# THE DENSITY OF ALTERNATION POINTS
# IN RATIONAL APPROXIMATION

P. B. BORWEIN, * A. KROÓ, * R. GROTHMANN * AND E. B. SAFF **

(Communicated by Irwin Kra)

ABSTRACT. We investigate the behavior of the equioscillation (alternation) points for the error in best uniform rational approximation on $[-1, 1]$. In the context of the Walsh table (in which the best rational approximant with numerator degree $\leq m$, denominator degree $\leq n$, is displayed in the $n$th row and the $m$th column), we show that these points are dense in $[-1, 1]$, if one goes down the table along a ray above the main diagonal $(n = [cm], c < 1)$. A counterexample is provided showing that this may not be true for a sub-diagonal of the table. In addition, a Kadec-type result on the distribution of the equioscillation points is obtained for asymptotically horizontal paths in the Walsh table.

## 1. STATEMENT OF RESULTS

Denote by $\mathscr{R}_{m,n}$ the rational functions with numerator in $\Pi_m$, the set of algebraic real polynomials of degree at most $m$, and denominator in $\Pi_n$. Then the best approximation $r^*_{m,n} = p^*_{m,n}/q^*_{m,n}$ in $\mathscr{R}_{m,n}$ to $f \in C[-1, 1]$ with respect to the uniform norm

$$(1.1) \qquad \|g\|_{[-1,1]} := \sup\{|g(x)| : x \in [-1, 1]\}$$

is unique and is characterized by an equioscillation property [M], i.e., there are $m + n + 2 - d$ points

$$(1.2) \qquad -1 \leq x_1^{(m,n)} < \cdots < x_{m+n+2-d}^{(m,n)} \leq 1,$$

where

$$(1.3) \qquad d := d(m,n) := \min\{m - \deg p^*_{m,n}, n - \deg q^*_{m,n}\},$$

such that for a $\sigma = \pm 1$ and all $k = 1, \ldots, m + n + 2 - d$

$$(1.4) \qquad f(x_k^{(m,n)}) - r^*_{m,n}(x_k^{(m,n)}) = \sigma(-1)^k \|f - r^*_{m,n}\|_{[-1,1]}.$$

(Here and below, we assume that $p_{m,n}^*$ and $q_{m,n}^*$ do not have a common factor.)

Much is known about the behavior of alternation points for best polynomial approximation $(n = 0)$. For this case, Lorentz [L] and Kroó and Saff [KS] give examples showing that for a subsequence $\{m_k\}$ the alternation points (1.2), with $m = m_k$, $n = 0$, may avoid a subinterval of $[-1, 1]$. However, Kadec [K] proved that there is always a subsequence such that the alternation points behave like the extremal points of the Chebyshev polynomial of degree $m + 1$, that is, like $\{\cos[k\pi/(m+1)]\}_{k=0}^{m+1}$. For polynomial approximation, this implies the denseness of the alternation points in $[-1, 1]$.

For rational approximation, given $m$ and $n$, we pick any alternation set (1.2) and write

$$(1.5) \qquad \rho_{m,n}(f) := \sup_{x \in [-1,1]} \min_k |x - x_k^{(m,n)}|$$

as a measure for the density of the alternation set in $[-1, 1]$. We shall prove

**Theorem 1.1.** *Let* $n = n(m)$ *satisfy*

$$(1.6) \qquad n(m) \le n(m+1) \le n(m) + 1, \qquad n(m) \le m,$$

*for* $m = 0, 1, \ldots$. *If* $f \in C[-1, 1]$, $f \notin \mathscr{R}_{m,n(m)}, m = 0, 1, \ldots$, *then*

$$(1.7) \qquad \liminf_{m \to \infty} \left( \frac{m - n(m)}{\log m} \right) \rho_{m,n(m)}(f) < \infty.$$

The proof of Theorem 1.1 will be given in §2.

*Remark.* Theorem 1.1 applies in the case $n(m) = [cm]$ for any constant $c \le 1$, where $[\cdot]$ denotes the greatest integer function. If $c < 1$, we deduce from (1.7) that

$$(1.8) \qquad \liminf_{m \to \infty} \rho_{m,[cm]}(f) = 0,$$

which implies that the alternation points are dense in $[-1, 1]$ for such a "ray sequence" of best approximants. On the other hand, we show in Theorem 1.3 below that this density may not hold when $m/n(m) \to 1$.

