The classification of Lie algebras in low dimensions is well known. In some recent works, the authors have been studying the decomposition of moduli spaces of Lie algebras of low dimensions using versal deformations to understand how the moduli space is glued together. These moduli spaces decompose uniquely as a union of strata, each of which is an orbifold, and these strata are glued together by jump deformations. The decomposition scheme requires some minor realignments in the classifications of these algebras into families, as given in the literature. (Received February 16, 2006)
