

RAMIFIED COVERS AND TAME ISOMONODROMIC SOLUTIONS ON CURVES

KARAMOKO DIARRA, FRANK LORAY

ABSTRACT. In this paper, we investigate the possibility of constructing isomonodromic deformations by ramified covers. We give new examples and prove a classification result.

INTRODUCTION

Let X be a complete curve of genus g over \mathbb{C} and D be a reduced divisor on X : $D = [x_1] + \dots + [x_n]$ is equivalent to the data of n distinct points on X . Set $N := 3g - 3 + n$; if $N > 0$, which we will assume along the paper, then N is the dimension of the deformation space $M_{g,n}$ of the pair (X, D) .

Let (E, ∇) be a rank 2 logarithmic connection over X with polar divisor D . In other words, $E \rightarrow X$ is a rank 2 holomorphic vector bundle and $\nabla : E \rightarrow E \otimes \Omega_X^1(D)$ a linear meromorphic connection having simple poles at the points of D . By considering the analytic continuation of a local basis of ∇ -horizontal sections of E , we inherit a monodromy representation

$$\rho_\nabla : \pi_1(X \setminus D) \rightarrow \mathrm{GL}_2(\mathbb{C})$$

(which is well defined up to conjugacy in $\mathrm{GL}_2(\mathbb{C})$).

Given a deformation $t \mapsto (X_t, D_t)$ of the complex structure, there is a unique deformation $t \mapsto (X_t, D_t, E_t, \nabla_t)$ up to bundle isomorphism such that the monodromy is constant. For t varying in the Teichmüller space $T_{g,n}$, we get the universal isomonodromic deformation (see [9]). Considering the moduli space $\mathcal{M}_{g,n}$ of quadruples (X, D, E, ∇) , isomonodromic deformations define the leaves of an N -dimensional foliation transversal to the natural projection

$$\mathcal{M}_{g,n} \rightarrow M_{g,n}; \quad (X, D, E, \nabla) \mapsto (X, D).$$

The corresponding differential equation is explicitly described in [13] (via local analytic coordinates on $M_{g,n}$) and is known to be polynomial with respect to the algebraic structure of $\mathcal{M}_{g,n}$ (it is the non-linear Gauss–Manin connection constructed in [25, Section 8]). In the case $g = 0$, we get the Garnier system (see [23]), and for $n = 4$, the Painlevé VI equation. Solutions (or leaves) are generically transcendental, and it is expected that the transcendence increase with N (see [8, Introduction] for instance). However, there are some tame solutions.

Algebraic solutions of the Painlevé VI equation were recently classified in [2, 14]. Some algebraic solutions are constructed in [5] for the Garnier case; see the discussion in the introduction of [6] for the higher genus case.

Keywords. Ordinary differential equations, isomonodromic deformations, Hurwitz spaces.

Some solutions, called “classical”, reduce to solutions of linear differential equations. They are classified in the Painlevé case in [27]. In the Garnier case, such solutions arise by considering deformations of reducible connections (see [24, 21]); they can be expressed in terms of Lauricella hypergeometric functions.

There are also “tame solutions” coming from simpler isomonodromy equations (e.g. with lower n or g). In [21], it is proved that one way of reducing n (when $g = 0$) is to consider those deformations having scalar local monodromy around some pole. There is another way of reduction, by using ramified covers, and this is what we want to investigate in this paper.

1. KNOWN CONSTRUCTIONS VIA RAMIFIED COVERS

Ramified covers of curves have already been used to construct algebraic solutions of the Painlevé VI equation (see [7, 1]) and Garnier systems (see [5]). But they have also been used to understand relations between transcendental solutions.

1.1. The most classical case is the **quadratic transformation** of the Painlevé VI equation (see [12, 19, 26, 22]). We consider a deformation $t \mapsto (E_t, \nabla_t)$ of a rank 2 connection on \mathbb{P}^1 with simple poles at $(x_1, x_2, x_3, x_4) = (0, 1, t, \infty)$. At a pole x_i , we consider eigenvalues θ_i^1, θ_i^2 of the residual matrix and call an *exponent* the difference $\theta_i := \theta_i^1 - \theta_i^2$ (defined up to a sign). To be concrete, if all $\theta_i^1 + \theta_i^2 = 0$ and the connection is irreducible, then E_t is the trivial bundle except for a discrete set of parameters (see [3]) and the connection is just defined by a two-by-two system. If moreover exponents satisfy $\theta_0 = \theta_\infty = 1/2$, then after lifting the connection on the two-fold cover

$$\mathbb{P}_{\tilde{x}}^1 \rightarrow \mathbb{P}_x^1; \quad \tilde{x} \mapsto \tilde{x}^2$$

we get a connection $(\tilde{E}_t^0, \tilde{\nabla}_t^0)$ having 6 simple poles at

$$\tilde{x} = 0, \pm 1, \pm \sqrt{t} \text{ and } \infty$$

(see Figure 1).

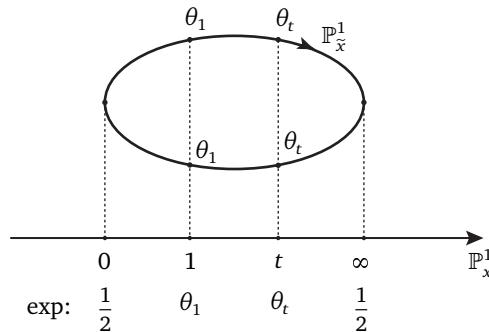

FIGURE 1. Quadratic transformation’s cover

Those two poles at ramification points $\tilde{x} = 0, \infty$ now have integral exponents and therefore scalar local monodromy $-I$. These singular points are “apparent”, i.e. can be erased by a combination of

- a rational gauge (i.e. birational bundle) transformation,
- the twist by a rank 1 connection.

This can be done by taking into account the deformation, and we get a new deformation $t \mapsto (\tilde{E}_t, \tilde{\nabla}_t)$ of a rank 2 connection with 4 simple poles $\tilde{x} = \pm 1$ and $\pm\sqrt{t}$ on the Riemann sphere $\mathbb{P}_{\tilde{x}}^1$. This new deformation is clearly isomonodromic if the initial deformation was also. Taking into account the exponents, we get a *rational two-fold cover*

$$\text{Quad: } \mathcal{M}_{0,4}\left(\frac{1}{2}, \theta_1, \theta_t, \frac{1}{2}\right) \xrightarrow{2:1} \mathcal{M}_{0,4}(\theta_1, \theta_1, \theta_t, \theta_t)$$

between moduli spaces that conjugates isomonodromic foliations. The map Quad is called a quadratic transformation of the Painlevé VI equation.

1.2. When exponents satisfy $\theta_0 = \theta_1 = \theta_\infty = 1/2$, we can iterate twice the map (after conveniently permuting the poles) and we get the **quartic transformation**

$$\text{Quad} \circ \text{Quad}: \mathcal{M}_{0,4}\left(\frac{1}{2}, \frac{1}{2}, \theta_t, \frac{1}{2}\right) \xrightarrow{4:1} \mathcal{M}_{0,4}(\theta_t, \theta_t, \theta_t, \theta_t).$$

Finally, if we consider the Picard parameters $\theta_0 = \theta_1 = \theta_t = \theta_\infty = 1/2$ for the Painlevé VI equation, we can iterate arbitrary many times the quadratic transformation. There is also a cubic transformation in this case (see [22]).

