial \{ u_I > 0 \}.
\]

One can rigorously show that the above heuristics are valid, using the discrete-time (JKO) scheme introduced in [6] (see also [9]): For a given initial open interval \( I^0 \) and time step size \( h > 0 \), let us consider the sequence of open intervals \( I^i_h \) with \( i = 1, 2, 3, \ldots \), iteratively defined by

\[
I^{i+1}_h := \arg \min \{ \text{open interval} \} \left\{ \frac{1}{h} \text{dist}^2 (I^i_h, I) + E(I) \right\}, \quad I^0_h = I^0,
\]

where \( \text{dist} \) is a modified version of the distance given in [8] (see [6] for a general formulation and references for higher dimensions):

\[
\text{dist}^2 ((a, b), (c, d)) = \int_{(a, c) \cup (b, d)} d(x, \{a, b\}) \, dx.
\]

Let \( u_h(\cdot, t) \) and \( \lambda_h(\cdot, t) \) be the associated function and Lagrange multiplier to \( I^{i+1}_h \) defined at discrete times \( t = ih \). Lastly, define

\[
u_h(\cdot, t), \lambda_h(\cdot, t) \equiv u_h(\cdot, ih), \lambda_h(\cdot, ih) \quad \text{for } t = ih \leq t < (i + 1)h.
\]
Following [6], we can then show:

**Proposition 1.1.** Let $u_h$ and $I_h$ be as given above.

(a) Suppose there exists a classical solution $\phi$ of
\[
\begin{aligned}
-\phi_{xx} &< \lambda_h(t) - \delta - \phi \kappa \cos \alpha + x \kappa \sin \alpha & \text{in } \{\phi > 0\}, \\
V &< \frac{1}{2} |\phi_x|^2 - \beta - \delta & \text{on } \partial \{\phi > 0\} \cap \{|D\phi| \neq 0\}.
\end{aligned}
\]
If $h$ is sufficiently small depending on $\delta$, then $\phi$ cannot cross $u_h$ from below.

(b) Suppose there exists a classical solution $\phi$ of
\[
\begin{aligned}
-\phi_{xx} &> \lambda_h(t) + \delta - \phi \kappa \cos \alpha + x \kappa \sin \alpha & \text{in } \{\phi > 0\}, \\
V &> \frac{1}{2} |\phi_x|^2 - \beta - \delta & \text{on } \partial \{\phi > 0\}.
\end{aligned}
\]
If $h$ is sufficiently small depending on $\delta$, then $\phi$ cannot cross $u_h$ from above.

The proof of Proposition 1.1 follows that of Proposition 3.1 and Proposition 3.3 in [6]. Note that from (11) it follows that $I_i h$ cannot move its endpoints by more than $C h$ from the endpoints of $I_i^{h-1}$, where $C$ depends on the energy associated with $I^0$. It follows that along a subsequence $u_h, \lambda_h$ and $I_h$ locally uniformly converge as $h \to 0$. Proposition 1.1 then ensures that the limiting solution satisfies (7) and that the motion law satisfies (10) in the viscosity sense.

This discrete-time scheme, which relies on the gradient-flow structure of our problem, can thus be used to prove the existence of solution. However, it is not a very practical scheme, especially in one dimension. For this reason we will use a different, simpler, discrete-time scheme to construct classical solutions of (7)-(10) (see Section 4.2).

In the next section, we will state all the results proved in this paper. The rest of the paper (Sections 3 to 7) will be devoted to the proof of these results.

### 2. main results and outline of the paper

Throughout the paper, the volume of the drop $V_0$ is fixed (we only compare drops with the same volume), and we assume that the drop is invariant in the $y$ direction. As discussed in the introduction, the sliding drop problem then reduces to finding a function $u(x, t)$ and a set $I(t) = \{u(t) > 0\}$ such that

\[
\begin{aligned}
\frac{\partial u(t)}{\partial t} &= \arg\min \{\mathcal{F}(v) \; ; \; v \in H^1_0(I(t)), \; v \geq 0, \; \int v \, dx = V_0\}, \\
\min \left\{ -V + \frac{1}{2} |u_x|^2 - \beta, \; |u_x| \right\} &= 0 \quad \text{on } \partial \{u > 0\},
\end{aligned}
\]

where $V$ denotes the normal velocity of $\partial I(t)$ and $\mathcal{F}$ is given by
\[
\mathcal{F}(v) = \int \frac{1}{2} |v_x|^2 + \frac{v^2}{2} \kappa \cos \alpha - v \kappa x \sin \alpha \, dx.
\]

We note that in one dimension there is no mechanism which would allow a connected drop to split into several droplets (we will show this rigorously in Section 4, when we construct a solution using a time-discretized scheme). We thus assume that the drop is connected at time $t = 0$, that is, $u_0(x)$ satisfies $\{u_0 > 0\} = (a_0, b_0)$ and

\[
u_0 = \arg\min \{\mathcal{F}(v) \; ; \; v \in H^1_0(a_0, b_0), \; v \geq 0, \; \int v \, dx = V_0\}.
\]
Our problem then reduces to finding $I(t) = (a(t), b(t))$ satisfying (13). This leads to the following definition:

**Definition 2.1.** Given an initial data $u_0$ satisfying (14), we say that $u(x,t)$ is a solution of (13) if there exist some Lipschitz functions $a(t)$ and $b(t)$ defined for $t \geq 0$, satisfying

$$a(0) = a_0, \quad b(0) = b_0$$

and such that

$$\{x; u(x,t) > 0\} = (a(t), b(t)) \quad \text{for all } t \geq 0,$$

(15)

$$u(\cdot,t) = \arg\min\{\mathcal{F}(v); v \in H^1_0(a(t), b(t)), v \geq 0, \int_{a(t)}^{b(t)} v(x) \, dx = V_0\} \text{ for all } t \geq 0,$$

(16)

and

$$\left\{ \begin{array}{l}
\min\{a'(t) + \frac{1}{2}|u_x(a(t))|^2 - \beta(a(t)), |u_x(a(t))|\} = 0 \\
\min\{-b'(t) + \frac{1}{2}|u_x(b(t))|^2 - \beta(b(t)), |u_x(b(t))|\} = 0
\end{array} \right. \quad \text{a.e. } t \geq 0.$$  

With this definition in hand, our first result is the following:

**Theorem 2.2.** Assume that $x \mapsto \beta(x)$ is a Lipschitz continuous function. For any $u_0$ satisfying (14), there exists a unique solution $u(x,t)$ in the sense of Definition 2.1.

Furthermore, we have the following “comparison principle”, which plays a crucial role in our analysis:

**Proposition 2.3** (Comparison principle and uniqueness). Assume that $x \mapsto \beta(x)$ is a Lipschitz function, and let $u_1, u_2$ be two solutions of (13) (in the sense of Definition 2.1) with support $(a_1(t), b_1(t)), (a_2(t), b_2(t))$ such that

$$a_1(0) \leq a_2(0) \quad \text{and} \quad b_1(0) \leq b_2(0).$$

(17)

Then

$$a_1(t) \leq a_2(t) \quad \text{and} \quad b_1(t) \leq b_2(t) \quad \text{for all } t > 0.$$  

(18)

Furthermore, if the inequalities are strict in (17), then they are also strict in (18).

We stress the fact that the solutions $u_1$ and $u_2$ correspond to drops with the same volume $V_0$ (the result would obviously not hold for two drops with a different volume). The result is not trivial because $u_1$ and $u_2$ do not satisfy the same equation (different Lagrange multipliers).

Next, we investigate the existence of particular solutions characterizing the asymptotic behavior of general solutions. We start with the case where $\beta$ is constant, and we show that there exists a unique traveling wave solution (for a given volume and up to translation in time), which is stable:

**Theorem 2.4.** When $\beta$ is constant, problem (13) has a traveling wave type solution of the form $u(x,t) = v(x - ct)$. The profile $v(x)$ is unique (up to translation), and the speed $c$ is given by

$$c = \left\{ \begin{array}{ll}
\frac{1}{2} V_0 \kappa \sin \alpha & \text{if } V_0 \leq 2 \frac{\beta}{\kappa \sin \alpha}, \\
V_0 \kappa \sin \alpha - \beta & \text{if } V_0 \geq 2 \frac{\beta}{\kappa \sin \alpha}.
\end{array} \right.$$

(19)
Finally, any solution $u(\cdot, t)$ of (13) converges uniformly in $x$ as $t \to \infty$ to a translation of this traveling wave $u$.

Note that $V_0 \kappa \sim L^2 \frac{\rho g}{\sigma} = B_0$ is the so-called Bond number ($L$ denotes the characteristic dimension of the drop). So (19) implies that the speed $c$ of the traveling wave is a piecewise linear function of $B_0 \sin \alpha$, which increases faster once the drop reaches a critical volume (we will see that this corresponds to the volume for which the receding contact angle - or the gradient in the rear of the drop - becomes degenerate).

This linear dependence is commonly observed in experiments (see [13, Figure 7] for instance). However, these same experiments also invariably show that drops stick to the plane for small inclination (or small volume) and only start sliding above a critical slope. This is typically seen as a consequence of contact angle hysteresis, which is due to the roughness (or chemical contamination) of the support. Such roughness can be taken into account in our model via the coefficient $\beta$.

In the last part of this paper, we thus consider the case of the non-constant coefficient $\beta$, and we investigate the effects of this roughness on the speed of the sliding drops. We will see (see Figure 2) that this has a strong effect on the velocity of small drops (or for small inclination) in a way that is consistent with experimental data (see [13]).

To simplify the analysis, we consider a simple case in which the constant $\beta$ is replaced by a periodic function $x \mapsto \beta(x)$.

Our first result says that stationary solutions do exist, for small volume (or small inclination), and that a small enough drop may stick to the inclined plane. Large volume drops, however, will slide down, and the notion of traveling wave solutions is replaced by that of pulsating traveling solutions (which are global in time solutions whose profile exhibits some periodic behavior). More precisely, we will show:

**Theorem 2.5.** Assume that $x \mapsto \beta(x)$ is a periodic function. Then the following hold:

(i) If

$$\max \beta - \min \beta < V_0 \kappa \sin \alpha,$$

then there exists a unique pulsating traveling solution $u(x, t)$ solution of (13) (that is, a global in time solution satisfying $u(x, t+T) = u(x+1, t)$ for all $t$). Furthermore, any solution will eventually start sliding with positive speed ($b'(t) > 0$ for $t \geq t_0$) and will converge to the unique pulsating traveling solution as $t \to \infty$.

