

## THE BAIRE CATEGORY THEOREM AND THE EVASION NUMBER

MASARU KADA

(Communicated by Carl G. Jockusch)

ABSTRACT. In this paper we prove that  $\epsilon \leq \text{cov}(\mathcal{M})$  where  $\epsilon$  is the evasion number defined by Blass. This answers negatively a question asked by Brendle and Shelah.

### 1. INTRODUCTION

Let  $\text{cov}(\mathcal{M})$  denote the smallest size of a family of meager sets whose union covers the real line. The combinatorial characterization for  $\text{cov}(\mathcal{M})$  has been studied by Miller and Bartoszyński, and the following result is established. For  $g \in \omega^\omega$ , let  $\mathcal{S}^g = \prod_{n < \omega} [\omega]^{\leq g(n)}$ . Each element of  $\mathcal{S}^g$  is called a *slalom*.

**Theorem 1.1** ([1, Lemma 2.4.2]). *The following cardinalities are the same:*

1.  $\text{cov}(\mathcal{M})$ .
2. the smallest size of  $F \subseteq \omega^\omega$  such that for every  $h \in \omega^\omega$  there exists  $f \in F$  with  $f(n) \neq h(n)$  for all but finitely many  $n < \omega$ .
3. the smallest cardinality  $\kappa$  satisfying the following: for every  $g \in \omega^\omega$  there exists  $F \subseteq \omega^\omega$  of size  $\kappa$  such that, for all  $\varphi \in \mathcal{S}^g$ , there exists  $f \in F$  with  $f(n) \notin \varphi(n)$  for all but finitely many  $n < \omega$ .  $\square$

Blass [2] introduced a combinatorial concept called ‘predicting and evading’, and using this he defined the following cardinal invariant. Let  $\mathcal{P}$  be the collection of functions  $\pi$  from  $\omega^{<\omega}$  to  $\omega$ . Here we call each such  $\pi$  a *predictor*.

**Definition 1.2** ([2]). The *evasion number*  $\epsilon$  is the smallest size of  $F \subseteq \omega^\omega$  such that, for every  $\pi \in \mathcal{P}$  and  $X \in [\omega]^\omega$ , there exists  $f \in F$  with  $f(n) \neq \pi(f \upharpoonright n)$  for infinitely many  $n \in X$ .

Brendle and Shelah [3], [4] studied the relations between  $\epsilon$  and other cardinal invariants, and asked whether  $\epsilon > \text{cov}(\mathcal{M})$  is consistent [4, Subsection 3.4]. Here we give a negative answer to this question.

## 2. THE MAIN RESULT

We introduce a different form of evasion number by modifying the original definition due to Blass.

**Definition 2.1.**  $\mathfrak{e}^*$  is the smallest size of  $F \subseteq \omega^\omega$  such that, for every  $\pi \in \mathcal{P}$  there exists  $f \in F$  with  $f(n) \neq \pi(f \upharpoonright n)$  for all but finitely many  $n < \omega$ .

Clearly  $\mathfrak{e} \leq \mathfrak{e}^*$  holds, and it is easily seen from Theorem 1.1 that  $\text{cov}(\mathcal{M}) \leq \mathfrak{e}^*$ .

We show that  $\mathfrak{e}^*$  gives another combinatorial characterization for  $\text{cov}(\mathcal{M})$ . We prove the following theorem by modifying the proof for  $\mathfrak{e} \leq \mathfrak{d}$ , which is due to Blass [2, Theorem 13].

**Theorem 2.2.**  $\mathfrak{e}^* = \text{cov}(\mathcal{M})$ .

*Proof.* For a function  $h \in \omega^{\omega \times \omega}$ , define  $x_h \in \omega^\omega$  recursively so that  $x_h(n) = h(n, 1 + \max\{x_h(i) : i < n\})$ . Next, for a predictor  $\pi \in \mathcal{P}$ , define a function  $\varphi_\pi$  from  $\omega \times \omega$  to  $[\omega]^{<\omega}$  by letting  $\varphi_\pi(n, k) = \{\pi(t) : t \in k^n\}$ . By identifying  $\omega \times \omega$  with  $\omega$ , we can regard  $\varphi_\pi$  as a slalom in  $\mathcal{S}^g$  for a suitable  $g \in \omega^\omega$  which does not depend on  $\pi$ .

Now we prove the following: for  $n < \omega$ , if  $h(n, k) \notin \varphi_\pi(n, k)$  for all  $k$ , then  $x_h(n) \neq \pi(x_h \upharpoonright n)$ . Suppose that  $h(n, k) \notin \varphi_\pi(n, k)$  for all  $k$ . Let  $k = 1 + \max\{x_h(i) : i < n\}$ . Then  $x_h \upharpoonright n \in k^n$  and hence  $\pi(x_h \upharpoonright n) \in \varphi_\pi(n, k)$ . On the other hand,  $x_h(n) = h(n, k) \notin \varphi_\pi(n, k)$ . Thus,  $x_h(n) \neq \pi(x_h \upharpoonright n)$ .

