# ERROR BOUNDS FOR THE METHOD OF GOOD LATTICE POINTS 

SHAUN DISNEY AND IAN H. SLOAN

#### Abstract

New error bounds are obtained for the method of good lattice points for multidimensional quadrature, when $m$, the number of quadrature points, is prime. One of these bounds reduces the constant in Niederreiter's asymptotic error bound, if the dimension exceeds 2 . Together they give very much smaller numerical bounds for all values of $m$.

## 1. Introduction

The method of good lattice points, developed by Korobov [4] and Hlawka [3], is a well-studied method for the approximate evaluation of integrals over the $s$-dimensional unit cube $I^{s}=[0,1]^{s}$, under the assumption that the integrand is 1 -periodic in each variable. The method is reviewed by Niederreiter [7, 9].

If $f$ is such an integrand defined on $\mathbb{R}^{s}$, then the approximation is

$$
\begin{equation*}
\int_{I^{5}} f(\mathbf{x}) d \mathbf{x} \approx \frac{1}{m} \sum_{j=0}^{m-1} f\left(\frac{j}{m} \mathbf{g}\right) \tag{1.1}
\end{equation*}
$$

where $m \geq 2$ is a (large) positive integer, and $\mathbf{g} \in \mathbb{Z}^{s}$ is an appropriate $s$ dimensional integer vector, or "lattice point". In the present work, as in the work of Korobov and Hlawka, $m$ is taken to be prime.

If $f$ has the absolutely convergent Fourier series expansion

$$
\begin{equation*}
f(\mathbf{x})=\sum_{\mathbf{h} \in \mathbb{Z}^{s}} a_{\mathbf{h}} e^{2 \pi i \mathbf{h} \cdot \mathbf{x}} \tag{1.2}
\end{equation*}
$$

then, as is well known, the error in (1.1) is

$$
\begin{equation*}
\frac{1}{m} \sum_{j=0}^{m-1} f\left(\frac{j}{m} \mathbf{g}\right)-\int_{I^{s}} f(\mathbf{x}) d \mathbf{x}=\sum_{\substack{\mathbf{h} \neq \mathbf{0} \\ \mathbf{h} \cdot \mathbf{g} \equiv 0(\bmod m)}} a_{\mathbf{h}} \tag{1.3}
\end{equation*}
$$

Let

$$
\begin{equation*}
r(\mathbf{h})=\prod_{i=1}^{s} r\left(h_{i}\right), \quad r(h)=\max (1,|h|) \tag{1.4}
\end{equation*}
$$

[^0]From (1.3) it follows that the least upper bound of the error for the class of functions whose Fourier coefficients satisfy $\left|a_{\mathbf{h}}\right| \leq r(\mathbf{h})^{-\alpha}$ for $\mathbf{h} \neq \mathbf{0}$ is

$$
\begin{equation*}
P_{\alpha}(\mathbf{g}, m)=\sum_{\substack{\mathbf{h} \neq \mathbf{0} \\ \mathbf{h} \cdot \mathbf{g} \equiv 0(\bmod m)}} \frac{1}{r(\mathbf{h})^{\alpha}}, \quad \alpha>1 . \tag{1.5}
\end{equation*}
$$

In the method of good lattice points, for fixed $m$ and $\alpha$ one chooses a lattice point $\mathbf{g}$ which makes $P_{\alpha}(\mathbf{g}, m)$ as small as possible. (Alternative selection criteria are discussed by Lyness [5].) A result of Niederreiter (obtained by combining (4.6) of [7] with Theorem 2 of [8]) is that for $m$ prime (or a prime power) there exists a lattice point $g$ such that

$$
\begin{equation*}
P_{\alpha}(\mathbf{g}, m)<(1+2 \zeta(\alpha))^{s} \frac{(2 \log m+0.81)^{s \alpha}+1}{m^{\alpha}}=O\left(\frac{(\log m)^{s \alpha}}{m^{\alpha}}\right) . \tag{1.6}
\end{equation*}
$$

For $m$ prime, Bakhvalov [1] has even shown that a bound of order

$$
O\left((\log m)^{(s-1) \alpha} / m^{\kappa}\right)
$$

is achievable, but he does not give the constants.
In the present work we give new upper bounds on $P_{i}(\mathbf{g}, m)$ for good choices of $\mathbf{g}$. One of these (see Theorem 5) is of the same asymptotic order as (1.6), but has a smaller constant factor in front, except possibly for $s=2$.