(ii) If

$$\max \beta - \min \beta > V_0 \kappa \sin \alpha,$$

then there exists $\delta$ such that if the period of $\beta$ is less than $\delta$, any solution will stick to the inclined plane. More precisely, we have

$$a(t) \geq a(0) - C \quad \text{or} \quad b(t) \geq b(0) - C \quad \text{for all } t \geq 0.$$

Finally, our last result concerns the homogenization of the problem above. We now assume that $x \mapsto \beta_\varepsilon(x)$ is a $\varepsilon$-periodic function (for the sake of simplicity, we take $\beta_\varepsilon(x) = \beta(x/\varepsilon)$).
First, we state the following lemma which will be proved in the appendix:

**Lemma 2.6.** Assume that $x \mapsto \beta(x)$ is periodic. Then, for all $q \in \mathbb{R}$, the equation

$$x'(t) = q - \beta(x(t))$$

has a unique global solution (up to translation in time), which is periodic in time. We define by

$$r(q) := \lim_{t \to \infty} \frac{x(t) - x(0)}{t}$$

its effective speed. The function $q \mapsto r(q)$ is monotone increasing and continuous, and satisfies

$$r(q) = 0, \quad \text{for } q \in [\min \beta, \max \beta].$$

Note that the fact that $r(q)$ can be zero in a non-trivial interval is a classical and important aspect of the homogenization of contact angle dynamics (see Figure 1). It typically implies pinning of the contact line: for related results in higher dimensions, we refer to [10] and [11].

We can now state our homogenization result:

**Theorem 2.7.** Let $u^\varepsilon$ be a solution of (13) with initial value $u_0$ and where $\beta = \beta(x/\varepsilon)$ with $\beta$ a periodic function. When $\varepsilon$ goes to zero, $u^\varepsilon$ converges uniformly to a function $u(x,t)$ solution of (15)–(16) satisfying the following velocity law:

$$\begin{align*}
\min\{a'(t) + r\left(\frac{1}{2}|u_x(a(t))|^2, |u_x(a(t))|\right), |u_x(a(t))|\} &= 0 \\
\min\{-b'(t) + r\left(\frac{1}{2}|u_x(b(t))|^2, |u_x(b(t))|\right), |u_x(b(t))|\} &= 0 \\
&\quad \text{a.e. } t \geq 0.
\end{align*}$$

Furthermore, there is at most one solution $u$ of the homogenized problem (15)–(16), and (22) with given initial data $u_0$.

To conclude this analysis, we note that the homogenized problem described in Theorem 2.7 has traveling wave solutions for all volumes (for a small volume, the
traveling wave has speed zero, so it is really a stationary solution). The speed of that traveling wave can be determined as follows:

- If \( r(V_0 \kappa \sin \alpha) + r(0) < 0 \), then there exists \( q_0 \) such that
  \[
  r(q_0 + V_0 \kappa \sin \alpha) + r(q_0) = 0
  \]
  and the speed of the traveling wave solution is given by
  \[
  c = r(q_0 + V_0 \kappa \sin \alpha) = -r(q_0)
  \]
  (note that \( q_0 \) may not be unique, but \( c \) is unique).
- If \( r(V_0 \kappa \sin \alpha) + r(0) \geq 0 \), then the speed of the traveling wave solution is given by
  \[
  c = r(V_0 \kappa \sin \alpha)
  \]
  (when this happens, the gradient in the rear of the drop of the traveling wave solution is zero).

Of course, we recover the speed of the traveling wave for constant coefficient \( \beta \) (formula (19)) when we take \( r(q) = q - \beta \). Figure 2 compares the speed of the traveling wave as a function of \( V_0 \kappa \sin \alpha \) for the homogenized problem (22) when \( \beta_\epsilon(x) = 1 + 0.3 \sin(x/\epsilon) \) (solid line), and for the constant case \( \beta = \langle \beta_\epsilon \rangle = 1 \). Note the Lipschitz corner near \( V_0 \kappa \sin \alpha = 2 \) which corresponds to the critical volume for which the gradient in the rear of the drop becomes zero.

The rest of the paper is devoted to the proof of these results.

3. Preliminaries

3.1. Another formulation for (13). Definition 2.1 gives the most natural notion of a solution for (13). However, it is not the most practical one. In this section, we derive an equivalent formulation which will be more convenient. First, we note
that if \( u \) is a solution in the sense of Definition \ref{def:2.1}, then \( u(\cdot, t) \) solves:
\[
\begin{align*}
-u_{xx} &= \lambda(t) - u\kappa \cos \alpha + (x - b(t))\kappa \sin \alpha & \text{in} \ (a(t), b(t)), \\
ua(t, t) &= ub(t, t) = 0, \\
\int u \, dx &= V_0.
\end{align*}
\]

(23)

It is tempting to replace (15)-(16) by (23). However, solutions of (23) take negative values when the interval \((a(t), b(t))\) is too large (this will be a consequence of Proposition \ref{prop:3.5} below). We thus write:

**Definition 3.1.** Given an initial data \( u_0 \) satisfying (14), we say that \( u(x, t) \) is a solution of (13) if there exist some Lipschitz functions \( a(t) \) and \( b(t) \) satisfying
\[
a(0) = a_0, \quad b(0) = b_0
\]
such that \( u(\cdot, t) \) solves (23) for all \( t \geq 0 \) and \( a(t), b(t) \) satisfy
\[
\begin{align*}
\min\{a'(t) + \frac{1}{2}|u_x(a(t))|^2 - \beta(a(t)), u_x(a(t))\} &= 0, \\
b'(t) &= \frac{1}{2}|u_x(b(t))|^2 - \beta(b(t)).
\end{align*}
\]

(24)

In this second formulation, the positivity of \( u \) in \((a(t), b(t))\) is enforced by the condition \( u_x(a(t)) \geq 0 \). Indeed, we can show:

**Lemma 3.2.** Let \( u(\cdot, t) \) be the solution of (23); then \( -u_x(b(t), t) > 0 \). Furthermore, \( u(x, t) > 0 \) in \((a(t), b(t))\) if and only \( u_x(a(t), t) \geq 0 \). In particular, Definitions \ref{def:2.1} and \ref{def:3.1} are equivalent.

Note that it might have seemed more natural to write the second equation in (24) as
\[
\min\{-b'(t) + \frac{1}{2}|u_x(b(t))|^2 - \beta(b(t)), -u_x(b(t))\} = 0.
\]

However, Lemma \ref{lem:3.2} shows that the condition \( -u_x(b(t)) > 0 \) always holds.

**Proof of Lemma 3.2.** We drop the \( t \) dependence in what follows. Since \( V_0 > 0 \), there exists \( x_0 \in (a, b) \) such that \( u(x_0) = \max_{x \in (a, b)} u > 0 \). Since \( -u''(x_0) \geq 0 \), (23) implies
\[
\lambda + (x_0 - b)\kappa \sin \alpha \geq u(x_0)\kappa \cos \alpha > 0.
\]

(25)

Assume now that \( u \) has a local minimum at a point \( x_1 \in (a, b) \). Then \( -u''(x_1) \leq 0 \), and so (23) implies
\[
\lambda + (x_1 - b)\kappa \sin \alpha \leq u(x_1)\kappa \cos \alpha.
\]

Since \( u(x_1) \leq u(x_0) \), we deduce
\[
x_1 \leq x_0,
\]
and so we always have \( u(x) > 0 \) in \((x_0, b)\). In particular, we have \( -u'(b) \geq 0 \). In order to show that \( -u'(b) > 0 \), we note that (25) also implies \( \lambda > 0 \), and so the function \( h(x) = -\mu(x - b) \) satisfies
\[
-h'' \leq \lambda - h\kappa \cos \alpha + (x - b)\kappa \sin \alpha = \lambda - [\mu\kappa \cos \alpha + \kappa \sin \alpha](b - x)
\]
in a neighborhood of \( b \). A Hopf’s Lemma type argument yields \( -u'(b) > 0 \).

Assume now that \( u'(a) \geq 0 \) and that there exists \( x_0 \in (a, b) \) such that \( u(x_0) \leq 0 \). Using the boundary conditions, we deduce that there exist at least three distinct points in \([a, b]\) where \( u' \) vanishes, and so there exist at least two distinct points \( y_1 \), \( y_2 \) in \((a, b)\) where \( u'' \) vanishes.
Therefore, the function \( w = u \kappa \cos \alpha \) solves
\[
w'' = \kappa \cos \alpha w \quad \text{in} \ (a, b),
\]
is such that \( w''(y_i) = w(y_i) = 0 \), \( i = 1, 2 \), and the maximum principle implies \( w = 0 \) in \((y_1, y_2)\) and thus \( w = 0 \) in \((a, b)\), which is impossible (look at the values of \( w \) at \( a \) and \( b \)).

We have thus shown that \( u'(a) \geq 0 \) implies that \( u > 0 \) in \((a, b)\). Conversely, if \( u > 0 \) in \((a, b)\), it is readily seen that \( u'(a) \geq 0 \).

Finally, we give a third definition which will be very useful later on. We will show in Proposition 3.5 (iv) that there exists a critical length \( \ell_c > 0 \) (depending on the volume \( V_0 \) and the inclination \( \alpha \)) such that the solution of (23) is positive in \((a(t), b(t))\) if and only if \( b(t) - a(t) \leq \ell_c \). This length \( \ell_c \) is the longest possible length of the support of the drop. This leads to the following third formulation:

**Definition 3.3.** Given an initial data \( u_0 \) satisfying (14), we say that \( u(x, t) \) is a solution of (13) if there exist some Lipschitz functions \( a(t) \) and \( b(t) \) such that \( u(\cdot, t) \) solves (28) and
\[
a(0) = a_0, \quad b(0) = b_0
\]
with
\[
\begin{aligned}
\min \{ a'(t) + \frac{1}{2}|u_x(a(t))|^2 - \beta(a(t)), & a(t) - b(t) + \ell_c \} = 0 \\
b'(t) = \frac{1}{2}|u_x(b(t))|^2 - \beta(b(t)),
\end{aligned}
\]
a.e. \( t \geq 0 \).

Equivalently, denoting \( \ell(t) = b(t) - a(t) \), we can write:
\[
\begin{aligned}
\max \{ \ell'(t) - \left[ \frac{1}{2}|u_x(b(t))|^2 + \frac{1}{2}|u_x(a(t))|^2 - \beta(a(t)) - \beta(b(t)) \right], & \ell(t) - \ell_c \} = 0, \\
b'(t) = \frac{1}{2}|u_x(b(t))|^2 - \beta(b(t)),
\end{aligned}
\]
where \( u_x(b(t)) \) and \( u_x(a(t)) \) only depend on \( l(t) \) (see Proposition 3.5 (iii)). We then have:

**Proposition 3.4.** Definitions 3.1 and 3.3 are equivalent.

In order to prove this proposition, we will need to derive several important properties of the solution of the obstacle problem (16), which is done in the next section. Proposition 3.4 will be an immediate consequence of Proposition 3.8 below.

3.2. Analysis of the obstacle problem (16). Throughout this section, we fix a volume \( V_0 \), and all constants will depend on \( V_0, \alpha \) and \( \kappa \).

Given \( a < b \), we consider \( u \) a solution of
\[
u = \arg \min \{ F(v) ; v \in H^1_{\text{loc}}(a, b), \ v \geq 0, \ \int_a^b v(x) \, dx = V_0 \}.
\]
Then classical arguments for obstacle type problems (see e.g. [7]) yield that \( u \in C^{1,1}(a, b) \) solves
\[
\begin{aligned}
\min \{ -u'' - \lambda - (x - b)\kappa \sin \alpha + u\kappa \cos \alpha, u \} = 0 & \quad \text{in} \ (a, b), \\
u(a) = u(b) = 0, & \quad \int u \, dx = V_0
\end{aligned}
\]
(where \( \lambda \in \mathbb{R} \) is determined by the volume constraint).
The main properties of $u$ are gathered in the following proposition:

**Proposition 3.5.** Let $u$ be a $C^{1,1}$ solution of (29). Then:

(i) $\{u > 0\}$ is an interval of the forms $(a', b)$ and $-u'(b) > 0$.