Our second result is similar to Kadec's result [K] on polynomial approximation. We write for $-1 \le \alpha < \beta \le 1$ (with $x_k^{(m,n)}$ as in (1.2))

$$(1.9) \quad N_{m,n}(\alpha, \beta) := \#\{x_k^{(m,n)} : \alpha \le x_k^{(m,n)} \le \beta, \ k = 1, \ldots, m+n+2-d\}.$$

**Theorem 1.2.** *Assume, in addition to the hypotheses of Theorem 1.1, that*

$$(1.10) \qquad \lim_{m \to \infty} \frac{n(m)}{m} = 0.$$

*Then there exists a subsequence* $\Omega$ *of* $\mathbb{N}$ *such that for all* $[\alpha, \beta] \subseteq [-1, 1]$,

$$(1.11) \qquad \lim_{\substack{m \to \infty \\ m \in \Omega}} \frac{N_{m,n(m)}(\alpha, \beta)}{N_{m,n(m)}(-1, 1)} = \frac{\arccos \alpha - \arccos \beta}{\pi}.$$

Finally, we give a counterexample, which shows that Theorems 1.1 and 1.2 cannot be proved for a subdiagonal of the Walsh table. Indeed, for approximation in $\mathscr{R}_{n-1,n}$ it is possible that, for all $n$, the extremal points all reside in an arbitrarily small interval.

**Theorem 1.3.** *For every* $2 > \varepsilon > 0$*, there is a function* $f \in C[-1,1]$ *such that for each* $n = 1,2,\ldots$ *the error* $f - r^*_{n-1,n}(f)$ *has no alternation points in* $(-1+\varepsilon, 1]$*.*

The proof of Theorem 1.3 will be given in §3. The results of this paper should be compared with those of Kroó and Peherstorfer [KP] for $L_1$-approximation.

## 2. Proofs of Theorems 1.1 and 1.2

We need the following lemma, which follows easily from classical results. We include the proof for the sake of completeness.

**Lemma 2.1.** *Given* $-1 \leq \alpha < \beta \leq 1$ *and* $n \in \mathbb{N}$ *there exists a* $p_n \in \Pi_n$ *with*

$$(2.1) \qquad \|p_n\|_{[-1,\alpha]\cup[\beta,1]} < 1,$$

*and*

$$(2.2) \qquad \|p_n\|_{[\alpha,\beta]} > c_1 e^{c_2 n(\beta-\alpha)},$$

*where* $c_1, c_2 > 0$ *are constants independent of* $\alpha, \beta$ *and* $n$*.*

In (2.1) and (2.2) the norms are again the sup norms over the indicated set.

*Proof.* Let

$$(2.3) \qquad T_m(x) := \cos(m \arccos x)$$

denote the Chebyshev polynomial of degree $m$. For $m := [n/2]$, $\tau := (\beta - \alpha)/2$, set

$$(2.4) \qquad q_n(x) := \frac{1}{2} T_m\left(1 + \frac{\tau^2}{2} - \left(2 + \frac{\tau^2}{2}\right)\frac{x^2}{4}\right).$$

Since $\tau \leq 1$ and

$$(2.5) \qquad T_m(1 + \eta) \geq \tfrac{1}{2}(1 + \sqrt{2\eta})^m, \qquad \eta > 0,$$

we have for some constants $c_1, c_2 > 0$:

$$(2.6) \qquad q_n(0) = \frac{1}{2} T_m\left(1 + \frac{\tau^2}{2}\right) \geq \frac{1}{4}(1 + \tau)^m > c_1 e^{n c_2(\beta-\alpha)}.$$

For $x \in [-2, -\tau] \cup [\tau, 2]$,

$$(2.7) \qquad -1 \leq 1 + \frac{\tau^2}{2} - \left(2 + \frac{\tau^2}{2}\right)\frac{x^4}{4} < 1.$$

The lemma now follows with $p_n(x) := q_n(x - (\alpha + \beta)/2)$. $\quad\square$

