## DIAGONALIZABLE NORMAL OPERATORS

## J. P. WILLIAMS<sup>1</sup>

ABSTRACT. If the image  $\varphi(A)$  of a normal operator A on a separable Hilbert space  $\Re$  is a diagonal operator for some nonzero representation  $\varphi$  of  $B(\Re)$  (that annihilates the compact operators), then A must itself be a diagonal operator on  $\Re$  (with countable spectrum). This yields an "algebraic" characterization of the closure of the range of a derivation induced by a diagonal operator.

1. Introduction. If A is a bounded normal operator on a separable Hilbert space  $\Re$  can one find a faithful  $C^*$ -representation  $\varphi$  of the full algebra  $\Re(\Re)$  of all bounded linear operators on  $\Re$  such that the eigenvectors of  $\varphi(A)$  span the representation space  $\Re_{\varphi}$ , that is, such that  $\varphi(A)$  is a diagonal operator on  $\Re_{\varphi}$ ? The question was raised by B. E. Johnson in connection with some work on derivations [4]. Our purpose here is to supply the answer: only if A is already a diagonal operator on  $\Re$ . We show also that  $\varphi(A)$  is a diagonal operator for a nonzero representation  $\varphi$  of  $\Re(\Re)$  that annihilates the compact operators if and only if A is a diagonal operator with countable spectrum.

The nondiagonalizability result as just stated hardly seems surprising. But it is interesting to note that the proof seems to require a deep result only recently discovered. Moreover, Johnson's question is reasonable because an affirmative answer would provide a satisfying result about derivations, or better, because Berberian [1] has shown that one *can* find a faithful representation  $\varphi$  of  $\mathfrak{B}(\mathfrak{K})$  such that each point of the spectrum of  $\varphi(A)$  is an eigenvalue.

2. **Diagonalizability.** For  $A \in \mathfrak{B}(\mathfrak{K})$  we shall denote by  $\delta_A$  the inner derivation  $X \to AX - XA$  on  $\mathfrak{B}(\mathfrak{K})$  and by  $\mathfrak{K}$  the ideal of compact operators on  $\mathfrak{K}$ .

Theorem 1. Let A be a normal operator on a separable Hilbert space  $\mathfrak{K}$ . The following conditions are equivalent:

- (1) There exists a nonzero representation  $\varphi$  of  $\mathfrak{B}(\mathfrak{K})$  on a Hilbert space  $\mathfrak{K}_{\varphi}$  (not necessarily faithful) such that  $\varphi(A)$  is a diagonal operator on  $\mathfrak{K}_{\varpi}$ .
  - (2) A is a diagonal operator on  $\mathfrak{R}$ .
- (3) Each positive operator in the norm closure  $\Re(\delta_A)^-$  of the range of  $\delta_A$  is compact.
  - (4) Each projection in  $\Re(\delta_A)^-$  has finite rank.

PROOF. The implications  $(2) \Rightarrow (1)$  and  $(3) \Rightarrow (4)$  are trivial. Suppose (1)

holds so that  $\varphi(A)e_i = \lambda_i e_i$  for some orthonormal basis  $\{e_i\}$  of  $\mathcal{K}_{\varphi}$ , and let  $Z = \lim \delta_A(X_n)$  be a positive operator in  $\Re(\delta_A)^-$ . Then

$$(\varphi(Z)e_i, e_i) = \lim[(\varphi(A)\varphi(X_n)e_i, e_i) - (\varphi(X_n)\varphi(A)e_i, e_i)]$$
  
= 
$$\lim[\lambda_i(\varphi(X_n)e_i, e_i) - \lambda_i(\varphi(X_n)e_i, e_i)] = 0.$$

Hence  $\sqrt{\varphi(Z)}e_i = 0$  for each i so that  $\varphi(Z) = 0$ . Thus  $Z \in \ker(\varphi) \subset \mathcal{K}$  because  $\mathcal{K}$  is separable. Thus  $(1) \Rightarrow (3)$ .

We complete the proof by showing  $(4) \Rightarrow (2)$ , or what is the same, that if A is not a diagonal operator then  $\Re(\delta_A)^-$  contains an infinite rank projection. By replacing A with its restriction to the orthocomplement of the span of its eigenvectors, there is no loss of generality in assuming that A itself has no eigenvectors.

Let B be the direct sum of countably many copies of A acting in the usual way on the space  $\widetilde{\mathbb{X}} = \mathbb{X} \oplus \mathbb{X} \oplus \mathbb{X} \oplus \cdots$ . Then by a theorem of I. D. Berg [2] there is a unitary transformation U mapping  $\mathbb{X}$  onto  $\widetilde{\mathbb{X}}$  and a compact operator K on  $\mathbb{X}$  such that  $U^{-1}BU = A + K$ .

Now A and B have no eigenvalues and consequently  $\Re(\delta_A)^-$  and  $\Re(\delta_B)^-$  respectively contain all the compact operators on  $\Re$  and  $\bar{\Re}$  respectively [6]. Hence  $\Re(\delta_A)^- = U^{-1}\Re(\delta_B)^-U$ . Also, for the same reason, if  $P_0$  is any nonzero projection of finite rank, we can choose a sequence  $X_n \in \Re(\Re)$  such that  $\|\delta_A(X_n) - P_0\| \le n^{-1}$ . Let  $\tilde{X}_n$  be the direct sum of countably many copies of  $X_n$  and let  $\tilde{P}$  be the direct sum of as many copies of  $P_0$ . Then  $\|\delta_B(\tilde{X}_n) - \tilde{P}\| \le n^{-1}$  so that  $\tilde{P} \in \Re(\delta_B)^-$ , and consequently,  $P = U^{-1}\tilde{P}U$  is a projection of infinite rank in  $\Re(\delta_A)^-$ .