(ii) $u$ is the unique solution of (29) and is also the solution of (28).

(iii) $\lambda, -\{u > 0\}, -u'(b)$ and $u'(a')$ only depend on $a$ and $b$ through $(b - a)$ and are decreasing functions of $b - a$.

(iv) There exists $\ell_c > 0$ such that $\{u > 0\} = (a, b)$ if and only if $b - a \leq \ell_c$.

Furthermore, $u'(a) > 0$ if and only if $b - a < \ell_c$.

The critical length $\ell_c$ is the longest possible length of the support of the drop. We recall that it depends on $V_0$, $\kappa$ and $\alpha$. It will play a very important role in the analysis of our problem.

In view of (iii), we can define

$$G(b - a) := \frac{1}{2}|u'(a)|^2, \quad H(b - a) := \frac{1}{2}|u'(b)|^2,$$

where $u$ is the solution of (29). The functions $\ell \mapsto G(\ell)$ and $\ell \mapsto H(\ell)$ are then both monotone decreasing, and multiplying equation (29) by $u'$ and integrating over $(a', b)$ yields

$$\frac{1}{2} u'(b)^2 - \frac{1}{2} u'(a')^2 = \kappa \sin \alpha V_0$$

or

$$H(\ell) - G(\ell) = \kappa \sin \alpha V_0.$$  

We also define

$$F : \ell \mapsto G(\ell) + H(\ell),$$

which is a decreasing function as well.

Finally, we have the following lemmas, which will be useful later on:

**Lemma 3.6** (Lipschitz regularity). For all $\delta_0 > 0$, there exists $C > 0$ such that

$$0 \leq H(\ell_0) - H(\ell_0 + \eta) \leq C\eta$$

and

$$0 \leq G(\ell_0) - G(\ell_0 + \eta) \leq C\eta$$

for $\ell_0 \geq \delta_0$ and $\eta \geq 0$. In particular, it follows that $H$ and $G$ (and therefore $F$) are locally Lipschitz on $(0, \infty)$.

**Lemma 3.7** (Non-degeneracy). For all $\delta_0 > 0$ there exists $c > 0$ such that

$$H(\ell_0) - H(\ell_0 + \eta) \geq c\eta$$

for all $\ell_0 \leq \ell_c - \delta_0$ and $\eta$ such that $\ell_0 + \eta \leq \ell_c$.

Next, we consider the following boundary value problem with volume constraint:

$$
\begin{cases}
-v'' = \lambda - v\kappa \cos \alpha + (x - b)\kappa \sin \alpha & \text{in } (a, b), \\
v(a) = v(b) = 0 & \text{and } \int v \, dx = V_0,
\end{cases}
$$

where $\lambda$ is a Lagrange multiplier for the volume constraint. Then, we have:

**Proposition 3.8.** Let $v$ be the solution of (33). Then there exists $\ell_c$ depending on $V_0$, $\alpha$ and $\kappa$ such that the followings are equivalent:

(i) $v'(a) \geq 0$, 

(ii) $v'(b) \leq 0$.

The critical length $\ell_c$ is the longest possible length of the support of the drop. We recall that it depends on $V_0$, $\kappa$ and $\alpha$. It will play a very important role in the analysis of our problem.
Furthermore, $v'(a) > 0$ if and only if $b - a < \ell_c$.

This proposition implies Proposition 3.4.

The remainder of this section is devoted to the proof of these results.

Proof of Proposition 3.5

(i) Let $(c, d)$ be a connected component of $\{u > 0\}$. Then

\begin{equation}
-u'' = \lambda + (x - b)\kappa \sin \alpha - u\kappa \cos \alpha
\end{equation}

in $(c, d)$. Multiplying (35) by $u'$ and integrating over $(c, d)$ yields

$$u'(d)^2 = u'(c)^2 + 2\kappa \sin \alpha \int_c^d u \, dx > 0.$$  

If $d \neq b$, then the regularity of $u$ implies $u'(d)^2 = 0$, a contradiction. So $d = b$, $|u'(b)| > 0$ and $(c, b)$ is the only connected component of $\{u > 0\}$. We also have the following formula:

\begin{equation}
-u'' = \lambda_1 - \lambda_2 - v\kappa \cos \alpha \quad \text{in} \quad (a_1', b).
\end{equation}

(ii) To prove the uniqueness of the solution of (29), we assume that $u_1, u_2$ are two solutions of (29) (with $\lambda_1$ and $\lambda_2$ respectively). We know that $\{u_i > 0\} = (a_i', b)$ and we can assume (without loss of generality) that $a \leq a_2' \leq a_1'$.

If $v = u_1 - u_2$, then

$$-v'' = \lambda_1 - \lambda_2 - v\kappa \cos \alpha \quad \text{in} \quad (a_1', b).$$

Furthermore, $v(a_1') \leq 0$, $v(b) = 0$ and $\int_{a_1'}^b v \, dx > 0$. So $v$ reaches its positive maximum value somewhere in $(a_1', b)$. We deduce

$$\lambda_1 \geq \lambda_2.$$  

Next, we note that since

$$-u''_1 \geq \lambda_1 + (x - b)\kappa \sin \alpha - u_1\kappa \cos \alpha \quad \text{in} \quad (a_2', b),$$

we also have

$$-v'' \geq \lambda_1 - \lambda_2 - v\kappa \cos \alpha \geq -v\kappa \cos \alpha \quad \text{in} \quad (a_2', b),$$

with $v(a_2') = v(b) = 0$ and $\int_{a_2'}^b v \, dx = 0$. If $v \neq 0$, then $v$ has a (strictly) negative minimum value in $(a_2', b)$, a contradiction. We deduce $v = 0$ and so $u_1 = u_2$.

(iii) Equation (29) is invariant by translation, and thus the uniqueness obtained in (ii) implies that $u' \cdot + b)$ and $\lambda$ only depends on $\ell = (b - a)$ (in particular, $u'(a)$ and $-u'(b)$ only depend on $\ell$).

The proof of (ii) above also implies that $\lambda$ is a decreasing function of $(b - a)$. We now take $a_2 < a_1 < b$ and let $u_1$ (resp. $u_2$) be the solution of (29) on the interval $(a_1, b)$ (resp. $(a_2, b)$). The function $v = u_1 - u_2$ satisfies

$$v(a_1) \leq 0, \quad v(b) = 0, \quad \text{and} \quad \int_{a_1}^b v \geq 0,$$
so there exists a point \( x_0 \in [a, b) \) such that \( v(x_0) = 0 \). Since
\[
-v'' + v\kappa \cos \alpha = \lambda_1 - \lambda_2 \geq 0 \quad \text{in } (x_0, b),
\]
the maximum principle gives \( v \geq 0 \) in \((x_0, b)\). In particular, \( -v'(b) \geq 0 \), and so
\[
-u_1'(b) \geq -u_2'(b).
\]
Finally, if \( u_2'(a_2) = 0 \), then \( u_2'(a_2) \leq u_1'(a_1) \), while if \( u_2'(a_2) > 0 \), then (36) implies
\[
u_2'(a_2)^2 = u_2'(b)^2 - 2\kappa \sin \alpha V_0
\]
and
\[
u_1'(a_1)^2 = u_1'(b)^2 - 2\kappa \sin \alpha V_0 \geq u_2'(b)^2 - 2\kappa \sin \alpha V_0 = u_2'(a_2)^2.
\]
Hence \( a_1' = a_1 \) and \( u_1'(a_1) \geq u_2'(a_2) \).

(iv) Note that if \( \{u > 0\} \neq (a, b) \), then \( u \) is the unique solution of (29) in any interval larger than \( (a, b) \). So we can define
\[
\ell_c := \min\{\ell \mid \text{the solution of (29) in } (0,\ell) \text{ satisfies } \{u > 0\} \neq (0,\ell)\}.
\]
We only need to show that this set is non-empty (that is \( \ell_c < \infty \)) and is equivalent to \( u'(a) \neq 0 \).

Assume that \( \{u > 0\} \neq (a, b) \). Then
\[
-u'' \leq \lambda + (x - b)\kappa \sin \alpha \quad \text{in } (a, b),
\]
and so
\[
-u'(b) + u'(a) \leq \lambda (b - a) - \frac{1}{2} (b - a)^2 \kappa \sin \alpha.
\]
Since \( u'(a) \geq 0 \) and \( u'(b) \leq 0 \), we deduce
\[
(b - a)\kappa \sin \alpha \leq \lambda.
\]
Since \( \lambda \) is a decreasing function of \( (b - a) \), this implies that \( (b - a) \leq C \) for some constant \( C \).

Finally, we note that if \( b - a < \ell_c \), then \( u'(a) > 0 \), while the regularity of \( u \) implies \( u'(a) = 0 \) when \( b - a \geq \ell_c \).

We now turn to the proof of the Lipschitz regularity of the functions \( G \) and \( H \):

**Proof of Lemma 3.6** Note that \( H \) and \( G \) are constant for \( \ell \geq \ell_c \), so we can always assume that
\[
d_0 \leq \ell_0 \leq \ell + \eta \leq \ell_c.
\]
We now consider the solution \( u \) of (29) with \( a = 0 \) and \( b = \ell_0 \), and we denote by \( \lambda(\ell_0) \) the Lagrange multiplier appearing in (29). We recall that \( \lambda \) is a decreasing function of \( \ell_0 \), and we claim that
\[
\lambda(\ell_0) - \lambda(\ell_0 + \eta) \leq C\eta
\]
for some constant \( C \) depending on \( d_0 \). To prove this, we consider \( v \) a solution of the same equation as \( u \) (with the same \( \lambda \)) but on the interval \((0,\ell_0 + \eta)\) instead of \((0,\ell_0)\):
\[
-v'' = \lambda(\ell_0) + (x - \ell_0)\kappa \sin \alpha - v\kappa \cos \alpha \quad \text{in } (0,\ell_0 + \eta), \quad v(0) = v(\ell_0 + \eta) = 0.
\]
We note that \( v \geq u \) and that the function \( h = v - u \) solves
\[
h\kappa \cos \alpha - h'' = 0 \quad \text{on } (0,\ell_0).
\]
In particular, on the interval \((0, \ell_0)\), \(h\) must take its positive maximum at \(x = \ell_0\). Now on \((\ell_0, \ell_0 + \eta)\) we have \(h = v \leq C_1 \eta\) for some \(C_1 > 0\) with \(C_1\) depending on \(\delta_0\). We conclude that \(h \leq C_1 \eta\) in \((0, \ell_0 + \eta)\), and thus

\[
\int v \, dx \leq V_0 + C'_1 \eta
\]

for some constant \(C'_1\) depending on \(\delta_0\) and \(\ell_c\) (recall that \(\ell_0 + \eta \leq \ell_c\)).