By Theorem 1.1, we can choose  $F \subseteq \omega^{\omega \times \omega}$  of size  $\text{cov}(\mathcal{M})$  so that, for each predictor  $\pi \in \mathcal{P}$ , there is  $f \in F$  with  $f(n, k) \notin \varphi_\pi(n, k)$  for all but finitely many  $(n, k) \in \omega \times \omega$ . Then the set  $\{x_f : f \in F\}$  witnesses  $\mathfrak{e}^* \leq \text{cov}(\mathcal{M})$ , and hence  $\mathfrak{e}^* = \text{cov}(\mathcal{M})$ .  $\square$

**Corollary 2.3.**  $\mathfrak{e} \leq \text{cov}(\mathcal{M})$ .  $\square$

Let  $\text{non}(\mathcal{M})$  denote the smallest size of a nonmeager set of reals. We can characterize  $\text{non}(\mathcal{M})$  in a dual fashion, using [1, Lemma 2.4.8] instead of Theorem 1.1.

**Theorem 2.4.**  $\text{non}(\mathcal{M})$  is the smallest size of  $\Pi \subseteq \mathcal{P}$  satisfying the following: for every  $f \in \omega^\omega$  there exists  $\pi \in \Pi$  such that  $f(n) = \pi(f \upharpoonright n)$  for infinitely many  $n < \omega$ .  $\square$

## 3. A REMARK ON THE EVASION IDEAL

Brendle [3, Subsection 3.5] introduced the notion of the evasion ideal, that is, the  $\sigma$ -ideal generated by the sets of the form

$$\{f \in \omega^\omega : f(n) = \pi(f \upharpoonright n) \text{ for all but finitely many } n \in X\}$$

for  $\pi \in \mathcal{P}$  and  $X \in [\omega]^\omega$ . He considered the smallest size of a subset of  $\omega^\omega$  which does not belong to this ideal.

**Definition 3.1** ([4, Definition 3.1]).  $\mathfrak{e}(\omega)$ , the uniformity of the evasion ideal, is the smallest size of  $F \subseteq \omega^\omega$  satisfying the following: for any countable family of pairs  $\{\langle \pi_i, X_i \rangle : i < \omega\} \subseteq \mathcal{P} \times [\omega]^\omega$  there is  $f \in F$  such that for each  $i < \omega$  we have  $f(n) \neq \pi_i(f \upharpoonright n)$  for infinitely many  $n \in X_i$ .

Clearly  $\mathfrak{e} \leq \mathfrak{e}(\omega)$  holds. Brendle and Shelah asked whether  $\mathfrak{e} = \mathfrak{e}(\omega)$  can be proved in ZFC, and they presented the following partial answer.

**Theorem 3.2** ([4, Theorem 3.3]).  $\mathfrak{e} \geq \min\{\mathfrak{e}(\omega), \text{cov}(\mathcal{M})\}$ . Thus either  $\mathfrak{e} < \text{cov}(\mathcal{M})$  or  $\mathfrak{e}(\omega) \leq \text{cov}(\mathcal{M})$  implies  $\mathfrak{e} = \mathfrak{e}(\omega)$ .  $\square$

We show that the latter assumption of the above theorem holds in ZFC.

**Theorem 3.3.**  $\mathfrak{e}(\omega) \leq \mathfrak{e}^*$ .

*Proof.* Fix  $F \subseteq \omega^\omega$  of size less than  $\mathfrak{e}(\omega)$  arbitrarily. Then we can choose a countable set of pairs  $\{\langle \pi_i, X_i \rangle : i < \omega\} \subseteq \mathcal{P} \times [\omega]^\omega$  so that, for every  $f \in F$ , there is  $i < \omega$  such that  $f(n) = \pi_i(f \upharpoonright n)$  for all but finitely many  $n \in X_i$ . By shrinking  $X_i$ 's if necessary, we can assume that  $X_i$ 's are pairwise disjoint. Now define  $\pi \in \mathcal{P}$  as follows: for  $t \in \omega^{<\omega}$  if  $|t| \in X_i$  for some  $i < \omega$  then  $\pi(t) = \pi_i(t)$ ; otherwise  $\pi(t)$  is arbitrary. Then for all  $f \in F$  we have  $f(n) = \pi(f \upharpoonright n)$  for infinitely many  $n < \omega$ .  $\square$

**Corollary 3.4.**  $\mathfrak{e} = \mathfrak{e}(\omega)$ .

*Proof.* By Theorems 2.2, 3.2 and 3.3.  $\square$

#### ACKNOWLEDGEMENT

I would like to thank the referee for his helpful comment, which gives another view of the main theorem I had not noticed.