*Proof of Theorem* **1.1**. Set $E_m(f) := \|f - r^*_{m,n(m)}\|_{[-1,1]}$ for $m \in \mathbb{N}$. Since $f \notin \mathscr{R}_{m,n(m)}$, we have $E_m(f) > 0$ for all $m \in \mathbb{N}$. Also, from (1.6), it follows that $E_m(f) \downarrow 0$, and so from elementary theorems about series (cf. [K])

$$(2.8) \qquad \sum_{m=0}^{\infty} \frac{E_m(f) - E_{m+1}(f)}{E_m(f) + E_{m+1}(f)} = \infty.$$

Thus there is a subsequence $\Omega$ of $\mathbb{N}$ with $E_m(f) - E_{m+1}(f) \neq 0$ and

$$(2.9) \qquad \frac{E_m(f) + E_{m+1}(f)}{E_m(f) - E_{m+1}(f)} < m^2$$

for all $m \in \Omega$.

For $m \in \Omega$, set

$$(2.10) \qquad R_m := \frac{1}{E_m(f) - E_{m+1}(f)}(r^*_{m,n(m)} - r^*_{m+1,n(m+1)}).$$

At the alternation points

$$(2.11) \qquad -1 \le x_1^{(m)} < \cdots < x_{m+n(m)+2-d(m)}^{(m)} \le 1$$

of $f - r^*_{m,n(m)}$ we have with $\sigma = \pm 1$

$$(2.12) \qquad \sigma(-1)^k R_m(x_k^{(m)}) \ge 1, \qquad k = 1, \ldots, m + n(m) + 2 - d(m).$$

Moreover, from (1.6) and (2.12) it follows that $R_m = P_m/Q_m$ with

$$(2.13) \qquad \deg P_m = m + n(m) + 1 - d(m),$$

$$(2.14) \qquad \deg Q_m \le 2n(m) + 1 - d(m).$$

Thus $R_m - q$ can have at most $m + n(m) + 1 - d(m)$ zeros, if $q \in \Pi_{m-n(m)}$. Let $c_1, c_2$ be as in Lemma 2.1. For $m \in \Omega$, let $x_m^* \in [-1, 1]$ satisfy

$$(2.15) \qquad \min_k |x_m^* - x_k^{(m)}| = \rho_{m,n(m)}(f) =: t_m.$$

If $x_m^* \in [-1, x_1^{(m)}]$, we let $p_{m-n(m)}$ be the polynomial that satisfies Lemma 2.1 with $\alpha = -1$ and $\beta = x_1^{(m)}$. From (2.12) and (2.1) it follows that $R_m \pm p_{m-n(m)}$ has $m+n(m)+1-d(m)$ zeros in $(x_1^{(m)}, 1]$ and hence is zero-free in $[-1, x_1^{(m)}]$. Thus

$$(2.16) \qquad c_1 e^{c_2 t_m(m-n(m))} \le \|R_m\|_{[-1,1]} < m^2,$$

where the last inequality follows from (2.9). If $x_m^* \in [x_{m+n(m)+2-d(m)}^{(m)}, 1]$, we use Lemma 2.1 with $\alpha = x_{m+n(m)+2-d(m)}^{(m)}$ and $\beta = 1$ and again we get (2.16). Otherwise denote the zeros of $R_m$ by $y_k^{(m)}$, where

$$(2.17) \qquad x_1^{(m)} < y_1^{(m)} < x_2^{(m)} < \cdots < y_{m+n(m)+1-d(m)}^{(m)} < x_{m+n(m)+2-d(m)}^{(m)},$$

and set $y_0^{(m)} := x_1^{(m)}, y_{m+n(m)+2-d(m)}^{(m)} := x_{m+n(m)+2-d(m)}^{(m)}$. Then $|y_k^{(m)} - y_{k+1}^{(m)}| \ge t_m$ for some $k = k^*$. As above, counting the zeros of $R_m \pm (p_{m-n(m)} - 1)/2$, where $p_{m-n(m)}$ satisfies Lemma 2.1 with $\alpha = y_{k^*}^{(m)}$ and $\beta = y_{k^*+1}^{(m)}$, yields

$$(2.18) \qquad \tfrac{1}{2}\left(c_1 e^{c_2 t_m(m-n(m))} - 1\right) < m^2.$$

By (2.16) or (2.18) we get for a constant $c_3 > 0$

$$(2.19) \qquad\qquad t_m(m - n(m)) \le c_3 \log m \,,$$

which yields (1.7).  □

*Proof of Theorem* 1.2. It suffices to prove (1.11) for the case $\alpha = -1$. In fact, it is enough to show that