Next, we consider \(w\) the solution of \((29)\) with \(a = 0\) and \(b = \ell_0 + \eta\) (and so \(\lambda = \lambda(\ell_0 + \eta)\)). The function \(g = v - w\) solves

\[
g \kappa \cos \alpha - g'' = \sigma
\]

in \((0, \ell_0 + \eta)\), with \(g(0) = g(\ell_0 + \eta) = 0\), where (since \(\lambda\) is decreasing)

\[
\sigma = \lambda(\ell_0) - \lambda(\ell_0 + \eta) + \eta \kappa \sin \alpha > 0.
\]

Finally, we note that the solution of \(-\phi'' = \mu \sigma\) in \((0, \ell_0 + \eta)\) with zero boundary condition satisfies \(\phi \kappa \cos \alpha - \phi'' \leq \sigma\), if \(\mu\) is small enough. The comparison principle thus implies that \(g \geq \phi\), and so

\[
\int g \, dx = \int v \, dx - V_0 \geq \int \phi \, dx \geq C \mu \sigma
\]

for some small \(\mu > 0\). Equation (39) implies

\[
C'_1 \eta \geq C \mu \sigma,
\]

and so

\[
\lambda(\ell_0) - \lambda(\ell_0 + \eta) \leq C \eta,
\]

which proves (38).

We can now prove the Lipschitz bounds for the functions \(H\) and \(G\) by comparing \(u\) (the solution of \((29)\) on \((0, \ell_0)\)) and \(w\) (the solution of \((29)\) on \((0, \ell_0 + \eta)\)): The function \(q(x) = u(x) - w(x)\) solves

\[
q \kappa \cos \alpha - q'' = \phi(\ell_0) - \phi(\ell_0 + \eta) + \eta \kappa \sin \alpha, \quad \text{in} \ (0, \ell_0)
\]

with \(q(0) = 0\) and \(q(\ell_0) = -w(\ell_0) \leq 0\). So (38) implies

\[
q \kappa \cos \alpha - q'' \leq C \eta, \quad \text{in} \ (0, \ell_0), \quad \text{with} \ q(0) = 0 \text{ and } q(\ell_0) \leq 0.
\]

We deduce \(q'(0) \leq C \eta\), and so

\[
u'(0) \leq w'(0) + C \eta,
\]

which proves our statement for \(G\). The proof for \(H\) is similar (fixing \(b = 0\) and choosing \(a = -\ell_0\) or \(a = -\ell_0 - \eta\)).

The proof of Lemma 3.7 follows from a similar argument:

**Proof of Lemma 3.7.** We recall that \(\ell_0 \leq \ell_c - \delta_0\) and we fix \(b = 0\), \(a_2 = -\ell_0 + \eta\) and \(a_1 = -\ell_0\). We note that it is enough to prove (38) for \(\eta \leq (\ell_c - \ell_0)/2\), so that we can assume that \(\ell_0 + \eta \leq \ell_c - \delta_0/2\).

We now consider \(u_1\) (resp. \(u_2\)) the solution of (29) on the interval \((a_1, 0)\) (resp. \((a_2, 0)\)). The function \(h = u_1 - u_2\) satisfies in particular

\[
h(a_1) \leq 0, \quad h(0) = 0,
\]

and we are going to show that \(\max_{(a_1, 0)} h \geq c \eta\) for some \(c > 0\).
First of all, the volume constraint implies that
\begin{equation}
\int_{a_1}^{b} h \, dx = \int_{a_2}^{a_1} u_2 \, dx > 0.
\end{equation}
Furthermore, since \( \ell_0 + \eta < \ell_c - \delta_0/2 \) the monotonicity of \( G \) implies
\[ u'_2(a_2) > \sqrt{2G(\ell_c - \delta_0/2)} > 0, \]
and so \( u_2(a_1) \geq c\eta \) for some \( c > 0 \). Also, Lemma 3.6 gives
\[ h'(a_1) = u'_1(a_1) - u'_2(a_1) \]
\[ = G(\ell_0) - u'_2(a_1) \]
\[ \leq G(\ell_0 + \eta) + C\eta - u'_2(a_1) \]
\[ \leq C\eta + u'_2(a_2) - u'_2(a_1) \]
\[ \leq C\eta. \]
We deduce that there exists \( c > 0 \) such that
\begin{equation}
\int_{a_1}^{b} h \, dx = \int_{a_2}^{a_1} u_2 \, dx > 0.
\end{equation}
Furthermore, since \( \ell_0 + \eta < \ell_c - \delta_0/2 \) the monotonicity of \( G \) implies
\[ u'_2(a_2) > \sqrt{2G(\ell_c - \delta_0/2)} > 0, \]
and so \( u_2(a_1) \geq c\eta \) for some \( c > 0 \). Also, Lemma 3.6 gives
\[ h'(a_1) = u'_1(a_1) - u'_2(a_1) \]
\[ = G(\ell_0) - u'_2(a_1) \]
\[ \leq G(\ell_0 + \eta) + C\eta - u'_2(a_1) \]
\[ \leq C\eta + u'_2(a_2) - u'_2(a_1) \]
\[ \leq C\eta. \]
We deduce that there exists \( c > 0 \) such that
\begin{equation}
\int_{a_1}^{b} h \, dx = \int_{a_2}^{a_1} u_2 \, dx > 0.
\end{equation}
Finally, we have \(-h'' + h\kappa \cos \alpha = \lambda_1 - \lambda_2 \) in \((a_1, 0)\), and so (38) implies
\begin{equation}
0 \leq -h'' + h\kappa \cos \alpha \leq C\eta. \tag{42}
\end{equation}
Now consider \( g \) a solution of \(-g'' + g\kappa \cos \alpha = C \) on \((a_1, 0)\) with \( g(a_1) = -c \) and \( g'(a_1) = c \). Then (41) and (42) imply that \( h \leq \eta g \) in \((a_1, 0)\).

Now let \( y_0 \in (a_1, 0) \) be such that \( g < 0 \) in \((a_1, y_0)\) and \( g(y_0) = 0 \) \((y_0 \) only depends on the constant \( c \) and \( C \) appearing in (41) and (42). Then
\begin{equation}
\int_{a_1}^{y_0} h \, dx \leq \eta \int_{a_1}^{y_0} g \, dx \leq -c\eta \tag{43}
\end{equation}
with \( c > 0 \).

Equations (40) and (43) imply that
\[ \int_{y_0}^{a_0} h(x) \, dx \geq c\eta, \]
and so there exists a point \( z_0 \in (y_0, 0) \) where \( h(z_0) \geq c\eta \). A Hopf’s lemma type argument (using (42)) now yields \( |h''(0)| > c\eta \), and so
\[ |u'_1(0)| > |u'_2(0)| + c\eta. \]
The result follows. \( \square \)

Proof of Proposition 3.8

(i) \( \Rightarrow \) (ii) If \( v'(a) \geq 0 \), then Lemma 3.2 implies that \( v > 0 \) in \((a, b)\), and so \( v \) is also the solution of (29), and thus of (28).

(ii) \( \Rightarrow \) (iii) If \( v \) is solution of (34), then \( v \geq 0 \) in \((a, b)\), and since \( v \) cannot be a zero interval of \((a, b)\), we must have \( \{v > 0\} = (a, b) \). Proposition 3.5 (iv) gives \( b - a \leq \ell_c \).

(iii) \( \Rightarrow \) (i) Finally, if \( b - a \leq \ell_c \), then the solution \( u \) of (28) satisfies \( \{u > 0\} = (a, b) \), and is thus also a solution of (34). If follows that \( v'(a) = u'(a) \geq 0 \). \( \square \)
4. Proof of Theorem 2.2

4.1. Uniqueness and comparison principle. In this section, we prove the comparison principle, Proposition 2.3 which also implies the uniqueness part of Theorem 2.2.

Proof of Proposition 2.3. Thanks to Proposition 3.1, we can assume that \( u \) is a solution in the sense of Definition 3.3. Using the notation of (30), we can rewrite (26) as follows:

\[
\begin{cases}
\min \{ a'(t) + G(\ell(t)) - \beta(a(t)), \ell_c - \ell(t) \} = 0, \\
b'(t) = H(\ell(t)) - \beta(b(t)),
\end{cases}
\]

with \( \ell \mapsto H(\ell) \) and \( \ell \mapsto G(\ell) \) monotone decreasing. We now define

\[
f(t) = \max \{ a_1(t) - a_2(t), b_1(t) - b_2(t) \}.
\]

Since the functions \( a_i(t) \) and \( b_i(t) \) are in \( W^{1,\infty}_{loc}(0,\infty) \), \( f(t) \) is in \( W^{1,\infty}_{loc}(0,\infty) \) and we have

\[
f'(t) = \begin{cases} 
a_1'(t) - a_2'(t) & \text{if } a_1(t) - a_2(t) > b_1(t) - b_2(t) \\
b_1'(t) - b_2'(t) & \text{if } a_1(t) - a_2(t) < b_1(t) - b_2(t) \text{ a.e. } t \geq 0, \\
b_1'(t) - b_2'(t) = a_1'(t) - a_2'(t) & \text{if } a_1(t) - a_2(t) = b_1(t) - b_2(t)
\end{cases}
\]

and so

\[
f'(t) = \begin{cases} 
a_1'(t) - a_2'(t) & \text{if } \ell_2(t) > \ell_1(t), \\
b_1'(t) - b_2'(t) & \text{if } \ell_2(t) \leq \ell_1(t).
\end{cases}
\]

When \( \ell_2(t) > \ell_1(t) \), we have in particular \( \ell_1(t) < \ell_c \), and so (44) gives

\[
a_1'(t) = -G(\ell_1(t)) + \beta(a_1(t)), \quad a_2'(t) \geq -G(\ell_2(t)) + \beta(a_2(t)).
\]

We deduce

\[
f'(t) \leq \begin{cases} 
G(\ell_2(t)) - G(\ell_1(t)) + \beta(a_1(t)) - \beta(a_2(t)) & \text{if } \ell_2(t) > \ell_1(t), \\
H(\ell_1(t)) - H(\ell_2(t)) - \beta(b_1(t)) + \beta(b_2(t)) & \text{if } \ell_2(t) \leq \ell_1(t),
\end{cases}
\]

and the monotonicity of \( G \) and \( H \) implies

\[
f'(t) \leq \begin{cases} 
K|a_1(t) - a_2(t)| & \text{if } a_1(t) - a_2(t) > b_1(t) - b_2(t), \\
K|b_1(t) - b_2(t)| & \text{if } a_1(t) - a_2(t) \leq b_1(t) - b_2(t)
\end{cases}
\]

with \( K = \|\beta'\|_{L^\infty} \). We thus have

\[
f'(t) \leq K|f(t)| \text{ a.e. } t \geq 0.
\]

In particular, \( f'_+(t) \leq Kf_+(t) \) and so \( f_+(t) \leq f_+(0)e^{Kt} \), so if \( f(0) \leq 0 \), then \( f(t) \leq 0 \text{ a.e. } t \geq 0 \).