The main results are stated in the next section, and proved in §3. Some of the results depend on making an appropriate choice of a certain parameter $\beta$. Motivations for our particular choices are given in $\S 4$. Finally, in $\S 5$ we calculate numerical values for the various bounds, and compare them with known "good" values of $P_{\alpha}(\mathbf{g}, m)$.

## 2. The main results

Our first result makes use of the mean of $P_{r k}(\mathbf{g}, m)$,

$$
\begin{equation*}
M_{c r}(m)=\frac{1}{(m-1)^{s}} \sum_{\mathbf{g} \in G} P_{c r}(\mathbf{g}, m), \quad \alpha>1 \tag{2.1}
\end{equation*}
$$

where $G$ is the set of all lattice points $\mathbf{g}=\left(g_{1}, g_{2}, \ldots, g_{s}\right)$ satisfying $-m / 2<$ $g_{j} \leq m / 2$ and $g_{j} \neq 0$ for $j=1, \ldots, s$.

Theorem 1. If $m$ is prime, then

$$
\begin{equation*}
M_{\alpha \alpha}(m)=\frac{(1+2 \zeta(\alpha))^{s}}{m}+\frac{(m-1)}{m}\left(1-\frac{2\left(1-m^{1-\alpha}\right) \zeta(\alpha)}{m-1}\right)^{s}-1 \tag{2.2}
\end{equation*}
$$

This is proved in $\S 3$, using techniques adapted from Niederreiter [8].
Since $M_{c k}(m)$ is the mean of $P_{c r}(\mathbf{g}, m)$ over $\mathbf{g}$, it is obvious that there exists a point $\mathbf{g}$ for which $P_{r r}(\mathbf{g}, m)$ is less than or equal to the mean.

Corollary 2. If $m$ is prime, then there exists a lattice point $\mathbf{g}$ such that

$$
P_{\alpha}(\mathbf{g}, m) \leq \frac{(1+2 \zeta(\alpha))^{s}}{m}+\frac{(m-1)}{m}\left(1-\frac{2\left(1-m^{1-\alpha}\right) \zeta(\alpha)}{m-1}\right)^{s}-1
$$

If $m \geq \zeta(\alpha)+1$, then an obvious inequality is

$$
1>1-\frac{2\left(1-m^{1-\alpha}\right) \zeta(\alpha)}{m-1}>1-\frac{2 \zeta(\alpha)}{m-1} \geq-1
$$

This leads to the following corollary, slightly weaker, but more transparent than the results above:

Corollary 3. If $m$ is prime and $m \geq \zeta(\alpha)+1$, then

$$
\begin{equation*}
M_{\alpha}(m) \leq(1+2 \zeta(\alpha))^{s} / m \tag{2.3}
\end{equation*}
$$

and there exists a lattice point $\mathbf{g}$ such that

$$
\begin{equation*}
P_{\gamma}(\mathbf{g}, m) \leq(1+2 \zeta(\alpha))^{s} / m \tag{2.4}
\end{equation*}
$$

The bound in Corollary 2 is only of order $O(1 / m)$ and therefore is worse than the bound (1.6) for large enough values of $m$. However, we shall see in $\S 5$ that its numerical values are useful for small and moderate values of $m$, and indeed are smaller than the bound (1.6) for all practical values of $m$.

Bounds with better asymptotic form may now be generated by a simple application of Jensen's inequality (see Hardy et al. [2, Theorem 19])

$$
\left(\sum\left|a_{i}\right|^{p}\right)^{1 / p} \leq\left(\sum\left|a_{i}\right|^{q}\right)^{1 / q}, \quad 0<q<p
$$

which implies, by (1.5),

$$
\begin{equation*}
P_{r}(\mathbf{g}, m) \leq\left(P_{\beta}(\mathbf{g}, m)\right)^{\alpha / \beta}, \quad 1<\beta<\alpha \tag{2.5}
\end{equation*}
$$