3. Essential diagonalizability. A diagonal operator A on a separable space  $\Re$  has only countably many eigenvalues of course, but the spectrum itself can be any prescribed compact subset of the plane. However, if A is also diagonalizable by a representation of the Calkin algebra, there is a severe restriction on the spectrum. The first assertion of the next theorem was pointed out to me by C. Foiaş.

THEOREM 2. Let A be a normal operator on a separable Hilbert space  $\Re$ .

- (1) If  $\varphi(A)$  is a diagonal operator for some nonzero representation  $\varphi$  of  $\mathfrak{B}(\mathfrak{K})$  with  $\varphi(\mathfrak{K}) = 0$ , then the spectrum of A is countable.
- (2) Conversely, if A has countable spectrum, then  $\varphi(A)$  is a diagonal operator for any nonzero representation  $\varphi$  of  $\mathfrak{B}(\mathfrak{H})$ .

PROOF. (1) Suppose that the spectrum  $\sigma(A)$  of A is not countable. Then there is a continuous measure  $\mu$  with support contained in  $\sigma(A)$  [5, p. 176]. (For example, take  $\mu = \nu \circ f^{-1}$  where  $\nu$  is Haar measure on the compact abelian group  $G = \{0,1\}^N$  and f is a homeomorphism from G into  $\sigma(A)$ .) Let  $B_0$  be the operator defined by multiplication by the independent variable in  $L^2(\mu)$ . Then A and  $B = B_0 \oplus A$  have the same essential spectrum, so that by Berg's theorem [2] there is a unitary operator U from  $L^2(\mu) \oplus \mathcal{K}$  onto  $\mathcal{K}$  and a compact operator K with  $UBU^{-1} = A + K$ . But then  $\varphi(UBU^{-1}) = \varphi(A + K) = \varphi(A)$  is diagonal so that (Theorem 1)  $UBU^{-1}$ , and therefore B itself, is diagonal. This is a contradiction since  $B_0$  has no eigenvalues.

- (2) Suppose that A is a diagonal operator on  $\mathfrak R$  with countable spectrum and let  $\varphi$  be a nonzero representation of  $\mathfrak B(\mathfrak K)$  on a Hilbert space  $\mathfrak K_{\varphi}$ . Let  $\mathfrak R = \varphi(1)\mathfrak K_{\varphi}$ . If  $X \in \mathfrak B(\mathfrak K)$  then  $\varphi(X) = \varphi_0(X) \oplus 0$  on  $\mathfrak K_{\varphi} = \mathfrak R \oplus \mathfrak R^{\perp}$  so that  $\varphi_0$  is a representation of  $\mathfrak B(\mathfrak K)$  on  $\mathfrak R$  and  $\varphi_0(1)$  is the identity operator on  $\mathfrak R$ . In particular, the operator  $\varphi_0(A)$  has spectrum contained in  $\sigma(A)$  and is therefore countable. It suffices to show, therefore, that a normal operator B on a Hilbert space  $\mathfrak R$  having countable spectrum is diagonal. This fact is well known: if  $\mathfrak R_0$  is the span of the eigenvectors of B then  $\mathfrak R_1 = \mathfrak R \oplus \mathfrak R_0$  reduces to 0; otherwise  $\sigma(B|\mathfrak R_1)$ , being countable, must have an isolated point and this is necessarily an eigenvalue of B.
- REMARK 1. L. G. Brown has observed that Theorem 2 is valid as stated with the weaker hypothesis that the operator A is essentially normal, i.e., that  $\pi(A) = A + \Re$  is a normal element of the quotient  $\Re(\Re)/\Re$ : if  $\sigma(A)$  is uncountable choose a normal operator  $B_0$  with no eigenvalues such that  $\sigma(B_0) \subset \sigma(A)$  and let  $B = A \oplus B_0 \oplus B_0 \oplus \cdots$ . Then  $\Re(\delta_B)$  contains a projection of infinite rank so that  $\varphi(B)$  is not a diagonal operator for any nonzero representation  $\varphi$  of  $\Re(\Re)$ . Hence if  $\varphi(\Re) = 0$  then  $\varphi(A)$  is also not a diagonal operator because  $\pi(A)$  and  $\pi(B)$  are unitarily equivalent [3].
- 2. After this paper was completed the author discovered a preprint of John G. Aiken, An application of direct integral theory to a question of Calkin, [Notices Amer. Math. Soc. 21 (1974), A493]. Aiken constructs a diagonal operator A such that  $T_u(A)$  is not a diagonal operator for any of the "generalized limit" representations  $T_u$  of  $\mathfrak{B}(\mathfrak{K})/\mathfrak{K}$  introduced by J. W. Calkin, thereby answering a question explicitly(!) raised in the latter's famous paper [Ann. of Math. (2) 42 (1941), 839-873. MR 3, 208].