We also have \( f'_-(t) \geq -Kf'_-(t) \) and so \( f_-(t) \geq f_-(0)e^{-Kt} \), so if \( f(0) < 0 \), then \( f(t) < 0 \text{ a.e. } t \geq 0 \). The result follows. \( \square \)
4.2. **Existence of a solution.** Observe that when $\beta$ does not depend on $x$, formulation (27) implies that the problem can be reduced to solving first an equation for $\ell(t)$, of the form

\begin{equation}
\max\{\ell'(t) - [F(\ell(t)) - 2\beta], \ell(t) - \ell_c\} = 0
\end{equation}

with $F$ defined by (32), and then an equation for $b(t)$ of the form

\begin{equation}
b'(t) = H(\ell(t)) - \beta.
\end{equation}

When $\beta$ depends on $x$ however, one cannot decouple the equations for $a$ and $b$. We will thus use a discrete scheme to prove the existence of solutions in this general framework.

4.2.1. **Discrete-time scheme.** To prove the existence of a solution for the general coefficient $\beta$, we introduce a simple discrete-time scheme (simpler than the gradient flow scheme described in the introduction): For $h > 0$ small, we describe the evolution of the drop as follows:

Assume that the support of the drop at time $t_n = nh$ is the interval $(a_n, b_n)$ and denote by $u_n(x)$ the corresponding solution of (28). We define

\begin{align*}
a_{n+1/2} &= a_n + \left[\beta(a_n) - \frac{1}{2}|u_n'(a_n)|^2\right]h, \\
b_{n+1/2} &= b_n + \left[\frac{1}{2}|u_n'(b_n)|^2 - \beta(b_n)\right]h.
\end{align*}

Next, we define $u_{n+1}$ as the solution of the obstacle problem (28) with $a = a_{n+1/2}$ and $b = b_{n+1/2}$. Proposition 3.5(i) implies that there exists $a_{n+1}$ and $b_{n+1} = b_{n+1/2}$ such that

\[\{u_{n+1} > 0\} = (a_{n+1}, b_{n+1}).\]

This scheme defines a sequence of functions $\{u_n(x)\}_{n \in \mathbb{N}}$ and a sequence of intervals $\{(a_n, b_n)\}_{n \in \mathbb{N}}$. We then define $u^h(x, t)$, $a^h(t)$ and $b^h(t)$ as continuous piecewise linear functions such that

\begin{align*}
u^h(x, nh) := u_n(x), \\
a^h(nh) := a_n, b^h(nh) := b_n.
\end{align*}

Our goal is now to pass to the limit $h \to 0$.

First, we observe that since $b_{n+1} = b_{n+1/2}$, we have

\begin{equation}
\frac{b_{n+1} - b_n}{h} = \frac{1}{2}|u_n'(b_n)|^2 - \beta(b_n).
\end{equation}

On the other hand, we only have $a_{n+1} \geq a_{n+1/2}$, and if $a_{n+1} > a_{n+1/2}$, then $u_{n+1}'(a_{n+1}) = 0$. So we can write

\[\frac{a_{n+1} - a_n}{h} \geq \beta(a_n) - \frac{1}{2}|u_n'(a_n)|^2,\]

with equality if $u_{n+1}'(a_{n+1}) > 0$, which implies

\begin{equation}
\min\left\{\frac{a_{n+1} - a_n}{h} + \frac{1}{2}|u_n'(a_n)|^2 - \beta(a_n), u_{n+1}'(a_{n+1})\right\} = 0.
\end{equation}

Finally, using Proposition 3.8, we can also write

\begin{equation}
\min\left\{\frac{a_{n+1} - a_n}{h} + \frac{1}{2}|u_n'(a_n)|^2 - \beta(a_n), a_n - b_n + \ell_c\right\} = 0.
\end{equation}
4.2.2. Limit $h \to 0$. We now study the limit $h \to 0$ of the discrete model introduced above. Note that $u_n$ satisfies, for some $\lambda_n$,
\[
\begin{aligned}
- u''_n &= \lambda_n - u_n \kappa \cos \alpha + (x - b_n) \kappa \sin \alpha \quad \text{in } (a_n, b_n), \\
u_n(a_n) &= u_n(b_n) = 0, \\
\int u_n \, dx &= V_0.
\end{aligned}
\]
(50)

We then have the following proposition:

**Proposition 4.1.** For all $n$, the following holds:

(i) $|u'_n(a_n)|$ and $|u'_n(b_n)|$ are uniformly bounded. More precisely, there exists a constant $M$ depending only on $\kappa$, $\alpha$, $V_0$ and the initial data such that
\[
|u'_n(a_n)| \leq |u'_n(b_n)| \leq M.
\]

(ii) There exist constants $\ell > 0$ and $\Lambda$ depending only on $\kappa$, $\alpha$, $V_0$ such that $b_n - a_n \geq \ell$ and $|\lambda_n| \leq \Lambda$.

(iii) $a^h(t)$ and $b^h(t)$ are uniformly Lipschitz continuous with respect to $h$ and $t$.

Before proving this proposition, we show that it implies the existence of a solution (Theorem 2.2):

**Proof of Theorem 2.2** Proposition 4.1 implies that $a^h(t)$, $b^h(t)$ and $\ell^h(t) = b^h(t) - a^h(t)$ are Lipschitz continuous uniformly with respect to $h$ and that there exists $\ell$ independent of $h$ such that
\[
\ell \leq \ell^h(t) \leq \ell_c \quad \forall t \geq 0.
\]

In particular, there exists a subsequence $h \to 0$ and some Lipschitz continuous functions $a(t)$ and $b(t)$ such that
\[
a^h(t) \to a(t), \quad b^h(t) \to b(t) \quad \text{uniformly with respect to } t \in [a, b]
\]
for all $a < b \in \mathbb{R}$.

Next, we note that for any $t \geq 0$, $u^h(x, t)$ solves
\[
- u_{xx}(\cdot, t) = \lambda(\ell^h(t)) - \kappa \cos \alpha x + (x - b^h(t)) \kappa \sin \alpha, \quad \text{in } (a^h, b^h),
\]
and so the function $v^h(x, t) = u^h(a^h(t) + x \ell^h(t), t)$ solves
\[
- v_{xx}(\cdot, t) = \ell^h(t)^2 \left[ \lambda(\ell^h(t)) - \kappa \cos \alpha v + \ell^h(t)(x - 1) \kappa \sin \alpha \right], \quad \text{in } (0, 1)
\]
with
\[
v^h(0, t) = v^h(1, t) = 0.
\]

In particular, it is readily seen that $x \mapsto v^h(x, t)$ is bounded in $C^2(0, 1)$ uniformly with respect to $t$ and that $v^h$ and $v_{xx}^h$ are Lipschitz continuous with respect to $t$, uniformly with respect to $h$. Finally, $v^h$ converges locally uniformly (with respect to $x$ and $t$) to a function $v$ solution of
\[
- v_{xx}(\cdot, t) = \ell(t)^2 \left[ \lambda(\ell(t)) - \kappa \cos \alpha v + \ell(t)(x - 1) \kappa \sin \alpha \right],
\]
\text{in } (0, 1) \text{ with } v(0, t) = v(1, t) = 0.

Writing
\[
u^h(x, t) = v^h\left( \frac{x - a^h(t)}{\ell^h(t)}, t \right),
\]
we deduce that \( u^h \) converges locally uniformly (with respect to \( x \) and \( t \)) to a function \( u \) solution of
\[
-u_{xx}(\cdot, t) = \lambda(\ell(t)) - \kappa \cos \alpha u + (x - b(t))\kappa \sin \alpha, \quad \text{in } (a(t), b(t))
\]
satisfying
\[
u(a(t), t) = u(b(t), t) = 0 \quad \text{and} \quad \int u(\cdot, t)dx = V_0.
\]

Furthermore, \( u^h_x(a^h(t), t) \) and \( u^h_x(b^h(t), t) \) are Lipschitz continuous function in \( t \), uniformly with respect to \( h \). We can thus pass to the limit in (47) and (49). For instance, we note that (47) implies
\[
b^h(t) = \frac{b_{n+1} - b_n}{h} = \frac{1}{2} |u'_n(b_n)|^2 - \beta(b_n)
\]
for \( t \in (nh, (n + 1)h) \), and so the Lipschitz continuity in time implies
\[
b^h(t) = \frac{1}{2} |u'_n(b_n)|^2 - \beta(b_n) + O(h) \text{ a.e. } t \geq 0.
\]
Passing to the limit \( t \to 0 \) and repeating this argument with (49) yields (26).

**Proof of Proposition 4.1** For the sake of clarity, we drop the index \( n \) when no ambiguity is possible (so \( a = a_n \) and \( b = b_n \)).

(i) In view of Proposition 3.5 we only need to show that the length of the support \( b - a \) cannot be too small: First, if \( u'(a) = 0 \), then Proposition 3.5 (iv) implies that \( b - a = \ell_c \), and (31) gives
\[
\frac{1}{2} |u'(b)|^2 = V_0 \kappa \sin \alpha.
\]
Next, if \( u'(a) \neq 0 \), then (47) and (48) imply that the length of the interval \( b_{n+1} - a_{n+1} \) at the next time step will be given by
\[
b_{n+1} - a_{n+1} = b_n - a_n + \left[ \frac{u'(b_n)^2}{2} + \frac{u'(a_n)^2}{2} - \beta(a_n) - \beta(b_n) \right]
\]
\[
\geq b_n - a_n + \left[ \frac{u'(b_n)^2}{2} - \beta(a_n) - \beta(b_n) \right].
\]
In particular, if \( |u'(b)| \geq 2 \sup \sqrt{\beta} \), then the length of the interval increases and therefore \( |u'(b)| \) decreases. We deduce that if \( u'(a) \neq 0 \), then
\[
|u'(a)| \leq |u'(b)| \leq \max\{2 \sup \sqrt{\beta}, |u'_n(b)|\},
\]
and the result follows.

(ii) The proof of (i) above clearly implies that \( b - a \) is bounded below. Furthermore, integrating the equation satisfied by \( u \) over \( (a, b) \), we get
\[
\lambda(b - a) = u'(a) - u'(b) + V_0 \kappa \sin \alpha - \frac{1}{2} (b^2 - a^2) \kappa \sin \alpha
\]
\[
\leq 2M + V_0 \kappa \sin \alpha.
\]
The result follows.

(iii) The discrete motion law (47) and (i) imply that there exists a constant \( C > 0 \) such that
\[
\left| \frac{b_{n+1} - b_n}{h} \right| \leq C \quad \text{for all } n \geq 0.
\]
Similarly, if $|u'_{n+1}(a_{n+1})| \neq 0$, then (48) and (i) imply
\[ \left| \frac{a_{n+1} - a_n}{h} \right| \leq C \quad \text{for all } n \geq 0. \]
Finally, if $u'_{n+1}(a_{n+1}) = 0$, then $b_{n+1} - a_{n+1} = \ell_c$, and since $b_n - a_n \leq \ell_c$ we have
\[ \frac{a_{n+1} - a_n}{h} \leq \frac{b_{n+1} - b_n}{h} \leq C, \]
and (48) implies
\[ \frac{a_{n+1} - a_n}{h} \geq \beta(a_n) - \frac{1}{2} M^2 \geq -\frac{1}{2} M^2. \]
The result follows. \( \square \)

5. ASYMPTOTIC BEHAVIOR WHEN $\beta$ IS CONSTANT:
EXISTENCE OF TRAVELING WAVE SOLUTIONS

In this section, we study the long-time behavior of the drops when $\beta$ is constant (homogeneous media) and prove Theorem 2.4.