1.3. For Picard parameters

$$(\theta_0, \theta_1, \theta_t, \theta_\infty) = \left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right)$$

of the Painlevé VI equation, one can modify the construction above as follows. Now consider the elliptic two-fold cover ramifying over the 4 poles of (E_t, ∇_t) :

$$\phi_t: X_t = \{y^2 = x(x-1)(x-t)\} \xrightarrow{2:1} \mathbb{P}_x^1; \quad (x, y) \mapsto x,$$

and lift up the connection on the elliptic curve. After birational gauge transformation, we get a holomorphic connection $(\tilde{E}_t, \tilde{\nabla}_t)$ that generically splits as the direct sum of two holomorphic connections of rank 1. This means that, for these parameters, the Painlevé VI solutions actually parametrize isomonodromic deformations of rank 1 connections over a family of elliptic curves. This allows us to solve this very special element of the Painlevé VI family (originally found by Picard) by means of elliptic functions (see [11, 20, 15]). By the way, we get a *birational map*

$$\mathcal{M}_{0,4}\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right) \xrightarrow{\sim} \mathcal{M}_{1,0}$$

that commutes with isomonodromic flow.

1.4. This map has been extended to **Lamé parameters** in [16, 17] as a birational transformation

$$\text{Lamé: } \mathcal{M}_{0,4}\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \theta_\infty\right) \xrightarrow{\sim} \mathcal{M}_{1,1}(2\theta_\infty - 1),$$

also commuting with isomonodromic flow (see Figure 2).

1.5. In [10], a 2-fold ramified cover commuting with isomonodromic flow

$$\mathcal{M}_{0,6}\left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \frac{1}{2}\right) \xrightarrow{2:1} \mathcal{M}_{2,0}$$

has been constructed by lifting connections on the hyperelliptic cover

$$\phi_{r,s,t}: X_{r,s,t} = \{y^2 = x(x-1)(x-r)(x-s)(x-t)\} \xrightarrow{2:1} \mathbb{P}_x^1; \quad (x, y) \mapsto x$$

(see Figure 3).

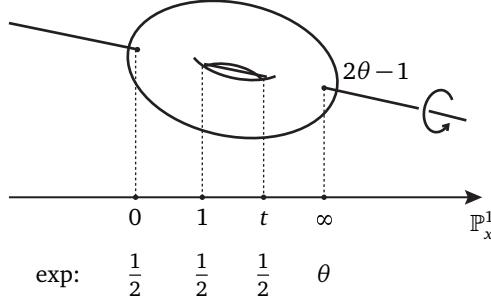

FIGURE 2. Lamé's cover

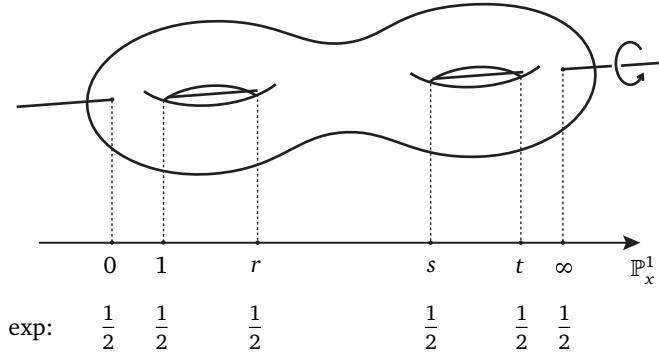

FIGURE 3. Genus 2 cover

1.6. However, for a higher genus $g > 2$ hyperelliptic curve, the similar map

$$\mathcal{M}_{0,2g+2} \left(\frac{1}{2}, \dots, \frac{1}{2} \right) \rightarrow \mathcal{M}_{g,0}$$

has a small image: not only the deformation upstairs is reduced to the hyperelliptic locus (having codimension $g - 2$), but even for a fixed hyperelliptic curve, the image has codimension $2(g - 1)$ in the moduli space of connections.

2. RESULTS

In this paper, we classify all “interesting” maps that can be constructed between moduli spaces like the one above, using ramified covers of curves. Let us explain.

Let (X, D^∇, E, ∇) be a logarithmic rank 2 connection and $\phi: \tilde{X} \rightarrow X$ be a ramified cover. Let D^ϕ denote the set of critical points of ϕ while D^∇ denotes the set of poles of ∇ ; they will be not disjoint in many cases. Consider now the universal deformation $t \mapsto (X_t, D_t)$ of the marked curve (X, D) where D is the union of D^ϕ and D^∇ . There is a unique local deformation $t \mapsto (X_t, D_t, E_t, \nabla_t, \phi_t)$ where $t \mapsto (X_t, D_t^\nabla, E_t, \nabla_t)$ is isomonodromic and $t \mapsto (X_t, D_t^\phi, \nabla_t)$ is topologically trivial (we just deform the critical locus D_t^ϕ). Fibers of the map $t \mapsto (X_t, D_t^\nabla)$ are algebraic deformations, the so-called Hurwitz families.

The main remark is that the lift to \tilde{X}_t of the connection

$$t \mapsto (\tilde{E}_t, \tilde{\nabla}_t) := \phi_t^*(E_t, \nabla_t)$$

is isomonodromic along the deformation. By applying rational gauge transformation and twisting with a rank 1 isomonodromic deformation, we may assume that $(\tilde{E}_t, \tilde{\nabla}_t)$ is an

isomonodromic deformation of the logarithmic \mathfrak{sl}_2 -connexion, free of apparent singular points. In fact, this is possible whenever ∇_t has an essential singular point, i.e. with monodromy. Let \tilde{D}_t be the (reduced) polar divisor of $\tilde{\nabla}_t$ after deleting apparent singular points. Last, but not least, assume that

- the connection (E_t, ∇_t) , or equivalently $(\tilde{E}_t, \tilde{\nabla}_t)$, has Zariski dense monodromy,
- the deformation $t \mapsto (\tilde{X}_t, \tilde{D}_t, \tilde{E}_t, \tilde{\nabla}_t)$ induces a locally universal deformation $t \mapsto (\tilde{X}_t, \tilde{D}_t)$ of the marked curve.

These are the so-called “interesting” conditions. The second item means that we get a complete isomonodromic deformation after the construction. We thus get a complete parametrization of a leaf of the isomonodromic foliation. All examples listed in Section 1 are examples of such constructions. It is easy to construct many examples where all conditions but the last one are satisfied. However, the last condition, saying that we get the complete deformation, is so hard to realize that we are able, in Section 3, to classify all examples. This is our main result in this paper. Besides the known examples, we have the following three new cases.

2.1. Let $s \mapsto X_s = \{y^2 = x(x-1)(x-s)\}$ be the Legendre family of elliptic curves and let $t \mapsto (E_t, \nabla_t)$ be an isomonodromic deformation of a rank 2 connection with poles located at $x = 0, 1, t, \infty$. More rigorously, we should say $\tilde{t} \mapsto (E_t, \nabla_t)$, where \tilde{t} belongs to the Teichmüller space, given by the universal cover $T \rightarrow \mathbb{P}_x^1 \setminus \{0, 1, \infty\}$ in this case, and t denotes the projection of \tilde{t} on $\mathbb{P}_x^1 \setminus \{0, 1, \infty\}$. Now, assume that exponents of ∇_t take the form

$$(\theta_0, \theta_1, \theta_t, \theta_\infty) = \left(\frac{1}{2}, \frac{1}{2}, \theta, \frac{1}{2} \right).$$

Therefore, after lifting on the elliptic curve, we get a connection with 3 apparent singular points and two copies of the singular point at $x = t$. By gauge transformation, we finally get a connection $(\tilde{E}_{s,t}, \tilde{\nabla}_{s,t})$ with only two simple poles, but to get an \mathfrak{sl}_2 -connection we need to shift one of the two exponents (see Figure 4). We finally get a rational map

$$\mathbb{P}_s^1 \times \mathcal{M}_{0,4} \left(\frac{1}{2}, \frac{1}{2}, \theta_t, \frac{1}{2} \right) \rightarrow \mathcal{M}_{1,2}(\theta, \theta-1).$$

