

# Revolutionizing Computing

In about 20 years, computer chips will be so small that the effects of quantum mechanics will replace the physical laws we take for granted. While today's computing is based on bits that are either 0 or 1, the basic unit in quantum computing is the quantum bit—the qubit—which can be 0 and 1 simultaneously (with a probability associated with each). In the strange world of quantum computing, complicated procedures such as factoring large numbers are done much faster because the many steps involved can be done concurrently. The ultimate goal of mathematicians, physicists, computer scientists, and engineers in the field is to create a quantum computer that could solve in seconds some problems that would take today's most powerful computers billions of years to solve.