As mentioned earlier, problem (13) is much simpler in this case since the length of the support $\ell(t) = b(t) - a(t)$ solves
\[ \max \{\ell'(t) - [F(\ell(t)) - 2\beta], \ell(t) - \ell_c\} = 0 \]
with $F$ defined by (32). Once the solution of (52) is found, the solution of (13) is fully determined by solving
\[ b'(t) = H(\ell(t)) - \beta. \]

A traveling waves type solution of (23)-(26) is a solution of the form
\[ u(x,t) = v(x - ct). \]
For such a solution, the endpoints of the support $(a(t), b(t))$ of $u$ satisfy
\[ a'(t) = c \text{ and } b'(t) = c \quad \text{for all } t \]
and the length $b(t) - a(t)$ is constant equal to some $\ell_0$. Equation (52) thus reduces to finding $\ell_0$ such that
\[ \max \{-[F(\ell_0) - 2\beta], \ell_0 - \ell_c\} = 0. \]
To solve this equation, we recall that $F$ is continuous and monotone decreasing on the interval $(0, \ell_c]$. So we have the following:

1. Either $F(\ell_c) < 2\beta$, in which case there exists a unique $\ell_0 < \ell_c$ such that $F(\ell_0) = 2\beta$.
2. Or $F(\ell_c) \geq 2\beta$, in which case we have $\ell_0 = \ell_c$.

This proves the existence of a unique traveling wave, and we now derive formula (19) for the speed $c$: Let $a$ and $b$ be such that $b - a = \ell_0$ and let $u$ be the corresponding solution of (7) with support $(a,b)$. If $u_x(a) > 0$, then (26) and (53) imply
\[ \frac{1}{2} |u_x(a)|^2 = \beta - c, \quad \frac{1}{2} |u_x(b)|^2 = \beta + c, \]
and so (31) yields
\[ c = \frac{1}{2} (H(\ell_0) - G(\ell_0)) = \frac{1}{2} V_0 \kappa \sin \alpha. \]
This is possible only if $\beta - c = \frac{1}{2} |u_x(a)|^2 > 0$, that is, if $\frac{1}{2} V_0 \kappa \sin \alpha < \beta$.\[ \]
If $u_x(a) = 0$, then (53), (26) and (31) imply 

$$c = H(\ell_0) - \beta = V_0 \kappa \sin \alpha - \beta.$$ 

This implies formula (19).

Finally, the stability of $\ell_0$ is an immediate consequence of the monotonicity of $F$ since it implies that any solution of (52) satisfies 

$$\ell'(t) < 0 \text{ if } \ell < \ell_0,$$

$$\ell'(t) > 0 \text{ if } \ell > \ell_0,$$

and so $\ell(t) \to \ell_0$ as $t \to \infty$. Since the profile $u(x,t)$ is completely determined by the length of the support, the convergence of $\ell(t)$ implies the uniform convergence of $u(x,t)$ to the profile of the unique traveling wave.

6. ASYMPTOTIC BEHAVIOR WHEN $\beta$ IS PERIODIC: EXISTENCE OF PULSATING TRAVELING SOLUTIONS

In this section, we investigate the long-time behavior of the solution when the function $\beta$ is periodic, and prove Theorem 2.5. This is of course more delicate than the case where $\beta$ is constant, since we cannot reduce (13) to a single equation for the length $\ell(t)$ of the support.

First, we observe that for any solution we have (using (31)):

$$a'(t) + b'(t) \geq \frac{1}{2} |u_x(b(t))|^2 - \frac{1}{2} |u_x(a(t))|^2 + \beta(a(t)) - \beta(b(t))$$ 

(55)

$$\geq V_0 \kappa \sin \alpha + \beta(a(t)) - \beta(b(t)).$$

In particular, the condition

(56)  \hspace{1cm} \max \beta - \min \beta < V_0 \kappa \sin \alpha + \delta \hspace{1cm} \text{for some } \delta > 0 

guarantees that $a'(t) + b'(t) > \delta$ for all time. This implies that no stationary solution can exist under condition (56) and that any drops must slide down the inclined plane.

In order to prove the first part of Theorem 2.5 (existence and stability of pulsating traveling solutions), we will prove that (56) actually implies that $b'(t) > 0$ for all (large enough) time and that we can thus rewrite the equations for $a(t)$ and $b(t)$ using $x = b(t)$ instead of $t$ as a parameter. We thus start with the following lemma:

**Lemma 6.1.** The function $t \mapsto b(t)$ is in $C^{1,1}$, and if (56) holds, then there exists $\eta > 0$ such that $b'(t) > \eta$ at least for $t \geq T_0 = 2 \frac{\delta}{\ell(0)}$.

**Proof.** Let $\eta \in (0, \delta/8)$ be a small number, to be chosen later. Equation (55) and condition (56) implies

(57)  \hspace{1cm} a'(t) + b'(t) > \delta, \hspace{1cm} \text{for all } t \geq 0.

So as long as $b'(t) \leq \eta$, we have $a'(t) \geq \delta - \eta$, and thus 

$$\ell'(t) = b'(t) - a'(t) \leq -\delta + 2\eta \leq -\delta/2.$$ 

In particular, we cannot have $b'(t) \leq \eta$ in $(0, T_0)$ (with $T_0 = 2 \frac{\delta}{\ell(0)}$), or the length of the droplet would shrink to a point.

Therefore if the lemma is false, then there exists $t_0 > t_1$ such that $b'(t_0) = \eta$ and $b'(t) \geq \eta$ for $t \in (t_1, t_0)$. Next, we note that $t \mapsto \ell(t)$ and $t \mapsto b(t)$ are
Lipschitz continuous, and so (44) implies that \( t \mapsto b'(t) \) is also Lipschitz continuous. Therefore, there exists \( h \leq \frac{2\eta}{K} \) (where \( K \) is the Lipschitz constant of \( b' \)) such that
\[
b'(t) < 2\eta \quad \text{for } t \in (t_0 - h, t_0).
\]
Proceeding as before (using the fact that \( \eta < \delta/8 \)), we deduce that
\[
\ell'(t) < -\delta/2 \quad \text{for } t \in (t_0 - h, t_0),
\]
and so
\[
\ell(t_0) < \ell(t_0 - h) - \frac{\delta}{2} h
\]
(in particular, \( \ell(t) < \ell_c \), and so \( u_x(a(t), t) > 0 \) for \( t \in (t_0 - h, t_0) \)). Lemma 3.7 implies
\[
H(\ell(t_0)) \geq H(\ell(t_0 - h)) + c_0 \delta h
\]
for some \( c_0 > 0 \). Finally, (58) implies
\[
|b(t_0) - b(t_0 - h)| \leq 2h\eta,
\]
and so (44) gives
\[
\eta = b'(t_0) = H(\ell) - \beta(b(t_0)) > H(\ell(t_0 - h)) + c_0 \delta h - \beta(b(t_0 - h)) - ||\beta'||\infty 2h\eta
\]
\[
> b'(t_0 - h) + c_0 \delta h - ||\beta'||\infty 2h\eta.
\]
Since we can always choose \( h \) such that \( b'(t_0 - h) > \eta \) (by taking \( h \leq t_0 - t_1 \)), we obtain a contradiction if we choose \( \eta \) such that
\[
\eta < \frac{c_0 \delta}{2||\beta'||\infty}.
\]

Proof of Theorem 2.3 \( \circ \). Lemma 6.1 implies that \( t \mapsto b(t) \) is bijective from \((T_0, \infty)\) onto \((b(T_0), \infty)\). We can thus re-parametrize the motion of the drop using \( x = b(t) \) as our new parameter. We now write the equation satisfied by \( y(x) = \ell(b^{-1}(x)) \):
\[
\max\{y'(x)b'(b^{-1}(x)) - [F(y(x)) - \beta(a(b^{-1}(x))) - \beta(x)], y(x) - \ell_c \} = 0.
\]
Using the fact that \( b'(b^{-1}(x)) > 0 \) and \( a(t) = b(t) - \ell(t) \), the equation can be written as
\[
\max\{y'(x) - \frac{1}{b'(b^{-1}(x))}[F(y(x)) - \beta(x - y(x)) - \beta(x)], y(x) - \ell_c \} = 0.
\]
Finally, using the equation for \( b'(t) \), we deduce that \( y \) solves
\[
(60) \quad \max\{y'(x) - \mathcal{F}(y(x), x), y(x) - \ell_c \} = 0
\]
with
\[
\mathcal{F}(x, y) = \frac{F(y(x)) - \beta(x - y(x)) - \beta(x)}{H(y(x)) - \beta(x)}.
\]
In particular, the function \((x, y) \mapsto \mathcal{F}(x, y)\) is periodic with respect to \( x \).

We now need the following lemma which will be proved later on:

Lemma 6.2. There exists a 1-periodic function \( z(x) \) such that
\[
\lim_{n \to \infty} y(n + x) = z(x).
\]
In order to conclude, we rewrite the equation for \( b(t) \) as
\[
\begin{align*}
    b'(t) &= H(y(b(t))) - \beta(b(t)) \\
        &= \mathcal{H}(b(t)) + \varphi(b(t))
\end{align*}
\]
with \( \mathcal{H}(b) := H(z(b)) - \beta(b) \) a periodic function, and \( \varphi(b) := H(y(b)) - H(z(b)) \) satisfying
\[
|\varphi(b)| \to 0 \text{ as } b \to \infty.
\]
Since \( b'(t) \geq \eta \), there exists a sequence \( t_n \to \infty \) such that \( b(t_n) = n \). Let us consider \( b_n(t) := b(t_n + t) - n \), which solves the following equation:
\[
b_n'(t) = \mathcal{H}(b_n(t)) + \varphi(b_n(t) + n), \quad b_n(0) = 0.
\]
We deduce that
\[
|b_{n+k}(t) - b_n(t)| \leq e^{Ct}(|\varphi(n)| + |\varphi(n + k)|),
\]
and thus \( \{b_n\} \) is a Cauchy sequence: it converges to a monotone increasing function \( b_\infty(t) \). Since
\[
b_n(t_{n+1} - t_n) = b_{n+1}(0) + 1,
\]
we deduce that \( t_{n+1} - t_n \) converges to the unique \( t_0 \) satisfying \( b_\infty(t_0) = 1 \) and that \( b_\infty \) is \( t_0 \)-periodic.

Hence, we can show that \( b(t) - b_\infty(t) \) converges to 0 as \( t \) goes to \( \infty \), and defining \( \ell_\infty(t) = z(b_\infty(t)) \) and \( a_\infty(t) = b_\infty(t) - \ell_\infty(t) \), we obtain a pulsating solution \( (a_\infty(t), b_\infty(t)) \).

Lastly, the uniqueness of the pulsating solution with positive speed (which is guaranteed by Lemma 6.1) follows from the comparison principle (Proposition 2.3).

\textbf{Proof of Lemma 6.2} We recall that \( y(x) \) is a bounded solution of (60). For \( n \in \mathbb{N} \), we denote \( y_n(x) = y(x + n) \). The periodicity of \( \mathcal{F} \) with respect to \( x \) implies that it is also a bounded solution of (60) with initial condition \( y_n := y(n) \).