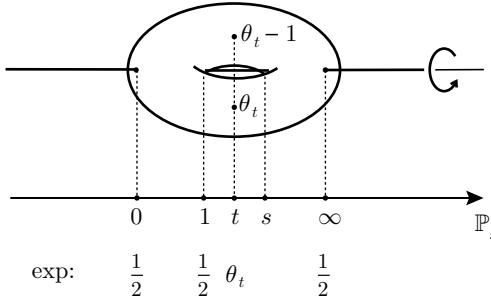

FIGURE 4. Ruled deformations via uncomplete elliptic cover

Each isomonodromic deformation thus obtained is parametrized by a combination of a Painlevé VI solution (variable t) and a rational function (variable s). We get a 2-parameter space of such tame isomonodromic deformations; they form a codimension 2 subset in $\mathcal{M}_{1,2}(\theta, \theta-1)$, the image of the map above, which is saturated by the isomonodromic foliation. The leaves belonging to this set are ruled surfaces parametrized by a Painlevé transcendent. One should recover the Lamé case of Section 1 by restricting the isomonodromic foliation to the locus $s = t$. We postpone the careful study of this picture to another paper.

2.2. Consider now the family of genus 2 curves given by

$$(s, t) \mapsto X_{s,t} = \{y^2 = x(x-1)(x-s)(x-t_1)(x-t_2)\}, \quad s \in \mathbb{C}, \quad t = (t_1, t_2) \in \mathbb{C}^2,$$

together with the hyperelliptic cover (see Figure 5)

$$\phi_{s,t}: X_{s,t} \rightarrow \mathbb{P}_x^1; \quad (x, y) \mapsto x.$$

Let $t \mapsto (E_t, \nabla_t)$ be an isomonodromic deformation of a rank 2 connection on \mathbb{P}_x^1 with poles located at five among the six critical values, namely $x = 0, 1, t_1, t_2, \infty$. Assume that all exponents of ∇_t take the form $\theta_0 = \theta_1 = \theta_{t_1} = \theta_{t_2} = \theta_\infty = 1/2$.

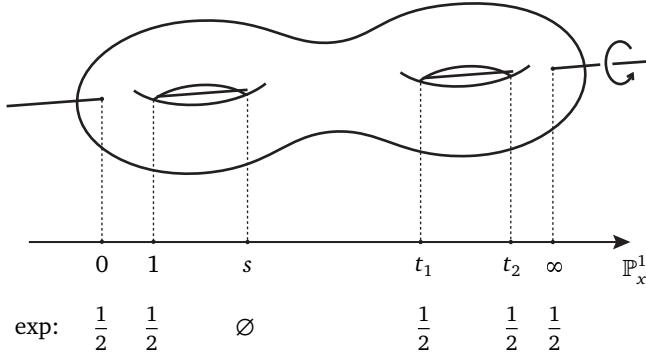

FIGURE 5. Ruled deformations via uncomplete hyperelliptic cover

After lifting the connection to the curve $X_{s,t}$, deleting apparent singular points by gauge transformation, we get an \mathfrak{sl}_2 -connection on $X_{s,t}$ with a single apparent singular point located at $x = \infty$. This provides a rational map

$$\mathbb{P}_s^1 \times \mathcal{M}_{0,5} \left(\frac{1}{2}, \dots, \frac{1}{2} \right) \rightarrow \mathcal{M}_{2,1}(1)$$

conjugating isomonodromic foliations. Here, the only singular point is apparent and it is not possible to delete it. We can just choose to place it at $x = \infty$; it is irrelevant for the deformation. Again, isomonodromic deformations obtained in this way are parametrized by rank 2 Garnier solutions ((t_1, t_2) variables) combined with a rational function of s . Again, the corresponding leaves of the isomonodromic foliation are uniruled and form a codimension 2 set.

2.3. Finally, consider the Legendre family $t_1 \mapsto X_{t_1} = \{y^2 = x(x-1)(x-t_1)\}$ of elliptic curves and let $t = (t_1, t_2) \mapsto (E_t, \nabla_t)$ be an isomonodromic deformation of a rank 2 connection with poles located at $x = 0, 1, t_1, t_2, \infty$. Assume that exponents of ∇_t take the form

$$(\theta_0, \theta_1, \theta_{t_1}, \theta_{t_2}, \theta_\infty) = \left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \theta, \frac{1}{2} \right).$$

After lifting and applying gauge transformation, we get an \mathfrak{sl}_2 -connection on the elliptic curve X_{t_1} with two simple poles over $x = t_2$ having same exponent θ . This gives us a rational map

$$\Phi_\theta: \mathcal{M}_{0,5} \left(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \theta, \frac{1}{2} \right) \rightarrow \mathcal{M}_{1,2}(\theta, \theta)$$

conjugating isomonodromic foliations (see Figure 6). We study this map from the topological (i.e. monodromy) point of view in Section 4 and deduce

Theorem 2.1. *The map Φ_θ is dominant and generically two-to-one.*

In other words, almost all rank 2 logarithmic connections with two poles on an elliptic curve is a pull-back of a rank 2 logarithmic connection on \mathbb{P}^1 ; in particular, such connections are invariant (up to gauge equivalence) under the hyperelliptic involution permuting the two poles. This construction can be thought of as intermediate between the genus two case and the Lamé case of Section 1. This is reminiscent of the hyperelliptic nature of the twice-punctured torus.

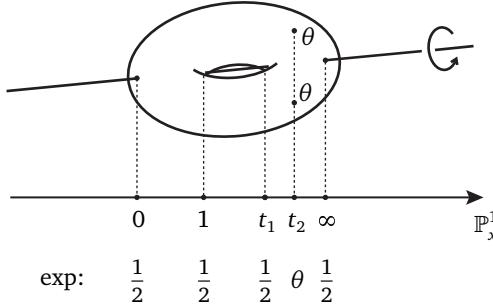

FIGURE 6. The twice-punctured torus

2.4. Classification. We prove in Section 3 the following

Theorem 2.2. *Let $t \mapsto (X_t, D_t, E_t, \nabla_t)$ be an isomonodromic deformation of logarithmic \mathfrak{sl}_2 -connections. Let $\phi_t: \tilde{X}_t \rightarrow X_t$ be a family of ramified covers. Assume that the pull-back deformation $t \mapsto (\tilde{X}_t, \tilde{D}_t, \tilde{E}_t, \tilde{\nabla}_t)$ after deleting apparent singular points is locally universal, i.e. the corresponding map $t \mapsto (\tilde{X}_t, \tilde{D}_t)$ is locally surjective. In particular, the deformation has dimension $\geq 3 \cdot \text{genus}(\tilde{X}_t) - 3 + \deg(\tilde{D}_t)$. Then we have one of the following cases:*

- The monodromy of ∇_t (or equivalently $\tilde{\nabla}_t$) is finite, reducible or dihedral.
- The deformation $t \mapsto (X_t, D_t, E_t, \nabla_t)$ is actually trivial, and we get an algebraic isomonodromic deformation by deforming ϕ_t . Up to gauge transformation, we are in the list of Doran [7] or Diarra [5]. In particular, $(X_t, D_t, E_t, \nabla_t)$ is a rigid hypergeometric system ($X_t = \mathbb{P}^1$, $\deg(D_t) = 3$) and $\deg(\phi_t) \leq 18$.
- The deformation $t \mapsto (X_t, D_t, E_t, \nabla_t)$ is non-trivial, $X_t = \mathbb{P}^1$, $\deg(\phi_t) = 2$ or 4, and we are in one of the constructions described in Sections 1.1, 1.2, 1.4, 1.5, 2.1, 2.2 and 2.3.