Combined with Theorem 1, this yields the following result:
Theorem 4. If $m$ is prime and $1<\beta<\alpha$, then there exists a lattice point $\mathbf{g}$ such that

$$
\begin{align*}
P_{\gamma}(\mathbf{g}, m) & \leq\left(M_{\beta}(m)\right)^{\alpha / \beta}  \tag{2.6}\\
& =\left(\frac{(1+2 \zeta(\beta))^{s}}{m}+\frac{(m-1)}{m}\left(1-\frac{2\left(1-m^{1-\beta}\right) \zeta(\beta)}{m-1}\right)^{s}-1\right)^{\alpha / \beta} . \tag{2.7}
\end{align*}
$$

In principle, the best choice of $\beta$ in Theorem 4 is that which, for given $m$ and $\alpha$, minimizes $\left(M_{\beta}(m)\right)^{\alpha / \beta}$. In $\S 4$ we provide some motivation for two nonoptimal choices,

$$
\begin{equation*}
\beta_{1}(m)=\log m /(\log m-s)=1+(\log \sqrt[y]{m}-1)^{-1} \tag{2.8}
\end{equation*}
$$

and

$$
\begin{equation*}
\beta_{2}(m)=1+(\log (\sqrt[4]{m} / b)-\log \log (\sqrt[4]{m} / b))^{-1} \tag{2.9}
\end{equation*}
$$

where

$$
\begin{equation*}
b=2 e^{-\gamma+1 / 2} \tag{2.10}
\end{equation*}
$$

and $\gamma=0.57721 \ldots$ is Euler's constant. The second of these is the better in both theory and practice, and is the one we use in association with (2.7) for obtaining numerical bounds in $\S 5$. The first choice $\beta_{1}$, on the other hand, is analytically simpler and allows us to obtain in $\S 3$ the following explicit bound:

Theorem 5. If $m$ is prime and $m>e^{s \alpha /(\alpha-1)}$, then there exists a lattice point $\mathbf{g}$ such that

$$
\begin{equation*}
P_{\alpha}(\mathbf{g}, m) \leq\left(\frac{e}{s}\right)^{s \alpha} \frac{(2 \log m+s)^{s \alpha}}{m^{\alpha}} \tag{2.11}
\end{equation*}
$$

The estimate (2.11) has the asymptotic form $C(\log m)^{s \alpha} / m^{\alpha}$, where $C=(2 e / s)^{s \alpha}$. Niederreiter's estimate (1.6) has the same asymptotic form $C^{\prime}(\log m)^{s \alpha} / m^{\alpha}$, with the different constant factor $C^{\prime}=2^{s \alpha}(1+2 \zeta(\alpha))^{s}$. The ratio

$$
\frac{C^{\prime}}{C}=\left(\left(\frac{s}{e}\right)^{\alpha}(1+2 \zeta(\alpha))\right)^{s}
$$

is greater than 1 for $\alpha \leq 2$ and $s \geq 1$, and for all $\alpha$ if $s \geq 3$; and for fixed $\alpha$ it increases faster than exponentially with $s$. The larger bounds given by (1.6) are reflected in the numerical bounds computed in $\S 5$.

## 3. Proofs

3.1. Proof of Theorem 1. Since $M_{\alpha}(m)$ is the mean of $P_{\alpha}(\mathbf{g}, m)$, all that has to be proved is the explicit expression for $M_{c}(m)$. In this proof, summations over $h$ and $h$ will be over $\mathbb{Z}^{s}$ and $\mathbb{Z}$, unless specifically restricted. The notation $\sum^{*}$ stands for summation excluding zero.

We have

$$
\begin{aligned}
M_{\alpha}(m) & =\frac{1}{(m-1)^{s}} \sum_{\mathbf{g} \in G} \sum_{\substack{\mathbf{h} \neq \mathbf{0} \\
\mathbf{h} \cdot \mathbf{g} \equiv 0(\bmod m)}} \frac{1}{r(\mathbf{h})^{\alpha}} \\
& =\frac{1}{(m-1)^{s}} \sum_{\mathbf{h}} N(\mathbf{h}) \frac{1}{r(\mathbf{h})^{\alpha}}-1
\end{aligned}
$$

where $N(\mathbf{h})$ is the number of vectors $\mathbf{g} \in G$ such that $\mathbf{h} \cdot \mathbf{g} \equiv 0(\bmod m)$.
We can express $N(\mathbf{h})$ as

