The main purpose is to find the polynomial expression in  $n$  for the sum of the first  $n$   $k$ th powers of an arithmetic progression with the leading term  $a$  and the difference  $d$ . By considering such sum  $S(k)$  to be the  $k$ th power of  $S$ , we can define the linear factorization of a "polynomial" in  $S$  by way of that of ordinary polynomials. For example,  $(S-a)(S-a-d)$  denotes  $S(2)-(2a+d)S(1)+a(a+d)S(0)$ , which can further be denoted as  $P(S-a,2;d)$ , where  $P(n,r;d)=n(n-d)(n-2d)\dots[n-(r-1)d]$ . Then we can prove the following theorem by using the mathematical induction on  $n$ .

Theorem.  $P(dn,r;d)=rdP(S-a,r-1;d)$ .

As a result, the permutation  $P(n,r)$  can be expressed as a linear combination of  $S(k)$ 's with the coefficients being functions of  $a$ ,  $d$  and  $r$  (binomial coefficients and Stirling's numbers of the first kind involving  $r$ ), from which the polynomial expression for each  $S(k)$  can be obtained explicitly. As a special case, the sum of the first  $n$   $k$ th powers of the natural numbers can be expressed as a polynomial in  $n$  with the coefficients involving Stirling's numbers of both kinds. As a side product, we have a formula to construct Stirling's numbers of the second kind from the first kind. (Received January 26, 2005)