2.5. Complement. In the last section, we will complete the picture of Section 2.3 when $\theta = 1/2$ by constructing a rational map

$$\Psi: \mathcal{M}_{1,2} \left(\frac{1}{2}, \frac{1}{2} \right) \rightarrow \mathcal{M}_{2,0}$$

that conjugates isomonodromic foliations. In order to explain this, consider the “bi-elliptic cover”

$$\begin{array}{ccc} \tilde{X}_{t_1, t_2} & \xrightarrow{\pi_2} & X_{t_2} \\ \pi_1 \downarrow & \searrow \phi & \downarrow \phi_2 \\ X_{t_1} & \xrightarrow{\phi_1} & \mathbb{P}^1_x \end{array}$$

where $\phi_i: X_i \rightarrow \mathbb{P}^1_x$ is the elliptic two-fold cover branching over $x = 0, 1, t_i, \infty$, for $i = 1, 2$, and the remaining part of the diagram is the fiber product of ϕ_1 and ϕ_2 . In particu-

lar, \tilde{X}_{t_1, t_2} has genus 2 and each $\pi_i: \tilde{X}_{t_1, t_2} \rightarrow X_i$ is a two-fold cover branching over the two points $\phi_i^{-1}(t_j)$ (where $\{i, j\} = \{1, 2\}$). By the way, $\phi: \tilde{X}_{t_1, t_2} \rightarrow \mathbb{P}_x^1$ is a 4-fold cover ramifying over all five points $x=0, 1, t_1, t_2, \infty$.

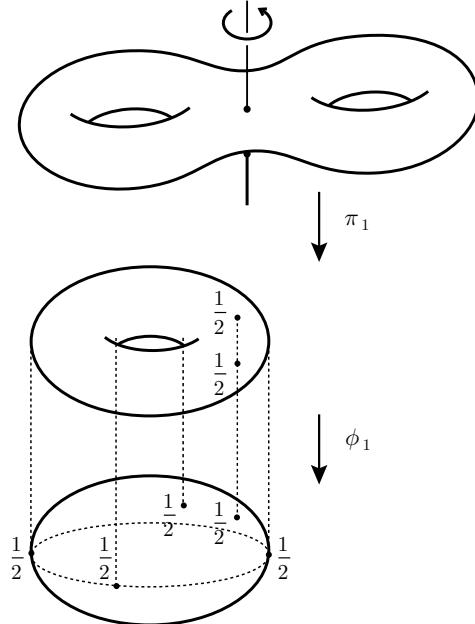

FIGURE 7. Bi-elliptic cover

The map Φ_θ of Section 2.3 comes from the elliptic covering π_1 , while the map Ψ above, from ϕ_1 in the bi-elliptic diagram. In Theorem 5.2, we characterize the image of Ψ and

$$\Psi \circ \Phi_{\frac{1}{2}}: \mathcal{M}_{0,5} \left(\frac{1}{2}, \dots, \frac{1}{2} \right) \rightarrow \mathcal{M}_{2,0}$$

in terms of the monodromy representation. Mind that, contrary to the previous constructions, we do not get complete isomonodromic deformations (of holomorphic \mathfrak{sl}_2 -connections on genus 2 curves) but rather isomonodromic deformations over the codimension 1 bi-elliptic locus in the moduli space $M_{2,0}$.

This last construction was inspired by [18], where isomonodromic deformations of dihedral logarithmic \mathfrak{sl}_2 -connections are constructed in $\mathcal{M}_{1,2}(1/2, 1/2)$ as a direct image of rank 1 holomorphic connections on the bi-elliptic cover X_{t_1, t_2} .

3. CLASSIFICATION OF COVERS

Here, we follow ideas of [5, 6], replacing connections by their underlying orbifold structure *à la Poincaré*.

Let $\phi: \tilde{X} \rightarrow X$ be a ramified cover where X is a genus g hyperbolic orbifold with n singularities of order $2 \leq \nu_1 \leq \dots \leq \nu_n \leq \infty$ (i.e. having angle $\alpha_i = 2\pi/\nu_i$). Pulling back by ϕ , we get a **branched** orbifold structure on \tilde{X} : orbifold points have angle $\tilde{\alpha} = 2\pi k/\nu$, where k is the branching order of ϕ (i.e. $\phi \sim z^k$) and

- $\nu = \nu_i$ over the i^{th} orbifold point of X ,
- $\nu = 1$ over a regular point.

Denote by \tilde{g} the genus of \tilde{X} , and by b the number of branching points on \tilde{X} . The volume of X with respect to the orbifold metric is given by

$$\text{aire}(X) = 2\pi(2g - 2) + \sum_{i=1}^n n(2\pi - \alpha_i);$$

we get an analogous formula for \tilde{X} with respect to the pull-back metric (even if α_i need not be $< 2\pi$), and $\text{aire}(\tilde{X}) = d \cdot \text{aire}(X)$ where $d = \deg(\phi)$. This yields (after division by 2π)

$$(1) \quad d \cdot \left(2g - 2 + \sum_{i=1}^n \left(1 - \frac{1}{\nu_i} \right) \right) \leq 2\tilde{g} - 2 + \sum_{j=1}^{\tilde{n}} \left(1 - \frac{k_j}{\nu_{i(j)}} \right) - b.$$

If branching points are simple (with branching order 2), then we get an equality.

We want to classify cases for which, by deforming X and ϕ simultaneously, we get the local universal deformation of \tilde{X} . The dimension of the deformation space of X is given by $3g - 3 + n \geq 0$ (positivity follows from hyperbolicity). For \tilde{X} , since we are more involved in the differential equation than in the orbifold structure, we do not take into account the branching points in the deformation, and dimension is given by $3\tilde{g} - 3 + \tilde{n}$. The dimension of deformation of the ramified cover ϕ is given by the number of “free” critical values (outside orbifold points) and thus bounded by b . We thus want

$$(2) \quad 3g - 3 + n + b \geq 3\tilde{g} - 3 + \tilde{n}.$$

On the other hand, it is reasonable to ask

$$(3) \quad 0 < 3g - 3 + n \leq 3\tilde{g} - 3 + \tilde{n}$$

first because equality $3g - 3 + n = 0$ corresponds (in the hyperbolic case) to the hypergeometric $(g, n) = (0, 3)$ that was treated in [5, 6]; right inequality just tells us that we are looking for reductions of isomonodromic equations. Throughout the paper, we will also ask $d \geq 2$ not to deal with trivial covers.

Let us first roughly reduce (1) combined with (2). In view of this, let us denote by $\nu = \nu_n$ the maximum orbifold order (that might be infinite). Then

$$\sum_{i=1}^n \left(1 - \frac{1}{\nu_i} \right) \geq \frac{n-1}{2} + \left(1 - \frac{1}{\nu} \right).$$

By the same way, we have

$$\sum_{j=1}^{\tilde{n}} \left(1 - \frac{k_j}{\nu_{i(j)}} \right) \leq \tilde{n} \left(1 - \frac{1}{\nu} \right).$$

We thus get

$$(4) \quad (2d-3)g + \frac{d-2}{2}n + \tilde{g} + \frac{\tilde{n}}{\nu} \leq d \left(\frac{3}{2} + \frac{1}{\nu} \right) - 2.$$

In fact, we have implicitly assumed $n \neq 0$. In the case $n = 0$, we automatically get $\tilde{n} = 0$ and inequality becomes

$$(2d-3)g + \tilde{g} \leq 2d - 2;$$

however, we must have $2 \leq g \leq \tilde{g}$ (hyperbolicity and growth of genus by ramified covers) that gives us $(2d-2)g \leq 2d-2$, contradiction.