$$
N(\mathbf{h})=\sum_{\mathbf{g} \in G} \frac{1}{m} \sum_{j=0}^{m-1} e\left(\frac{j}{m} \mathbf{h} \cdot \mathbf{g}\right)
$$

where $e(t)$ denotes $e^{2 \pi i t}$. Then we have

$$
\begin{aligned}
M_{\alpha}(m)= & \frac{1}{m(m-1)^{s}} \sum_{j=0}^{m-1} \sum_{\mathbf{h}} \sum_{\mathbf{g} \in G} e\left(\frac{j}{m} \mathbf{h} \cdot \mathbf{g}\right) \frac{1}{r(\mathbf{h})^{\alpha}}-1 \\
= & \frac{1}{m(m-1)^{s}} \sum_{j=0}^{m-1} \sum_{h_{1}=-\infty}^{\infty} \cdots \sum_{h_{s}=-\infty}^{\infty} \\
& -m / 2<g_{1} \leq m / 2 \\
* & \cdots \sum_{-m / 2<g_{s} \leq m / 2}^{*} \frac{e\left((j / m) h_{1} g_{1}\right) \cdots e\left((j / m) h_{s} g_{s}\right)}{r\left(h_{1}\right)^{\alpha} \cdots r\left(h_{s}\right)^{\alpha}}-1 \\
= & \frac{1}{m} \sum_{j=0}^{m-1}\left(\frac{1}{m-1} \sum_{h-m / 2<g \leq m / 2} \sum^{*} \frac{e((j / m) h g)}{r(h)^{\alpha}}\right)^{s}-1 .
\end{aligned}
$$

Separating out the $j=0$ term, we get

$$
\begin{equation*}
M_{\alpha}(m)=\frac{1}{m}(1+2 \zeta(\alpha))^{s}+\frac{1}{m} \sum_{j=1}^{m-1}\left(\frac{1}{m-1} T(j)\right)^{s}-1 \tag{3.1}
\end{equation*}
$$

where

$$
T(j)=\sum_{h-m / 2<g \leq m / 2} \sum^{*} e\left(\frac{j}{m} h g\right) \frac{1}{r(h)^{\alpha}}, \quad 1 \leq j \leq m-1
$$

Separating out the terms with $h \equiv 0(\bmod m)$, we have

$$
\begin{aligned}
T(j)= & \sum_{h} \frac{1}{r(h m)^{\alpha}} \sum_{-m / 2<g \leq m / 2}^{*} 1 \\
& +\sum_{h \neq 0(\bmod m)} \frac{1}{r(h)^{\alpha}} \sum_{-m / 2<g \leq m / 2}^{*} e\left(\frac{j}{m} h g\right) \\
= & (m-1) \sum_{h} \frac{1}{r(h m)^{\alpha}}-\sum_{h \neq 0(\bmod m)} \frac{1}{r(h)^{\alpha}} \\
= & (m-1)\left(1+\frac{2}{m^{\alpha}} \zeta(\alpha)\right)-\left(\sum_{h \neq 0} \frac{1}{r(h)^{\alpha}}-\sum_{h}^{*} \frac{1}{r(h m)^{\alpha}}\right) \\
= & (m-1)\left(1+\frac{2}{m^{\alpha}} \zeta(\alpha)\right)-2\left(\zeta(\alpha)-\frac{1}{m^{\alpha}} \zeta(\alpha)\right) \\
= & (m-1)-2\left(1-m^{1-\alpha}\right) \zeta(\alpha) .
\end{aligned}
$$

Putting this into (3.1) gives (2.2).

### 3.2. Proof of Theorem 5. If $m \geq 1, s \geq 1$, then

$$
m \geq \frac{1}{s} \log m+1=\frac{1}{\beta_{1}(m)-1}+2
$$

which, together with the inequality

$$
\begin{equation*}
\zeta(t)=\sum_{1}^{\infty} \frac{1}{n^{t}}<1+\int_{1}^{\infty} \frac{1}{x^{t}} d t=\frac{1}{t-1}+1, \quad t>1 \tag{3.2}
\end{equation*}
$$

implies that $m>\zeta\left(\beta_{1}(m)\right)+1$ for all $m \geq 1, s \geq 1$, where $\beta_{1}(m)$ is given by (2.8). It follows that Corollary 3 is applicable with $\alpha$ replaced by $\beta_{1}(m)$, giving

$$
M_{\beta_{1}(m)}(m) \leq\left(1+2 \zeta\left(\beta_{1}(m)\right)\right)^{s} / m
$$