$$(2.20) \qquad \limsup_{\substack{m \to \infty \\ m \in \Omega}} \frac{N_{m,n(m)}(-1,\beta)}{N_{m,n(m)}(-1,1)} \le \frac{\pi - \arccos \beta}{\pi} \,,$$

since replacing $x$ by $-x$ and $\beta$ by $-\beta$, we get the corresponding lower estimate for $\liminf$. Let $m - n(m) = s(m) + l(m)$, where $s(m)$ is to be determined later. With the notations of the previous proof, set for $m \in \Omega$,

$$(2.21) \qquad\qquad q_m(x) := \tfrac{1}{2} T_{s(m)}(x + 1 - \beta) T_{l(m)}(x) \,,$$

$$(2.22) \qquad N(m) := \#\{x \in (\beta,1] : |T_{l(m)}(x)| = 1 \,, \ |q_m(x)| > m^2\} \,,$$

where $T_k$ denotes the $k$th the Chebyshev polynomial, $\|T_k\|_{[-1,1]} = 1$. Then $R_m - q_m$ has at least $N(m) - 1$ zeros in $(\beta,1]$. Thus it can have at most $m + n(m) + 2 - d(m) - N(m)$ zeros in $[-1,\beta]$. Hence

$$(2.23) \ \limsup_{m \to \infty} \frac{N_{m,n(m)}(-1,\beta)}{N_{m,n(m)}(-1,1)} \le \limsup_{m \to \infty} \frac{m + n(m) + 2 - d(m) - N(m)}{m + n(m) + 2 - d(m)}$$

$$= 1 - \liminf_{m \to \infty} \frac{N(m)}{m} \,,$$

since between two alternation points of $R_m$ in $[-1,\beta]$ is one zero of $R_m - q_m$ and since $n(m)/m \to 0 \ (d(m) \le n(m))$. In (2.23) and the rest of the proof, all limits are for $m \in \Omega$. Now choose $s(m)$ such that

$$(2.24) \qquad\qquad \lim_{m \to \infty} \frac{s(m)}{\log m} = \infty \,, \quad \lim_{m \to \infty} \frac{l(m)}{m} = 1.$$

Then the first equation in (2.24) together with (2.5) yields

$$(2.25) \qquad \lim_{m \to \infty} (\inf\{x \in (\beta,1] : \tfrac{1}{2} T_{s(m)}(x + 1 - \beta) > m^2\}) = \beta.$$

Also, for $\beta < \widetilde{\beta} < 1$, it follows from the second equation in (2.24) that

$$(2.26) \qquad \lim_{m \to \infty} \frac{\#\{x \in (\widetilde{\beta},1] : |T_{l(m)}(x)| = 1\}}{m} = \frac{\arccos \widetilde{\beta}}{\pi}.$$

Finally, (2.25) and (2.26) yield (with (2.21) and (2.22))

$$(2.27) \qquad\qquad \liminf_{m \to \infty} \frac{N(m)}{m} \ge \frac{\arccos \beta}{\pi} \,,$$

which together with (2.23) gives (2.20).  □

## 3. PROOF OF THEOREM 1.3

For $\alpha_1 \leq \cdots \leq \alpha_n < 0$ we denote by $V_{n-1}(\alpha_1, \ldots, \alpha_n) = x^{n-1} + \cdots$ the monic polynomial that minimizes

$$(3.1) \qquad \left\| \frac{p_{n-1}(x)}{\prod_{k=1}^n (x - \alpha_k)} \right\|_{[0,1]}$$

among all monic polynomials $p_{n-1}$ of degree $n-1$. Set

$$(3.2) \qquad r_{n-1}(\alpha_1, \ldots, \alpha_n)(x) := \frac{V_{n-1}(\alpha_1, \ldots, \alpha_n)(x)}{\prod_{k=1}^n (x - \alpha_k)}.$$

Then from the Haar condition (cf. [M, §3.2]), $r_{n-1}(\alpha_1, \ldots, \alpha_n)$ is uniquely determined and equioscillates $n$ times in $[0, 1]$. Moreover, these $n$ equioscillation points are the only extremal points of $r_{n-1}(\alpha_1, \ldots, \alpha_n)$ in $[0, 1]$, since $r_{n-1}(\alpha_1, \ldots, \alpha_n) - c$ can have at most $n$ zeros for each $c \in \mathbf{R}$ and since $r_{n-1}(\alpha_1, \ldots, \alpha_n)$ has all its $n-1$ zeros in $[0, 1]$. Also, zero must be one of the equioscillation points, since $|r_{n-1}(\alpha_1, \ldots, \alpha_n)(x)|$ decreases between $\alpha_n$ and the first zero of $r_{n-1}(\alpha_1, \ldots, \alpha_n)$.