3.1. First bounds. From the classical Riemann–Hurwitz formula, we necessarily get $\tilde{g} \geq g$. After (4), we thus get

$$(2d-2)g \leq d\left(\frac{3}{2} + \frac{1}{\nu}\right) - 2 \leq 2d-2.$$

Therefore, we promptly deduce $g \leq 1$. But when $g=1$, the rough inequality (4) must be an equality, yielding $g=\tilde{g}=1$ and thus (still following the Riemann–Hurwitz formula) $n=\tilde{n}=0$ and $b=0$. This case is however non-hyperbolic. *We can therefore assume $g=0$ from now on.* In particular, $n \geq 4$ from (3), and in case $n=4$, hyperbolicity implies $\nu \geq 3$.

We can also assume that either $\nu \leq d$ or $\nu = \infty$. Indeed, as soon as $\nu > d$, all points of the fiber $\phi^{-1}(p_n)$ are orbifold; we can therefore modify the orbifold structure of X , replacing ν by ∞ , without modifying the numbers n and \tilde{n} of orbifold points, and thus without changing dimensions involved in our problem.

Assume $\nu = \infty$. Then (4) gives

$$\frac{d-2}{2}n + \tilde{g} \leq \frac{3d}{2} - 2$$

and thus

$$d \leq 2 \frac{n-2-\tilde{g}}{n-3} \leq 2 \frac{n-2}{n-3}.$$

Since $d \geq 2$, we promptly deduce $\tilde{g} \leq 1$, and more precisely, we are in one of the following cases:

- $d=2$, $\tilde{g} \leq 1$ and n is arbitrary,
- $d=3$, $\tilde{g}=0$ and $n=4$ or 5 ,
- $d=4$, $\tilde{g}=0$ and $n=4$.

In particular, we get $d \leq 4$ in this case.

Assume $\nu = 2$; in this case, $n \geq 5$ because of hyperbolicity. Then (4) gives

$$d\left(\frac{n}{2}-2\right) \leq n-2-\tilde{g}-\frac{\tilde{n}}{2} \leq n-2-\tilde{g}-\frac{\tilde{n}}{3} \leq \frac{2n}{3}-2,$$

where right inequality follows from (3) $3\tilde{g}+\tilde{n} \geq n$. This gives us

$$d \leq \frac{4}{3} \cdot \frac{n-3}{n-4} < 3$$

(because $n \geq 5$) and therefore $d=2$. Taking into account (4), we get

$$\tilde{g} + \frac{\tilde{n}}{2} \leq 2.$$

This gives us the following possibilities:

- $\tilde{g}=2$ and $\tilde{n}=0$,
- $\tilde{g}=1$ and $\tilde{n} \leq 2$,
- $\tilde{g}=0$ and $\tilde{n} \leq 4$.

Assume finally that $3 \leq \nu \leq d$. Then (4) yields

$$d\left(\frac{n}{2}-2+\frac{1}{2}-\frac{1}{\nu}\right) \leq n-2-\tilde{g}-\frac{\tilde{n}}{\nu} \leq n-2-\frac{n}{\nu}-\frac{\nu-3}{\nu}\tilde{g},$$

where right inequality again follows from (3) $3\tilde{g}+\tilde{n} \geq n$. We deduce

$$d \leq 2 \frac{(n-2)\nu-n}{(n-3)\nu-2}.$$

For each $n > 4$, the right-hand side is an increasing function of ν with asymptotic

$$2 \frac{n-2}{n-3} \leq 3$$

when $\nu \rightarrow \infty$. Since $\nu < \infty$ here, we get $d < 3$ and thus $d = 2$; by the way, $\nu \leq d \leq 2$ and this case is empty. For $n = 4$, the right-hand side is 4, whatever the value of ν . Taking into account (4) for $n = 4$ and $d = 3, 4$, we get

- $\tilde{g} = 1, \tilde{n} = 1$ (and $\nu = 3$),
- $\tilde{g} = 0$ and $\tilde{n} = 4$.

3.2. Degree $d = 2$. Here, ϕ branches over $2\tilde{g} + 2$ points; recall that $\tilde{g} \leq 2$. At any orbifold point p_i , except when $\nu_i = 2$ and ϕ branches over p_i , we can assume $\nu_i = \infty$. In other words, we have

- n_1 points with $\nu_i = 2$ over which ϕ branches,
- $n_2 = n - n_1$ points with $\nu_i = \infty$ (over which ϕ needs not branching).

In the case $\nu = 2$, i.e. $n = n_1$ and $n_2 = 0$, we have already seen that $\tilde{g} \leq 2$, and thus $n \leq 2g + 2 \leq 6$. By hyperbolicity, we must have $n \geq 5$ and we get only two possibilities: X is an orbifold with 5 or 6 conical points $\nu_i = 2$ and $\phi: \tilde{X} \rightarrow X$ is a genus $\tilde{g} = 2$ branching over all conical points. **We get examples of Sections 1.5 and 2.2 respectively.**

Let us now assume $n_2 \neq 0$ and thus $\nu = \infty$. Coming back to (1) more carefully, together with (2), we get

$$n_1 + 2n_2 + \tilde{g} \leq 2 + n,$$

but since $n = n_1 + n_2$, we finally get

$$n_2 + \tilde{g} \leq 2.$$

Using the hyperbolicity assumption (and $n \geq 3$), we find the following solutions:

- $\tilde{g} = 1, n_2 = 1$ and $3 \leq n_1 \leq 4$,
- $\tilde{g} = 0, n_2 = 2$ and $n_1 = 2$.

In the first case, we decompose

- $n_1 = 4$, ϕ branches precisely over these 4 points and $\tilde{n} = 2$,
- $n_1 = 3$, ϕ branches over these 3 points and one free, and $\tilde{n} = 2$,
- $n_1 = 3$, ϕ branches over 4 orbifold points and $\tilde{n} = 1$.

We respectively get examples of Sections 2.3, 2.1, and 1.4. In the second case, ϕ branches over the two orbifold points of order 2 and $\tilde{n} = 4$ and we get example of Section 1.1.

3.3. Degree $d = 3$. We can assume orbifold points of 3 types:

- $\nu_i = 2$ and ϕ branches at the order 2 over this point; therefore, the preimage consists of one regular point (critical for ϕ) and a copy of the orbifold point.
- $\nu_i = 3$ and ϕ branches at order 3 over this point; therefore, the preimage consists of one regular point (critical for ϕ).
- $\nu_i = \infty$ and ϕ is arbitrary over this point; the preimage consists of 1, 2 or 3 copies of this point.

Denote by n_2, n_3 and n_∞ the number of these points respectively, $n_2 + n_3 + n_\infty = n$. A combination of (1) together with (2) yields (with the above notation)

$$\tilde{g} + n + n_\infty = \tilde{g} + n_2 + n_3 + 2n_\infty \leq 4.$$

This gives us $n = 4$ and $\tilde{g} = n_\infty = 0$. But in this case, the only orbifold points up-stairs have order 2, and there are at most 4 such points. This contradicts the hyperbolicity assumption.

3.4. Degree $d = 4$. We can assume orbifold orders of 4 types:

- $\nu_i = 2$ and ϕ branches at least once with order 2 over this point; then the preimage consists of one regular point (critical for ϕ) and either a second one, or two copies of the orbifold point.

- $\nu_i = 3$ and ϕ branches with order 3 over this point; then the preimage consists of one regular point (critical for ϕ) and a copy of the orbifold point.
- $\nu_i = 4$ and ϕ branches with order 4 over this point; then the preimage consists of one regular point (critical for ϕ).
- $\nu_i = \infty$ and ϕ is arbitrary over this point; therefore, the preimage consists of 1, 2, 3 or 4 copies of this point.