If \( y_1 = y_0 \), then the uniqueness implies that \( y(x + 1) = y(x) \) for all \( x \) and we can take \( z(x) = y(x) \). Otherwise, if, for instance \( y_1 > y_0 \), then the uniqueness implies that \( y_1(x) \geq y_0(x) \) for all \( x \geq 0 \), and so \( y_2 = y_1(1) \geq y_0(1) - y_1 \). We deduce that \( y_2(x) \geq y_1(x) \), and iterating this argument, we get
\[
y_n(x) \leq y_{n+1}(x) \quad \text{for all } n \in \mathbb{N}.
\]
So \( \{y_n(x)\} \) is monotone and bounded, and thus there exists \( z(x) \) such that \( \lim_{n \to \infty} y_n(x) = z(x) \). Since \( y_n(x + 1) = y_{n+1}(x) \), it follows that \( z(x + 1) = z(x) \), which completes the proof.

To complete the proof of Theorem 2.5 it remains to investigate the case where
\[
(61) \quad \max \beta - \min \beta \geq V_0 \kappa \sin \alpha + \delta
\]
for some \( \delta > 0 \). The comparison principle (Proposition 2.3) implies that stationary solutions act as barriers and prevent the motion of the drop down the inclined plane. However, condition (61) does not automatically imply the existence of a stationary solution. Nevertheless, we can show that stationary solutions do not exist provided the period of \( \beta \) is small enough.
Proof of Theorem 2.5 (ii). We denote by $L$ the period of $\beta$.

We first fix $\ell_0$ such that $H(\ell_0) = \max \beta$. We note that we can always find such an $\ell_0$. Indeed, $H(\ell) \to +\infty$ as $\ell \to 0$, and using the fact that $G(\ell_c) = 0$ together with (31), we get $H(\ell_c) = V_0 \kappa \sin \alpha$. Condition (61) thus implies

$$H(\ell_c) = V_0 \kappa \sin \alpha < \max \beta$$

and the intermediate value theorem implies the existence of $\ell_0 < \ell_c$ such that $H(\ell_0) = \max \beta$.

We now fix $a$ such that $\beta(a) = \min \beta$, and we find $b \in [a + \ell_0, a + \ell_0 + L]$ such that $\beta(b) = \max \beta$ (we can always find such a $b$ thanks to the periodicity of $\beta$).

Now consider the solution of (7) with support $(a, b)$. Since $\ell_0 \leq b - a \leq \ell_0 + L$, we have

$$\frac{1}{2} |u_x|^2(b) = H(b - a) \leq H(\ell_0) = \max \beta,$$

and so (thanks to the choice of $b$)

$$\frac{1}{2} |u_x|^2(b) - \beta(b) \leq 0.$$  

(62)

We also have (using Lemma 3.6 and the fact that $\ell_0 < \ell_c$)

$$\frac{1}{2} |u_x|^2(a) = G(b - a) \geq G(\ell_0 + L) \geq G(\ell_0) - CL,$$

as long as $L \leq \frac{1}{2}(\ell_c - \ell_0)$. Finally, (61) implies

$$G(\ell_0) = H(\ell_0) - V_0 \kappa \sin \alpha = \max \beta - V_0 \kappa \sin \alpha.$$

In particular, (63) yields

$$\frac{1}{2} |u_x|^2(a) \geq \beta(a) = \min \beta$$

as soon as

$$\max \beta - \min \beta \geq V_0 \kappa \sin \alpha + CL,$$

which holds for all $L \leq \delta_0$ in view of (61). Therefore we deduce

$$\beta(a) - \frac{1}{2} |u_x|^2(a) \leq 0.$$  

(64)

The comparison principle together with (62) and (64) implies that if $a(0) \leq a$ and $b(0) \leq b$, then the corresponding solution will satisfy

$$a(t) \leq a \text{ and } b(t) \leq b \text{ for all } t \geq 0,$$

hence the result. □

7. Homogenization of the velocity law

We now prove our last result, Theorem 2.7. Recall that the function $r(q)$ is defined for all $q \neq 0$ as in (21), as the effective speed of the global (periodic) solution of the ODE

$$x'(t) = q - \beta(x(t))$$

(65)

(see Lemma 2.6, whose proof is provided in Appendix A).

Now, let $u^\varepsilon(x,t)$ solve the inhomogeneous problem with period $\varepsilon$ and with given initial data $u_0$. We also denote by $a^\varepsilon(t)$ and $b^\varepsilon(t)$ the left and right endpoints of the support of $u^\varepsilon$. 

Licensed to AMS. 
License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Convergence. First, we obtain a priori estimate on $u^\varepsilon$ in the same way that we did in the construction of a solution in Section 4.2.

We recall that $a^\varepsilon(t)$, $b^\varepsilon(t)$ and $\ell^\varepsilon(t) = b^\varepsilon(t) - a^\varepsilon(t)$ are Lipschitz continuous (bounded speed of the endpoints) uniformly with respect to $\varepsilon$ and there exists $\ell$ independent of $\varepsilon$ such that

$$\ell \leq \ell^\varepsilon(t) \leq \ell_c \quad \forall t \geq 0. \tag{66}$$

In particular, there exists a subsequence $\varepsilon \to 0$ and some Lipschitz continuous functions $a(t)$ and $b(t)$ such that

$$a^\varepsilon(t) \to a(t), \quad b^\varepsilon(t) \to b(t) \quad \text{uniformly with respect to } t \in [a, b]$$

for all $a < b \in \mathbb{R}$.

Next, we note that for any $t \geq 0$, $u^\varepsilon(x, t)$ solves

$$-u_{xx}(\cdot, t) = \lambda(\ell^\varepsilon(t)) - \kappa \cos \alpha u + (x - b^\varepsilon(t))\kappa \sin \alpha, \quad \text{in } (a^\varepsilon, b^\varepsilon),$$

and so the function $v^\varepsilon(x, t) = u^\varepsilon(a^\varepsilon(t) + x\ell^\varepsilon(t), t)$ solves

$$-v_{xx}(\cdot, t) = \ell^\varepsilon(t)^2 [\lambda(\ell^\varepsilon(t)) - \kappa \cos \alpha v + \ell^\varepsilon(t)(x - 1) \kappa \sin \alpha], \quad \text{in } (0, 1)$$

with

$$v^\varepsilon(0, t) = v^\varepsilon(1, t) = 0.$$

In particular, it is readily seen that $x \mapsto v^\varepsilon(x, t)$ is bounded in $C^2(0, 1)$ uniformly with respect to $t$ and that $v^\varepsilon$ and $v_x^\varepsilon$ are Lipschitz continuous with respect to $t$, uniformly with respect to $\varepsilon$. Finally, $v^\varepsilon$ converges locally uniformly (with respect to $x$ and $t$) to a function $v$ solution of

$$- v_{xx}(\cdot, t) = \ell(t)^2 [\lambda(\ell(t)) - \kappa \cos \alpha v + \ell(t)(x - 1) \kappa \sin \alpha], \quad \text{in } (0, 1) \text{ with } v(0, t) = v(1, t) = 0.$$

Writing

$$u^\varepsilon(x, t) = v^\varepsilon\left(\frac{x - a^\varepsilon(t)}{\ell^\varepsilon(t)}, t\right),$$

we deduce:

**Lemma 7.1.** The function $x \mapsto u^\varepsilon(x, t)$ is bounded in $C^2(a^\varepsilon, b^\varepsilon)$ uniformly w.r.t. $t$, and $u^\varepsilon$ and $u_x^\varepsilon$ are Lipschitz continuous with respect to $t$, uniformly with respect to $\varepsilon$. Finally, $u^\varepsilon$ converges locally uniformly (with respect to $x$ and $t$) to a function $v$ solution of

$$- u_{xx}(\cdot, t) = \lambda(\ell(t)) - \kappa \cos \alpha u + x \kappa \sin \alpha, \quad \text{in } (a(t), b(t)) \text{ with } u(a(t), t) = u(b(t), t) = 0$$

and

$$\int u(\cdot, t)dx = V_0.$$

We can now prove Theorem 2.7.

**Proof of Theorem 2.7.** We first consider the equation for $b^\varepsilon(t)$, which reads

$$b^\varepsilon'(t) = H(\ell^\varepsilon(t)) - \beta(b^\varepsilon(t)/\varepsilon).$$

Since $t \mapsto \ell^\varepsilon$ is a Lipschitz continuous function, we can also write

$$b^\varepsilon'(t) = q^\varepsilon(t) - \beta(b^\varepsilon(t)/\varepsilon).$$
with \( q^\varepsilon(t) \) a uniformly (w.r.t. \( \varepsilon \)) Lipschitz function converging (uniformly) to \( q(t) = H(\ell(t)) \).

For a given \( t_0 > 0 \), the function
\[
x^\varepsilon(t) = \frac{1}{\varepsilon} b^\varepsilon(t_0 + \varepsilon t)
\]
solves
\[
x^{\varepsilon'}(t) = q^\varepsilon(t_0 + \varepsilon t) - \beta(x^\varepsilon(t)).
\]
Since \( q^\varepsilon(t_0 + \varepsilon t) \) is Lipschitz and \( q^\varepsilon(t_0) \) converges to \( q(t_0) \), we have that for all \( \delta > 0 \), there exists \( \varepsilon_0 \) such that
\[
|q^\varepsilon(t_0 + \varepsilon t) - q(t_0)| \leq \delta + K\varepsilon t \quad \forall \varepsilon < \varepsilon_0, \quad \forall t,
\]
and so
\[
|q^\varepsilon(t_0 + \varepsilon t) - q(t_0)| \leq 2\delta \quad \forall \varepsilon < \varepsilon_0, \quad \forall |t| \leq \frac{\delta}{K\varepsilon}.
\]

It follows that
\[
x^{\varepsilon'}(t) \leq q(t_0) + 2\delta - \beta(x^\varepsilon(t)) \quad \forall \varepsilon < \varepsilon_0, \quad \forall |t| \leq \frac{\delta}{K\varepsilon}
\]
and
\[
x^{\varepsilon'}(t) \geq q(t_0) - 2\delta - \beta(x^\varepsilon(t)) \quad \forall \varepsilon < \varepsilon_0, \quad \forall |t| \leq \frac{\delta}{K\varepsilon}.
\]

Denoting by \( \varpi \) (respectively \( \varpi \)) the solution of (65) with \( q = q(t_0) + 2\delta \) (respectively \( q = q(t_0) - 2\delta \)) satisfying \( \varpi(0) = \varpi(0) = x^\varepsilon(0) \), we deduce that
\[
\varpi(t) \leq x^\varepsilon(t) \leq \varpi(t) \quad \forall \varepsilon < \varepsilon_0, \quad 0 \leq t \leq \frac{\delta}{K\varepsilon},
\]
\[
\varpi(t) \leq x^\varepsilon(t) \leq \varpi(t) \quad \forall \varepsilon < \varepsilon_0, \quad -\frac{\delta}{K\varepsilon} \leq t \leq 0.
\]