We need the following lemmas.

**Lemma 3.1.** *Let* $\alpha_1 \leq \cdots \leq \alpha_n < 0$ *and* $\beta_1 \leq \cdots \leq \beta_n < 0$ *satisfy* $\alpha_k \leq \beta_k$ *for* $k = 1, \ldots, n$. *Then the equioscillation points* $x_1 < \cdots < x_n$ *of* $r_{n-1}(\alpha_1, \ldots, \alpha_n)$ *and* $y_1 < \cdots < y_n$ *of* $r_{n-1}(\beta_1, \ldots, \beta_n)$ *satisfy* $x_k \geq y_k$ *for* $k = 1, \ldots, n$.

*Proof.* It suffices to prove the lemma in the case $\alpha_k = \beta_k$ for $k \neq k^*$, $\alpha_{k^*} < \beta_{k^*}$, since we can transfer $\alpha_n$ to $\beta_n, \ldots, \alpha_1$ to $\beta_1$ successively. Define

$$(3.3) \qquad C_\alpha := 1 / \| r_{n-1}(\underline{\alpha}) \|_{[0,1]},$$

$$(3.4) \qquad C_\beta := 1 / \| r_{n-1}(\underline{\beta}) \|_{[0,1]},$$

where $\underline{\alpha} = (\alpha_1, \ldots, \alpha_n)$, $\underline{\beta} = (\beta_1, \ldots, \beta_n)$, and set

$$(3.5) \qquad \begin{aligned} q(x) &:= C_\alpha (x - \beta_{k^*}) V_{n-1}(\underline{\alpha})(x) - C_\beta (x - \alpha_{k^*}) V_{n-1}(\underline{\beta})(x) \\ &= (C_\alpha r_{n-1}(\underline{\alpha})(x) - C_\beta r_{n-1}(\underline{\beta})(x))(x - \alpha_{k^*})(x - \beta_{k^*}) \prod_{k \neq k^*} (x - \alpha_k). \end{aligned}$$

By the equioscillation, we have $(y_1 = 0)$

$$(3.6) \qquad q(y_n) \leq 0, q(y_{n-1}) \geq 0, \ldots, q(0) = 0.$$

It is easy to see that $C_\alpha > C_\beta$. Thus there is a point $x > y_n$ with $q(x) > 0$. For the (necessarily real) zeros $\xi_1 \leq \cdots \leq \xi_n$ of $q$ (some zeros may be counted twice), this implies $\xi_k \geq y_k$ for $k = 1, \ldots, n$. We also have $(x_1 = 0)$

$$(3.7) \qquad q(x_n) \geq 0, q(x_{n-1}) \leq 0, \ldots, q(0) = 0.$$

For every $\varepsilon > 0$, there is a polynomial $\tilde{q} \in \Pi_n$ with highest coefficient $C_\alpha - C_\beta$ and real zeros $\tilde{\xi}_1 \leq \cdots \leq \tilde{\xi}_n$ such that

$$(3.8) \qquad \tilde{q}(x_n) > 0, \tilde{q}(x_{n-1}) < 0, \ldots, \tilde{q}(0) < 0 \qquad \text{for } n \text{ even},$$
$$\tilde{q}(0) > 0 \qquad \text{for } n \text{ odd},$$

$$(3.9) \qquad |\tilde{\xi}_k - \xi_k| < \varepsilon, \qquad k = 1, \ldots, n.$$

It follows that $\tilde{\xi}_1 < 0$ and thus $x_k > \tilde{\xi}_k$ for $k = 1, \ldots, n$. Since $\varepsilon > 0$ is arbitrary, this implies $x_k \geq \xi_k \geq y_k$ for $k = 1, \ldots, n$. $\square$

**Lemma 3.2.** *Given* $0 < \varepsilon < 1$ *there is an increasing sequence* $a_1 < a_2 < \cdots < 0$, *such that* $r_{n-1}(a_1, \ldots, a_n)$ *has no extremal points in* $(\varepsilon, 1]$ *for* $n \geq 1$.