Denote by n_2, n_3, n_4 and n_∞ the number of these points respectively,

$$n_2 + n_3 + n_4 + n_\infty = n.$$

A combination of (1) together with (2) yields (with the above notation)

$$\tilde{g} + n_2 + 2n_3 + 2n_4 + 3n_\infty + \frac{\tilde{n}_2}{2} \leq 6$$

(here, \tilde{n}_2 is the number of orbifold points of \tilde{X} over the n_2 points of order 2). By hyperbolicity, we get $n \geq 4$ and, when $n = 4$, at least one of the orbifold points is not of minimal order 2, yielding $n + n_2 + n_3 + n_4 \geq 5$.

Assume first that $n_\infty \neq 0$; then, inequalities allow the only possibility $n = 4$ with $(n_2, n_3, n_4, n_\infty) = (3, 0, 0, 1)$, $\tilde{g} = 0$ and $\tilde{n}_2 = 0$. We get the quartic transformation for Painlevé VI (see Section 1.2).

Let us now assume $n_\infty = 0$. Recall that we want $3\tilde{g} - 3 + \tilde{n} = 3\tilde{g} - 3 + \tilde{n}_2 + n_3 \geq 1$ if $n = 4$ and ≥ 2 if $n \geq 5$. From these inequalities, the only possibility is $n = 4$ with $(n_2, n_3, n_4, n_\infty) = (3, 1, 0, 0)$, $\tilde{g} = 1$ and $\tilde{n}_2 = 0$. The covering ϕ branches only over the 4 orbifold points, is totally ramified at the order 2 over the 3 points of order 2 and has a single order 3 branching point over the point of orbifold order 3. Its monodromy, taking values into the symmetric group Σ_4 , is generated by 3 double-transpositions $(ij)(kl), \{i, j, k, l\} = \{1, 2, 3, 4\}$, whose composition has order 3. However, in Σ_4 , double-transpositions form a group (together with the identity) and cannot generate an order 3 element; such a cover does not exist.

4. FROM THE FIVE-PUNCTURED SPHERE TO THE TWICE-PUNCTURED TORUS

Fix distinct points $0, 1, t, \lambda, \infty \in \mathbb{P}^1$, and consider the elliptic cover

$$\phi: X_\lambda := \{y^2 = x(x-1)(x-\lambda)\} \rightarrow \mathbb{P}_x^1; \quad (x, y) \mapsto x;$$

denote by $\{t_1, t_2\} := \phi^{-1}(t)$ the preimage of the fifth point (note that we change notation). The orbifold fundamental group of $\mathbb{P}^1 \setminus \{0, 1, t, \lambda, \infty\}$ is defined by

$$\Gamma := \langle \gamma_0, \gamma_1, \gamma_t, \gamma_\lambda, \gamma_\infty \mid \gamma_0 \gamma_1 \gamma_t \gamma_\lambda \gamma_\infty = \gamma_0^2 = \gamma_1^2 = \gamma_\lambda^2 = \gamma_\infty^2 = 1 \rangle.$$

On the other hand, the fundamental group of the twice-punctured torus $X_\lambda \setminus \{t_1, t_2\}$ is given by

$$\tilde{\Gamma} := \langle \alpha, \beta, \delta_1, \delta_2 \mid \alpha\beta = \delta_1\beta\alpha\delta_2 \rangle.$$

The elliptic cover induces a natural monomorphism $\phi_*: \tilde{\Gamma} \rightarrow \Gamma$ identifying $\tilde{\Gamma}$ with an index two subgroup of Γ : the subgroup generated by γ_t and words of even length in letters $\gamma_0, \gamma_1, \gamma_\lambda, \gamma_\infty$. In fact, a careful study of the topological cover yields

Lemma 4.1. *The morphism ϕ_* is defined by*

$$\begin{cases} \phi_*(\alpha) = \tilde{\gamma}_1 \cdot \tilde{\gamma}_t \cdot \tilde{\gamma}_\lambda, \\ \phi_*(\beta) = \tilde{\gamma}_\lambda \cdot \tilde{\gamma}_\infty, \\ \phi_*(\delta_1) = \tilde{\gamma}_t, \\ \phi_*(\delta_2) = \tilde{\gamma}_\infty \cdot \gamma_t \cdot \gamma_\infty^{-1}. \end{cases}$$

One easily checks the compatibility between relations defining Γ and $\tilde{\Gamma}$.

Proof. If $p \in \mathbb{P}^1 \setminus \{0, 1, t, \lambda, \infty\}$ denotes the base point used to compute the fundamental group on the sphere, denote by \tilde{p} and \tilde{p}' the two lifts on the elliptic curve. For $i = 0, 1, \lambda, \infty$, the loop γ_i lifts as paths (half loops)

- $\tilde{\gamma}_i$ from \tilde{p} to \tilde{p}' ,
- $\tilde{\gamma}'_i$ from \tilde{p}' to \tilde{p} .

On the other hand, the loop γ_t lifts as loops

- $\tilde{\gamma}_t$ based at \tilde{p} ,
- $\tilde{\gamma}'_t$ based at \tilde{p}' .

Then, carefully drawing the picture, we get

$$\begin{cases} \alpha = \tilde{\gamma}_1 \cdot \tilde{\gamma}'_t \cdot \tilde{\gamma}'_\lambda, \\ \beta = \tilde{\gamma}_\lambda \cdot \tilde{\gamma}'_\infty, \\ \delta_1 = \tilde{\gamma}_t, \\ \delta_2 = \tilde{\gamma}_\infty \cdot \gamma'_t \cdot \gamma_\infty^{-1}. \end{cases}$$

We check that these loops indeed satisfy $\alpha\beta = \delta_1\beta\alpha\delta_2$ by using relations

$$\tilde{\gamma}_i \cdot \tilde{\gamma}'_i = 1 \quad \text{for } i = 0, 1, \lambda, \infty$$

and those which lift as $\gamma_0 \circ \gamma_1 \circ \gamma_t \circ \gamma_\lambda \circ \gamma_\infty = 1$, namely

$$\tilde{\gamma}_0 \circ \tilde{\gamma}'_1 \circ \tilde{\gamma}_t \circ \tilde{\gamma}_\lambda \circ \tilde{\gamma}'_\infty = 1 \quad \text{and} \quad \tilde{\gamma}'_0 \circ \tilde{\gamma}_1 \circ \tilde{\gamma}'_t \circ \tilde{\gamma}'_\lambda \circ \tilde{\gamma}_\infty = 1.$$

We get the result by projection on \mathbb{P}_x^1 . \square

Lemma 4.2. *The unique elliptic involution of X_{t_1} that permutes t_1 and t_2 acts as follows on the fundamental group:*

$$\alpha \leftrightarrow \alpha^{-1}, \quad \beta \leftrightarrow \beta^{-1}, \quad \gamma_1 \leftrightarrow \gamma_2.$$

We note that the relation $\alpha\beta = \delta_1\beta\alpha\delta_2$ is indeed invariant by the involution.