The assumption $m>e^{s \alpha /(\alpha-1)}$ is equivalent to $1<\beta_{1}(m)<\alpha$, so Theorem 4 asserts the existence of a $g$ such that

$$
\begin{aligned}
P_{\alpha}(\mathbf{g}, m) & \leq\left(\frac{\left(1+2 \zeta\left(\beta_{1}(m)\right)\right)^{s}}{m}\right)^{\alpha / \beta_{1}(m)}<\frac{\left(2\left(\beta_{1}-1\right)^{-1}+3\right)^{s \alpha / \beta_{1}}}{m^{\alpha / \beta_{1}}} \\
& =\frac{(2 \log \sqrt[s]{m}+1)^{s \alpha / \beta_{1}}}{m^{\alpha} e^{-s \alpha}}<\frac{(2 \log \sqrt[s]{m}+1)^{s \alpha}}{m^{\alpha} e^{-s \alpha}} \\
& =\left(\frac{e}{s}\right)^{s \alpha x} \frac{(2 \log m+s)^{s \alpha}}{m^{\alpha}}
\end{aligned}
$$

4. Motivation for choosing $\beta=\beta_{1}$ and $\beta=\beta_{2}$

We begin with a one-parameter family of choices for $\beta$ in Theorem 4, namely

$$
\begin{equation*}
\beta=\log m /(\log m-c)=1+(\log \sqrt[c]{m}-1)^{-1}, \quad c>0 \tag{4.1}
\end{equation*}
$$

Proposition 6. If $m$ is prime and $\beta=\beta(m)$ is defined by (4.1), then

$$
\begin{equation*}
\left(M_{\beta}(m)\right)^{\alpha / \beta} \sim\left(\frac{2^{s} e^{c}}{c^{s}}\right)^{\alpha} \frac{(\log m)^{s \alpha}}{m^{\alpha}} \text { as } m \rightarrow \infty \tag{4.2}
\end{equation*}
$$

Proof. Using $\beta \rightarrow 1$ as $m \rightarrow \infty$ and $\zeta(t)=(t-1)^{-1}+O(1)$ as $t \rightarrow 1$ (for the latter see Whittaker and Watson [10, §13.21]), we obtain

$$
\zeta(\beta)=(\beta-1)^{-1}+O(1)=\log \sqrt[c]{m}+O(1)
$$

and hence, using (2.2),

$$
M_{\beta}=\frac{(2 \log \sqrt[c]{m})^{s}}{m}+O\left(\frac{(\log m)^{s-1}}{m}\right)
$$

Since $1 / \beta=1-c / \log m$ and $m^{-c / \log m}=e^{-c}$, the result (4.2) follows.
It is now reasonable to choose the parameter $c$ in (4.1) so as to minimize the constant factor in the asymptotic expression (4.2). Elementary calculus shows that $e^{c} / c^{s}$ is minimized by the choice $c=s$. With this choice (4.1) yields $\beta=\beta_{1}$.

The choice $\beta=\beta_{2}$ does not improve the asymptotic expression for $\left(M_{\beta}\right)^{\alpha / \beta}$ : in fact, it can be shown that the choices $\beta_{1}$ and $\beta_{2}$ both yield the same asymptotic form,

$$
\begin{equation*}
\left(M_{\beta_{1}}(m)\right)^{\alpha / \beta_{1}} \sim\left(\frac{2 e}{s}\right)^{s \alpha} \frac{(\log m)^{s \alpha}}{m^{\alpha}}, \quad i=1,2 \tag{4.3}
\end{equation*}
$$

The motivation for choosing $\beta=\beta_{2}$ comes from the following more careful argument. Let $F(\beta, m)$ be the bound in Theorem 4, i.e.,

$$
\begin{equation*}
F(\beta, m)=\left(M_{\beta}(m)\right)^{\alpha / \beta} \tag{4.4}
\end{equation*}
$$