Equation (68) implies
\[
r(q(t_0) - 2\delta)t - 1 \leq x^\varepsilon(t) - x^\varepsilon(0) \leq r(q(t_0) + 2\delta)t + 1 \quad \forall \varepsilon < \varepsilon_0, \quad 0 \leq t \leq \frac{\delta}{K\varepsilon}
\]
and so
\[
r(q(t_0) - 2\delta)t - \varepsilon \leq b^\varepsilon(t_0 + t) - b^\varepsilon(t_0) \leq r(q(t_0) + 2\delta)t + \varepsilon \quad \forall \varepsilon < \varepsilon_0, \quad 0 \leq t \leq \frac{\delta}{K}.
\]

Passing to the limit \( \varepsilon \to 0 \), we deduce that
\[
r(q(t_0) - 2\delta) \leq \frac{b(t_0 + t) - b(t_0)}{t} \leq r(q(t_0) + 2\delta), \quad 0 \leq t \leq \frac{\delta}{K},
\]
and taking the limit \( t \to 0^+ \) and then \( \delta \to 0 \), we obtain (using the continuity of the function \( q \mapsto r(q) \))
\[
r(q(t_0)) \leq \liminf_{t \to 0^+} \frac{b(t_0 + t) - b(t_0)}{t} \leq \limsup_{t \to 0^+} \frac{b(t_0 + t) - b(t_0)}{t} \leq r(q(t_0)).
\]

Furthermore, using (69) instead of (68), we can show that a similar inequality holds for the limit \( t \to 0^+ \). We thus deduce that \( b \) is differentiable at \( t_0 \) and satisfies
\[
b'(t_0) = r(q(t_0)),
\]
where \( q(t_0) = H(\ell(t_0)) = \frac{1}{2} |u_x(b(t_0), t_0)|^2 \).
The equation for $a^\varepsilon(t)$ is handled in a similar fashion. Recall that

$$-a^\varepsilon(t) \leq G(\ell(t)) - \beta(a^\varepsilon(t)/\varepsilon),$$

with equality if $|u_\varepsilon^\varepsilon(a^\varepsilon(t))| > 0$.

If $\lim_{\varepsilon \to 0} |u_\varepsilon^\varepsilon(a^\varepsilon(t_0))| > 0$, then we have $|u_\varepsilon^\varepsilon(a^\varepsilon(t))| > 0$ for $t$ in a neighborhood of $t_0$ and for small $\varepsilon$, and the argument presented above applies. If $\lim_{\varepsilon \to 0} |u_\varepsilon^\varepsilon(a^\varepsilon(t_0))| = 0$, then the above argument applies, but we have $q(t_0) = 0$ and so we only get

$$-a^\varepsilon(t_0 + t) + a^\varepsilon(t_0) \leq r(2\delta) t + \varepsilon \quad \forall \varepsilon < \varepsilon_0, \quad 0 \leq t \leq \frac{\delta}{K}.$$ 

Passing to the limit $\varepsilon \to 0$, we deduce that

$$-a(t_0 + t) - a(t_0) \leq r(2\delta), \quad 0 \leq t \leq \frac{\delta}{K},$$

and taking the limit $t \to 0^+$ and then $\delta \to 0$, we obtain (using the continuity of the function $q \mapsto r(q)$)

$$\limsup_{t \to 0^+} \frac{a(t_0 + t) - a(t_0)}{t} \leq r(0)$$

and a similar limit for $t \to 0^+$.

This prove that $u^\varepsilon$ converges (up to a subsequence) to a solution of (15), (16), (22).

To complete the proof of Theorem 2.7 it remains to prove the uniqueness of the solution of the homogenized problem, which also implies the convergence of the whole sequence $u^\varepsilon$ to $u$. For that, we will show that a comparison principle similar to that of Proposition 2.3 holds (note that we cannot deduce this comparison principle by passing to the limit $\varepsilon \to 0$ in Proposition 2.3 since two solutions of the homogenized problem may be obtained by passing to the limit along different subsequences of $\varepsilon$).

Using the notation of (30) we first rewrite (22) as follows:

\begin{equation}
\begin{cases}
\min\{a'(t) + r(G(\ell(t))) + \ell(t) - \ell_c(t)\} = 0, \\
b'(t) = r(H(\ell(t))).
\end{cases}
\end{equation}

We now consider two solutions of the homogenized problem $u_1$ and $u_2$ with initial data with support $(a_1(0), b_1(0))$ and $(a_2(0), b_2(0))$ satisfying

$$a_1(0) \leq a_2(0) \quad \text{and} \quad b_1(0) \leq b_2(0).$$

We then define

$$f(t) = \max\{a_1(t) - a_2(t), b_1(t) - b_2(t)\}.$$ 

Since the functions $a_1(t)$ and $b_1(t)$ are in $W^{1,\infty}_{1,\infty}(0, \infty)$, $f(t)$ is in $W^{1,\infty}_{1,\infty}(0, \infty)$ and we have

$$f'(t) = \begin{cases} 
\frac{a_1'(t) - a_2'(t)}{\ell_2(t) - \ell_1(t)} & \text{if } \ell_2(t) > \ell_1(t), \\
\frac{b_1'(t) - b_2'(t)}{\ell_2(t) - \ell_1(t)} & \text{if } \ell_2(t) \leq \ell_1(t).
\end{cases}$$

When $\ell_2(t) > \ell_1(t)$, we have in particular $\ell_1(t) < \ell_c$, and so (70) gives

$$a_1'(t) = -r(G(\ell_1(t))), \quad a_2'(t) \geq -r(G(\ell_2(t))).$$
We deduce that
\[ f'(t) \leq \begin{cases} 
    r(G(\ell_2(t))) - r(G(\ell_1(t))) & \text{if } \ell_2(t) > \ell_1(t), \\
    r(H(\ell_1(t))) - r(H(\ell_2(t))) & \text{if } \ell_2(t) \leq \ell_1(t), 
\end{cases} \]
and the monotonicity of \( G, H \) and \( r \) implies
\[ f'(t) \leq 0. \]
We deduce that if \( f(0) \leq 0 \), then \( f(t) \leq 0 \) a.e. \( t \geq 0 \) which implies the comparison result and the uniqueness of the solution. \( \square \)

Appendix A. The function \( r(q) \): Proof of Lemma 2.6

In this section, we prove Lemma 2.6. We recall that \( \beta \) is a periodic function (with period 1 for instance), and for a given \( q \geq 0 \), we consider the following equation:
\[ (71) \]
\[ x'(t) = q - \beta(x(t)). \]
Since \( \beta \) is a Lipschitz function, (71) has a unique solution for any initial data \( x(0) = x_0 \) and the two solutions can never cross.

Our first remark is that if \( q \in [\min \beta, \max \beta] \), then any solution of (71) will be trapped in the sense that \( x(t) \in [x(0) - 1, x(0) + 1] \) for all \( t \). Indeed, periodicity of \( \beta \) implies that there exists \( x_1 \in [x(0) - 1, x(0)] \) and \( x_2 \in (x(0), x(0) + 1] \) such that \( q - \beta(x_1) \geq 0 \) and \( q - \beta(x_2) \leq 0 \). It is then easy to show that \( x(t) \in [x_1, x_2] \) for all \( t \).

In that case, the effective speed of any solutions of (71) is zero. We thus have
\[ r(q) = 0, \quad q \in [\min \beta, \max \beta]. \]
For \( q > \max \beta \) and \( q < \min \beta \), on the other hand, any solution of (71) will be strictly monotone, with \( \lim_{t \to \pm \infty} x(t) = \pm \infty \). In particular, we can then show that all solutions are equal, up to a translation in time. Assuming that \( x(0) = 0 \) (without loss of generality), there exist a unique \( t_c \) such that \( x(t_c) = 1 \). Uniqueness for (71) implies that \( t \mapsto x(t) \) is then periodic with period \( t_c \) and that its effective speed is given by
\[ r(q) = \frac{1}{t_c}. \]
We then have

Proposition A.1. The function \( r : q \mapsto r(q) \) defined above is a non-decreasing function. Furthermore,
\begin{enumerate}
\item (i) \( q \mapsto r(q) \) is locally Lipschitz in \((\max \beta, \infty)\) and \([0, \min \beta)\).
\item (ii) If \( q_0 = \max \beta \), then we have
\[ r(q) \leq C(q - q_0)^{1/2} \quad \text{for } q \geq q_0 \]
if \( x \mapsto \beta \) is \( C^2 \), and
\[ r(q) \leq C(-\ln(q - q_0))^{-1} \quad \text{for } q \geq q_0 \]
if \( x \mapsto \beta \) is only Lipschitz. In particular, \( r \) is a continuous function in \([0, \infty)\).
\end{enumerate}

Proof of Proposition A.1. To prove the first part, we consider \( q_2 > q_1 > \max \beta \) and we set \( \eta = q_2 - q_1 \). Let \( x(t) \) and \( y(t) \) be the solution of (71) with \( q = q_1 \) and \( q = q_2 \) respectively, and \( x(0) = y(0) = 0 \). Since \( x'(t) \geq q_1 - \max \beta = \delta > 0 \), we can define
\[ h(s) = y \circ x^{-1}(s) - s, \]
the solution of
\[
    h'(s) = \frac{q_1 - \beta(x + h(x)) + \eta}{q_1 - \beta(x)} - 1
\]
\[
    = \frac{\beta(x) - \beta(x + h(x)) + \eta}{q_1 - \beta(x)}
\]
\[
    \leq \frac{K}{\delta} (h(x) + \eta).
\]
Since \( h(0) = y(x^{-1}(0)) - 0 = 0 \), Gronwall’s lemma implies
(72) \(
    h(1) \leq C\eta.
\)
If we denote \( t_c \) such that \( x(t_c) = 1 \) (so that \( r(q_1) = 1/t_c \)), then (72) implies
\[
    y(t_c) \leq 1 + C\eta.
\]
Finally, since \( y'(t) \geq \delta \), this implies \( t_2 \) such that \( y(t_2) = 1 \) satisfies \( t_2 \geq t_c - C\eta \), and so
\[
    r(q_2) \leq r(q_1) + C\eta
\]
for some \( C \) depending on \( q_1 \) and \( r(q_1) \).

The constant \( C \) degenerates when \( r(q) \) goes to zero, so we need a different argument to prove (ii): Let \( \eta = q - q_0 \). Assume (with loss of generality) that \( \max \beta = \beta(0) \) (and so \( \beta'(0) = 0 \)). If \( \beta \) is \( C^2 \), then
\[
    \beta(x) \geq \beta(0) - Cx^2 = q_0 - Cx^2, \quad \text{for all } x,
\]
and so
\[
    q - \beta(x) \leq \eta + Cx^2.
\]
Now let \( x(t) \) be the corresponding solution of (71). Up to a translation in time, we can always assume that \( x(0) = 0 \). We then have
\[
    x'(t) \leq \eta + Cx(t)^2.
\]
We deduce that
\[
    x(t) \leq \frac{C\eta t}{1 - C\sqrt{\eta} t} \quad \text{for } t \leq (C\sqrt{\eta})^{-1}.
\]
In particular, \( t_c \), defined by \( x(t_c) = 1 \) satisfies
\[
    \frac{1}{t_c} \leq C(\eta + \sqrt{\eta}),
\]
hence the first result.

When \( \beta \) is only Lipschitz, a similar argument yields
\[
    x'(t) \leq \eta + Cx(t),
\]
which gives the second result. \( \square \)