Proof. We have to take care that the base point \tilde{p} is not fixed. In fact, the involution permutes \tilde{p} and \tilde{p}' and acts on γ_i lifts as follows:

$$\tilde{\gamma}_i \leftrightarrow \tilde{\gamma}'_i \quad \text{for } i = 0, 1, t, \lambda, \infty.$$

In particular, if we denote

$$\begin{cases} \alpha' = \tilde{\gamma}'_1 \cdot \tilde{\gamma}_t \cdot \tilde{\gamma}_\lambda, \\ \beta' = \tilde{\gamma}'_\lambda \cdot \tilde{\gamma}_\infty, \end{cases}$$

then involution acts on these loops as

$$\alpha \leftrightarrow \alpha' \quad \text{and} \quad \beta \leftrightarrow \beta'.$$

We bring back these new loops to the base point \tilde{p} by conjugating (for instance) with $\tilde{\gamma}_\infty$, which gives us

$$\alpha \leftrightarrow \tilde{\gamma}_\infty \cdot \alpha' \cdot \tilde{\gamma}_\infty^{-1}, \quad \beta \leftrightarrow \tilde{\gamma}_\infty \cdot \beta^{-1} \cdot \tilde{\gamma}_\infty^{-1}, \quad \tilde{\gamma}_t \leftrightarrow \tilde{\gamma}_\infty \cdot \tilde{\gamma}'_t \cdot \tilde{\gamma}_\infty^{-1}.$$

We thus get $\delta_1 \leftrightarrow \delta_2$, and, by a direct computation, using relations between $\tilde{\gamma}_i$ and $\tilde{\gamma}'_i$, we check that $\alpha \leftrightarrow \alpha^{-1}$ and $\beta \leftrightarrow \beta^{-1}$. \square

In order to prove Theorem 2.1, it is enough to prove that the map Φ_θ is dominant, generically two-to-one. By the Riemann–Hilbert correspondance, it is equivalent to working with the corresponding spaces of monodromy representations. Let us denote by \mathcal{R}_θ the space of monodromy representations for $\mathcal{M}_{0,5}(\frac{1}{2}, \frac{1}{2}, \frac{1}{2}, \theta, \frac{1}{2})$:

$$\mathcal{R}_\theta := \left\{ (M_0, M_1, M_t, M_\lambda, M_\infty) \in \mathrm{SL}_2(\mathbb{C})^5; \begin{array}{l} M_0 M_1 M_t M_\lambda M_\infty = I \\ \mathrm{tr}(M_i) = 0 \quad \text{for } i = 0, 1, \lambda, \infty \\ \mathrm{tr}(M_t) = 2 \cos(\pi\theta) \end{array} \right\} / \sim,$$

where the equivalence relation \sim is the diagonal adjoint action by $\mathrm{SL}_2(\mathbb{C})$ on quintuples. Recall that in $\mathrm{SL}_2(\mathbb{C})$ we have

$$\mathrm{tr}(M) = 0 \Leftrightarrow M^2 = -I$$

and the corresponding $\mathrm{PSL}_2(\mathbb{C})$ -representations are actually representations

$$\Gamma \rightarrow \mathrm{PSL}_2(\mathbb{C}).$$

On the other hand, consider the space $\tilde{\mathcal{R}}_\theta$ of monodromy representations for the space $\mathcal{M}_{1,2}(\theta, \theta)$:

$$\tilde{\mathcal{R}}_\theta := \left\{ (A, B, D_1, D_2) \in \mathrm{SL}_2(\mathbb{C})^4; \begin{array}{l} AB = D_1 B A D_2 \\ \mathrm{tr}(D_1) = \mathrm{tr}(D_2) = 2 \cos(\pi\theta) \end{array} \right\} / \sim.$$

The natural map $\phi_1^*: \mathcal{R}_\theta \rightarrow \tilde{\mathcal{R}}_\theta$ induced by ϕ_1 is described by

Corollary 4.3. *We have $\phi_1^*(M_0, M_1, M_t, M_\lambda, M_\infty) = (A, B, D_1, D_2)$ with*

$$\begin{cases} A = M_1 M_t M_\lambda, \\ B = M_\lambda M_\infty, \\ D_1 = M_t, \\ D_2 = M_\infty M_t M_\infty^{-1}. \end{cases}$$

Proof. From Lemma 4.1, we know that $AB = \pm D_1 B A D_2$; we just have to check that we have the right sign, and thus a representation

$$\pi_1(X_\lambda \setminus \{t_1, t_2\}) \rightarrow \mathrm{SL}_2(\mathbb{C}),$$

and we must have $\mathrm{tr}(D_1) = \mathrm{tr}(D_2) = 2 \cos(\pi\theta)$ ($= \mathrm{tr}(M_t)$). \square

We now want to prove that the map $\phi_1^*: \mathcal{R}_\theta \rightarrow \tilde{\mathcal{R}}_\theta$ just defined is generically one-to-one. This follows from

Theorem 4.4. *Let $A, B, D_1, D_2 \in \mathrm{SL}_2(\mathbb{C})$ such that*

$$AB = D_1 B A D_2 \quad \text{and} \quad D_1, D_2 \neq \pm I.$$

Assume moreover that the subgroup $\langle A, B \rangle$ generated by A and B is irreducible, i.e. without common eigendirection. Then there is a matrix $M \in \mathrm{SL}_2(\mathbb{C})$, unique up to a sign, such that

$$MAM^{-1} = A^{-1}, \quad MBM^{-1} = B^{-1} \quad \text{and} \quad MD_1M^{-1} = D_2.$$

Moreover, $M^2 = -I$ and $(A, B, D_1, D_2) = \phi_1^(M_0, M_1, M_t, M_\lambda, M_\infty)$ for*

$$\begin{cases} M_0 = -AM, \\ M_1 = ABD_2^{-1}M, \\ M_t = D_1, \\ M_\lambda = -BM, \\ M_\infty = M. \end{cases}$$

First recall well-known results concerning $\mathrm{SL}_2(\mathbb{C})$.

Lemma 4.5. *Two matrices $A, B \in \mathrm{SL}_2(\mathbb{C})$ generate a reducible group if and only if $\mathrm{tr}[A, B] = 2$, where $[A, B] = ABA^{-1}B^{-1}$ is the commutator.*

Proof. If A and B have a common eigenvector, then we can assume $\langle A, B \rangle$ is triangular and the commutator will be a unipotent matrix, thus having trace 2. Conversely, assume that A and B have no common eigenvector. Therefore, an eigenvector v for AB will not be eigenvector for A or for B . If $ABv = \gamma v$, then in the base $(v, -\gamma Bv)$, matrices take the form

$$A = \begin{pmatrix} a & -1 \\ 1 & 0 \end{pmatrix} \quad \text{and} \quad B = \begin{pmatrix} 0 & 1/\gamma \\ -\gamma & b \end{pmatrix},$$

where $a = \text{tr}(A)$ and $b = \text{tr}(B)$. We check that

$$[A, B] = \begin{pmatrix} a^2 + b^2 + \gamma^2 - abc & \gamma^{-2}(a - b\gamma) \\ a - b\gamma^{-1} & \gamma^{-2} \end{pmatrix}$$

and thus

$$\text{tr}([A, B]) = a^2 + b^2 + c^2 - abc - 2, \quad c = \gamma + \gamma^{-1} = \text{tr}(AB).$$

Finally, these matrices A and B have a common eigenvector if, and only if,

$$a^2 + b^2 + c^2 - abc - 2 = 2. \quad \square$$

Lemma 4.6. *Let $A, B, A', B' \in \text{SL}_2(\mathbb{C})$ and assume $\text{tr}[A, B] \neq 2$. There exists $M \in \text{SL}_2(\mathbb{C})$ such that $MAM^{-1} = A'$ and $MBM^{-1} = B'$ if, and only if, $\text{tr}(A) = \text{tr}(A')$, $\text{tr}(B) = \text{tr}(B')$, $\text{tr}(AB) = \text{tr}(A'B')$.*

Proof. This is a consequence of formulae from the preceding proof. \square

Corollary 4.7. *If $\text{tr}[A, B] \neq 2$, then there exists $M \in \text{SL}_2(\mathbb{C})$, unique up to a sign, such that $MAM^{-1} = A^{-1}$ and $MBM^{-1} = B^{-1}$. Moreover, $M^2 = -I$.*