Then

$$
\begin{aligned}
\frac{\partial F}{\partial \beta}(\beta, m) & =F(\beta, m)\left(-\frac{\alpha}{\beta^{2}} \log M_{\beta}+\frac{\alpha}{\beta M_{\beta}} \frac{\partial M_{\beta}}{\partial \beta}\right) \\
& =-\frac{\alpha}{\beta^{2}} F(\beta, m) \log (H(\beta, m))
\end{aligned}
$$

where

$$
\begin{equation*}
H(\beta, m)=M_{\beta}(m) \exp \left(-\frac{\beta}{M_{\beta}(m)} \frac{\partial M_{\beta}}{\partial \beta}(m)\right) \tag{4.5}
\end{equation*}
$$

Thus, $\partial F / \partial \beta=0$ if and only if $H(\beta, m)=1$; and it can be shown that the stationary value of $F$ is in fact a minimum. The next proposition shows that the choice $\beta=\beta_{2}$ is in a certain sense asymptotically optimal, in that $H\left(\beta_{2}(m), m\right) \rightarrow 1$ as $m \rightarrow \infty$, whereas this is not true for the choice $\beta=\beta_{1}$.
Proposition 7. If $m$ is prime and $s \geq 3$, then
(i) $H\left(\beta_{1}(m), m\right) \rightarrow+\infty$ as $m \rightarrow \infty$,
(ii) $H\left(\beta_{2}(m), m\right) \rightarrow 1$ as $m \rightarrow \infty$.

Proof. Let $\zeta_{i}=\zeta\left(\beta_{i}(m)\right), \zeta_{i}^{\prime}=\zeta^{\prime}\left(\beta_{i}(m)\right)$, and $x_{i}=\left(\beta_{i}(m)-1\right)^{-1}$ for $i=$ 1,2. Then $x_{1}=\log \sqrt[s]{m}-1$ and $x_{2}=\log (\sqrt[s]{m} / b)-\log \log (\sqrt[s]{m} / b)$, and in both cases $x_{i}=\log \sqrt[5]{m}+O(\log \log m)$ as $m \rightarrow \infty$. Since

$$
\zeta(t)=(t-1)^{-1}+\gamma+\varepsilon(t)
$$

where $\varepsilon(t) \rightarrow 0$ as $t \rightarrow 1$, we have

$$
\begin{gather*}
\zeta_{i}=x_{i}+O(1) \quad \text { as } m \rightarrow \infty, \quad i=1,2  \tag{4.6}\\
1+2 \zeta_{i}=2 x_{i}\left(1+\frac{2 \gamma+1}{2 x_{i}}+o\left(\frac{1}{x_{i}}\right)\right) \quad \text { as } m \rightarrow \infty, \quad i=1,2 \tag{4.7}
\end{gather*}
$$

Also $\zeta^{\prime}(t)=-(t-1)^{-2}+O(1)$, which implies

$$
\zeta_{i}^{\prime}=-x_{i}^{2}+O(1) \quad \text { as } m \rightarrow \infty
$$

We also require

$$
\begin{equation*}
m^{1-\beta_{i}(m)}=m^{-1 / x_{i}}=m^{-1 /(\log \sqrt[5]{m}+O(\log \log m))}=e^{-s}(1+o(1)) \tag{4.8}
\end{equation*}
$$

From (2.2) and (4.8) we have

$$
\begin{align*}
M_{\beta_{i}(m)}(m)= & \frac{1}{m}\left(1+2 \zeta_{i}\right)^{s}-\frac{1}{m}\left(1+2\left(1-e^{-s}(1+o(1))\right) s \zeta_{i}\right) \\
& +O\left((\log m)^{2} / m^{2}\right) \\
= & \frac{1}{m}\left(\left(1+2 \zeta_{i}\right)^{s}-\left(1+2\left(1-e^{-s}\right) s \zeta_{i}\right)(1+o(1))\right)  \tag{4.9}\\
= & \frac{1}{m}\left(1+2 \zeta_{i}\right)^{s}\left(1+O\left(1 / x_{i}^{2}\right)\right)
\end{align*}
$$

since $s \geq 3$. Similarly, by differentiating (2.2) and applying (4.6) and (4.7) we obtain

$$
\begin{equation*}
\left.\frac{\partial M_{\beta}(m)}{\partial \beta}\right|_{\beta=\beta_{t}(m)}=-\frac{2 s}{m}\left(1+2 \zeta_{i}\right)^{s-1} x_{i}^{2}\left(1+O\left(1 / x_{i}^{2}\right)\right) \tag{4.10}
\end{equation*}
$$