*Proof.* Set $a_1 := -\varepsilon/4$. We will construct $a_n$ by induction such that the function

$$(3.10) \qquad f_n(x) := \frac{\prod_{k=2}^n (x + 2a_k)}{\prod_{k=1}^n (x - a_k)}$$

alternates in sign in the points

$$(3.11) \qquad 0 = \delta_{1,n} < \cdots < \delta_{n,n} < \varepsilon$$

and satisfies

$$(3.12) \qquad |f_n(\delta_{k,n})| > |f_n(x)| \qquad \text{for } k = 1, \ldots, n, \; x \in [\varepsilon, 1].$$

If we have this sequence, $r_{n-1}(a_1, \ldots, a_n)$ cannot have an alternation point in $(\varepsilon, 1]$ for $n \geq 2$, since otherwise for a suitably chosen $\gamma \in \mathbf{R}$ the function $f_n - \gamma r_{n-1}(a_1, \ldots, a_n)$ has a zero in each interval $(\delta_{k,n}, \delta_{k+1,n})$ and an additional zero in $(\delta_{n,n}, 1)$.

We observe now that $f_1(x) = 1/(x - a_1)$ is decreasing in $[0, 1]$ and satisfies (3.12) with $\delta_{1,1} = 0$. Having constructed $a_1, \ldots, a_{n-1}$, we observe that

$$(3.13) \qquad \lim_{a_n \to 0^-} \frac{x + 2a_n}{x - a_n} = 1 \text{ uniformly on } [\lambda, 1]$$

for all $\lambda > 0$. Thus, for $|a_n|$ sufficiently small, (3.12) will be satisfied for $\delta_{k,n+1} := \delta_{k-1,n}$, $k = 3, \ldots, n+1$ and for $\delta_{1,n+1} := \delta_{1,n} = 0$. Thus it remains to show the existence of $\delta_{2,n+1}$. Since $f_{n+1}(0) = -2f_n(0)$, this follows from (3.13) by choosing $|a_n|$ small enough. $\square$

*Proof of Theorem* 1.3. We will prove the theorem on the interval $[0, 1]$. Choose $a_1, a_2, \ldots$ as in Lemma 3.2 with $\varepsilon/2$ replacing $\varepsilon$. Let, for $b_k > 0$,

$$(3.14) \qquad S_n(x) := \sum_{k=1}^n \frac{b_k}{x - a_{2k}}.$$

We now use a result in [B] stating that the best approximation to $S_n$ out of $\mathcal{R}_{n-2,n-1}$ has the form

$$(3.15) \qquad r_{n-2,n-1}^*(S_n)(x) = \frac{p_{n-2}^*(x)}{\prod_{k=1}^{n-1}(x - a_{2k+1}^*)},$$

where $p_{n-2}^*$ is of degree $n-2$ and

(3.16)                $a_2 < a_3^* < a_4 < \cdots < a_{2n-1}^* < a_{2n} < 0.$

Thus, by the equioscillation property (1.4), there is a constant $c_n$ such that

(3.17)          $S_n - r_{n-2,n-1}^*(S_n) = c_n r_{2n-2}(a_2, a_3^*, a_4, \ldots, a_{2n}).$

Since $r_{2n-2}(a_1, \ldots, a_{2n-1})$ has no alternation point in $(\varepsilon/2, 1]$, Lemma 3.1 shows that $S_n - r_{n-2,n-1}^*(S_n)$ has no alternation point in $(\varepsilon/2, 1]$. We choose the $b_k$'s such that

(3.18)        the series $f(x) = \sum_{k=1}^{\infty} \frac{b_k}{x - a_{2k}}$ converges uniformly on $[0, 1]$,

and

(3.19)     $r_{n-2,n-1}^*(f)$ is close enough to $r_{n-2,n-1}^*(S_n)$ to guarantee that $f - r_{n-2,n-1}^*(f)$ has no alternation point in $(\varepsilon, 1]$.

For (3.19) we used the fact (cf. [W]) that the best approximation operator is continuous in $S_n$, since $r_{n-2,n-1}^*(S_n)$ is nondegenerate (i.e. $d = 0$ in (1.3)). □