Proof. It suffices to note that $\text{tr}(A) = \text{tr}(A^{-1})$ and $\text{tr}(AB) = \text{tr}(BA)$ for all matrices $A, B \in \text{SL}_2(\mathbb{C})$. We deduce, under our assumptions, that

$$\text{tr}(A) = \text{tr}(A^{-1}), \quad \text{tr}(B) = \text{tr}(B^{-1}), \quad \text{tr}(AB) = \text{tr}(A^{-1}B^{-1}).$$

Therefore, there exists an M satisfying the first part of the statement. But M^2 has to commute to A and B . Thus M^2 must fix all eigendirections of all elements of the group $\langle A, B \rangle$. There are at least three distinct such directions and M^2 is projectively the identity: $M^2 = \pm I$. But $M = \pm I$ is impossible since $MAM^{-1} = A^{-1} \neq A$ ($A \neq \pm I$ otherwise $\langle A, B \rangle$ would be reducible). Thus $M^2 \neq I$ and $M^2 = -I$. If matrices A and B are given in the normal form as in the proof above, then M is given by

$$(5) \quad M = \pm \begin{pmatrix} \frac{\gamma^2 - 1}{2\gamma} & \frac{a - b\gamma}{2\gamma} \\ \frac{a\gamma - b}{2} & -\frac{\gamma^2 - 1}{2\gamma} \end{pmatrix}.$$

\square

Proof of Theorem 4.4. We now want to prove that the unique (up to a sign) matrix M satisfying MAM^{-1} and MBM^{-1} also satisfies $MD_1M^{-1} = D_2$, and thus $MD_2M^{-1} = D_1$ ($M^2 = -I$). From relation $AB = D_1BAD_2$, this is equivalent to

$$AB = D_1BAMD_1M^{-1} \Leftrightarrow (BAMD_1)^2 = -I \Leftrightarrow \text{tr}(BAMD_1) = 0.$$

Rewrite the relation $AB = D_1BAD_2$ into the form

$$[A, B] = D_1BAD_2A^{-1}B^{-1} = D_1D'_2 \quad \text{with } D'_2 = (BA)D_2(BA)^{-1}.$$

Note that

$$(BAM)^2 = BAMBAB = BAB^{-1}A^{-1}M^2 = -BAB^{-1}A^{-1} = -[A, B]^{-1},$$

and therefore $(BAM)^2 D_1 = -(D'_2)^{-1}$ and $\text{tr}((BAM)^2 D_1) + \text{tr}(D_1) = 0$. Now, recall that in $\text{SL}_2(\mathbb{C})$ we have universal relations

$$\text{tr}(M_1 M_2) + \text{tr}(M_1 M_2^{-1}) = \text{tr}(M_1) \cdot \text{tr}(M_2).$$

Applying this to $M_1 = BAM$ and $M_2 = BAM D_1$, we get

$$0 = \text{tr}((BAM)^2 D_1) + \text{tr}(D_1) = \text{tr}(BAM D_1) \cdot \text{tr}(BAM).$$

But $\text{tr}(BAM) \neq 0$, otherwise $(BAM)^2 = -[A, B]^{-1} = -I$, i.e. $[A, B] = I$, and that would contradict irreducibility. Thus $\text{tr}(BAM D_1) = 0$, which is what we wanted to prove. Finally, we easily check that matrices M_i given by the statement are indeed inverting preceding formulae of Lemma 4.3 by using relation $AB = D_1 B A D_2$ and properties of M . \square

5. BIELLIPTIC COVERS

Let us now assume $\theta = 0$ and rewrite

$$\tilde{\mathcal{R}}_{1/2} := \left\{ (A, B, C_1, C_2) \in \text{SL}_2(\mathbb{C})^4; \begin{array}{l} [A, B] = C_1 C_2 \\ \text{tr}(C_1) = \text{tr}(C_2) = 0 \end{array} \right\} / \sim,$$

where we have modified generators of the fundamental group for convenience:

$$C_1 = D_1 \quad \text{and} \quad C_2 = (BA)^{-1} D_2 (BA).$$

This is the monodromy space of those connections on the elliptic curve X_λ having logarithmic poles with exponent $1/2$ at t_1 and t_2 . Let us now consider the 2-fold ramified cover $\pi: \tilde{X}_{t,\lambda} \rightarrow X_\lambda$ ramifying over t_1 and t_2 and let us study the associated map

$$\pi^*: \mathcal{M}_{1,2} \left(\frac{1}{2}, \frac{1}{2} \right) \rightarrow \mathcal{M}_{2,0}$$

on the monodromy side of the Riemann–Hilbert correspondence. Denote by

$$\mathcal{R}' := \left\{ (A_1, B_1, A_2, B_2) \in \text{SL}_2(\mathbb{C})^4; [A_1, B_1][A_2, B_2] = I \right\} / \sim$$

the space of monodromy representations associated to $\mathcal{M}_{2,0}$. Then we get a map $\pi^*: \tilde{\mathcal{R}}_{1/2} \rightarrow \mathcal{R}'$ which is given by the following lemma (see also [18]).

Lemma 5.1. *We have $\pi^*(A, B, C_1, C_2) = (A_1, B_1, A_2, B_2)$ with*

$$\begin{cases} A_1 = A, \\ B_1 = B, \\ A_2 = C_1^{-1} A C_1, \\ B_2 = C_1^{-1} B C_1. \end{cases}$$

Conversely, we can characterize the image of π^* as follows.

Theorem 5.2. *Let $A_1, B_1, A_2, B_2 \in \text{SL}_2(\mathbb{C})$ such that*

$$[A_1, B_1][A_2, B_2] = I.$$

Assume that there exists a matrix $M \in \text{SL}_2(\mathbb{C})$ such that

$$MA_1 M^{-1} = A_2, \quad MB_1 M^{-1} = B_2, \quad M^2 = -I.$$

Then $(A_1, B_1, A_2, B_2) = \pi^(A, B, C_1, C_2)$ for*

$$\begin{cases} A = A_1, \\ B = B_1, \\ C_1 = M, \\ C_2 = M^{-1}[A_1, B_1]. \end{cases}$$

If moreover $\text{tr}[A_1, B_1] \neq 2$, then (A_1, B_1, A_2, B_2) is in the image of $\pi \circ \phi$, i.e. it comes from a representation of the 5-punctured sphere.

Remark 5.3. From Lemma 4.6, we see that the existence of M is almost equivalent to $\text{tr}(A_1) = \text{tr}(A_2) =: a$ and $\text{tr}(B_1) = \text{tr}(B_2) =: b$. To apply the lemma, we just need to prove that the two traces $c_i := A_i B_i$ coincide for $i = 1, 2$. But the relation $[A_1, B_1][A_2, B_2] = I$ implies that the two commutators are inverse to each other and thus share the same trace. By the commutator trace formula in the proof of Lemma 4.5, we get $(c_1 - c_2)(c_1 + c_2 - ab) = 0$. The image of π^* has codimension 2 in \mathcal{R}' . We also see that generic fibers of π^* consist of 2 points.

Remark 5.4. If we fix A_1 and B_1 generic, we obtain:

- (1) the set $\{M \in \text{SL}_2(\mathbb{C}); M^2 = -I \text{ and } M \text{ conjugates } [A_1, B_1] \text{ to its inverse}\}$ has dimension 1,
 - (2) the set $\{A_1, B_1, M^{-1} \cdot A_1 \cdot M, M^{-1} \cdot B_1 \cdot M\}$ also has dimension 1 up to conjugacy.
- Thus we can freely choose (A_1, B_1) in the image of π^* .