Thus, the argument of the exponential function in the expression (4.5) for $H(\beta, m)$ is

$$
\begin{aligned}
\left.\frac{-\beta_{i}(m)}{M_{\beta_{i}}(m)} \frac{\partial M_{\beta}(m)}{\partial \beta}\right|_{\beta=\beta_{i}} & =\frac{\left(1+1 / x_{i}\right) 2 s x_{i}^{2}\left(1+O\left(1 / x_{i}^{2}\right)\right)}{\left(1+2 \zeta_{i}\right)\left(1+O\left(1 / x_{i}^{2}\right)\right)} \\
& =\frac{s\left(x_{i}^{2}+x_{i}+O(1)\right)}{x_{i}\left(1+(2 \gamma+1) / 2 x_{i}+o\left(1 / x_{i}\right)\right)} \\
& =s\left(x_{i}+1+O\left(\frac{1}{x_{i}}\right)\right)\left(1-\frac{2 \gamma+1}{2 x_{i}}+o\left(\frac{1}{x_{i}}\right)\right) \\
& =s\left(x_{i}+\frac{1-2 \gamma}{2}+o(1)\right)
\end{aligned}
$$

Using (4.9) and (4.11), it now follows from the definition (4.5) of $H(\beta, m)$ that

$$
H\left(\beta_{i}(m), m\right)^{1 / s}=\frac{1}{\sqrt[5]{m}}\left(2 x_{i}+O(1)\right) \exp \left(x_{i}+\frac{1-2 \gamma}{2}+o(1)\right), \quad i=1,2
$$

In particular,

$$
\begin{aligned}
H\left(\beta_{1}(m), m\right)^{1 / s} & =(2 \log \sqrt[s]{m}+O(1)) \exp \left(\frac{-1-2 \gamma}{2}+o(1)\right) \\
& \rightarrow+\infty \text { as } m \rightarrow \infty
\end{aligned}
$$

whereas

$$
\begin{aligned}
H\left(\beta_{2}(m), m\right)^{1 / s}= & \left(2 \log \frac{\sqrt[y]{m}}{b}-2 \log \log \frac{\sqrt[y]{m}}{b}+O(1)\right) \\
& \times \frac{1}{b} \exp \left(-\log \log \frac{\sqrt[y]{m}}{b}+\frac{1-2 \gamma}{2}+o(1)\right) \\
= & 2 \log \frac{\sqrt[y]{m}}{b}(1+o(1)) \frac{1}{b}\left(\log \frac{\sqrt[y]{m}}{b}\right)^{-1} \exp \left(\frac{1-2 \gamma}{2}+o(1)\right) \\
\rightarrow & \frac{2}{b} \exp \left(\frac{1-2 \gamma}{2}\right)=1 \quad \text { as } m \rightarrow \infty .
\end{aligned}
$$

## 5. Numerical estimates

In Tables 1, 2, and 3 we show numerical values of theoretical bounds for the case $\alpha=2$ and dimensions $s=3,6$, and 10 . The bounds are calculated from Theorem 1, from Theorem 4 with $\beta=\beta_{2}(m)$ (see (2.9)), and from Niederreiter's bound (1.6). Additionally, to give some perspective on what might be
achievable, we show some known "good" values of $P_{2}(\mathbf{g}, m)$ for comparable values of $m$. These are taken from the tables of Maisonneuve [6].

The tables show, perhaps surprisingly, that the bound given by Corollary 2 is a quite effective bound for all practical values of $m$, notwithstanding its inferior asymptotic behavior. The bound given by Theorem 4 with $\beta=\beta_{2}(m)$, though asymptotically better, produces a smaller bound only for values of $m$ exceeding about $10^{s+1}$, and even then makes only a modest improvement.

The bound given by (1.6) exceeds both of the other bounds by many orders of magnitude, especially when $s$ is large, and is therefore less useful as a numerical estimate.

Table 1
Bounds on $P_{2}$ for $s=3$

| $m$ | Cor. 2 | Thm. 4 <br> $\left(\beta=\beta_{2}\right)$ | Bound <br> of $(1.6)$ | "Good" values <br> of $P_{2}(\mathbf{g}, m)$ | $m$ | $\mathbf{g}$ |
