

DISCRETE MORSE THEORY FOR MANIFOLDS WITH BOUNDARY

BRUNO BENEDETTI

ABSTRACT. We introduce a version of discrete Morse theory specific for manifolds with boundary. The idea is to consider Morse functions for which all boundary cells are critical. We obtain “Relative Morse Inequalities” relating the homology of the manifold to the number of interior critical cells. We also derive a Ball Theorem, in analogy to Forman’s Sphere Theorem. The main corollaries of our work are:

- (1) For each $d \geq 3$ and for each $k \geq 0$, there is a PL d -sphere on which any discrete Morse function has more than k critical $(d - 1)$ -cells.
(This solves a problem by Chari.)
- (2) For fixed d and k , there are exponentially many combinatorial types of simplicial d -manifolds (counted with respect to the number of facets) that admit discrete Morse functions with at most k critical interior $(d - 1)$ -cells.
(This connects discrete Morse theory to enumerative combinatorics/discrete quantum gravity.)
- (3) The barycentric subdivision of any simplicial constructible d -ball is collapsible.
(This “almost” solves a problem by Hachimori.)
- (4) Every constructible ball collapses onto its boundary minus a facet.
(This improves a result by the author and Ziegler.)
- (5) Any 3-ball with a knotted spanning edge cannot collapse onto its boundary minus a facet.
(This strengthens a classical result by Bing and a recent result by the author and Ziegler.)

1. INTRODUCTION

Morse theory analyzes the topology of a manifold M by looking at smooth functions $f : M \rightarrow \mathbb{R}$ whose critical points are non-degenerate. This was introduced by Marston Morse in the twenties [55]; it was developed in the second half of the 20th century by Bott, Thom, Milnor, Smale, Witten, Goresky and MacPherson (among others); and it was used by Smale and Freedman to prove the Poincaré conjecture in all dimensions higher than three. Steven Smale called Morse theory “the most significant single contribution to mathematics by an American mathematician” [30, p. 21]. Many functions are Morse; in fact, any smooth function can be approximated by a Morse function. Bott weakened Morse’s original definition in order to also allow functions whose critical cells form submanifolds rather than isolated points (e.g. constant functions); see [31, pp. 159–162] and [30].

Any Morse function provides information on the homology of a manifold. For example, the number of critical points of index i is not less than the i -th Betti numbers of the manifold. These bounds are usually not sharp, but in some cases they can be made sharp using Smale’s cancellation theorem; see e.g. [31, pp. 196–199] or [11, 64, 66]. In one case Morse theory even reveals the homeomorphism type: Reeb showed that if a Morse function on a smooth manifold without boundary has only two critical points, then the manifold is a d -sphere. The Reeb theorem is a crucial ingredient in Milnor’s proof of the existence of “exotic spheres” [53] and in Smale’s proof of the generalized Poincaré conjecture [69].

The idea of duality is at the core of Morse theory. If f is a smooth Morse function on a topological manifold without boundary M , so is $-f$. The critical points of f and $-f$ are the same, except that they have complementary index. This way Poincaré duality (“the i -th and the $(d - i)$ -th Betti number of any manifold without boundary coincide”) can be seen as a corollary of Morse theory. Moving downwards along some gradient flow line of f is the same as moving upwards along some gradient flow line of $-f$.

In the nineties Forman introduced a discretized version of Morse theory, in which topological manifolds are replaced by regular CW complexes and smooth functions are replaced by special poset maps between the face poset of the complex and (\mathbb{R}, \leq) . ‘Critical points’ are just cells at which such maps are strictly increasing [26]. Moving downwards along some gradient flow line is rendered in the discrete setting by an acyclic matching of the face poset (see Figure 2). The work of Shareshian [67] yields a partial discrete analogue to Bott’s relative Morse theory: Given a discrete Morse function on a simplicial complex, the subcomplexes consisting only of critical cells can be “divided out” [67, pp. 686–687].

Via discrete Morse functions we can bound the homology of any regular CW complex [25, pp. 107–108]. The i -th Betti number of the complex never exceeds

the number of critical i -cells. As in Reeb's theorem, in one lucky case we can even tell the homeomorphism type of the complex: Triangulated d -manifolds without boundary that admit a discrete Morse function with only two critical cells are, in fact, triangulated spheres. This was first proven by Forman in [25, p. 112]; an alternative proof is given in Theorem 3.8.

Discrete Morse theory opens doors to computational geometry [24, 39, 41, 44] and to commutative algebra [3, 40, 68]. At the same time, it builds on a classical notion in combinatorial topology, the notion of *collapse* introduced by J.H.C. Whitehead in the thirties [74]. A complex C is *collapsible* if it admits a discrete Morse function with only one critical cell. All collapsible complexes are contractible, but the converse does not hold, as shown by Zeeman's dunce hat [7, 75]. All 2-balls are collapsible, but for each $d \geq 3$ some PL d -balls are not collapsible. However, Whitehead proved that every collapsible PL d -manifold is a ball [74]. Here PL stands for "piecewise-linear"; essentially, it means that the link of any face is either a ball or a sphere. Whether the PL assumption is necessary or not in Whitehead's result still represents an open problem. However, the collapsibility assumption is necessary: Newman [58] and Mazur [50] showed that the boundary of a contractible PL manifold is a homology sphere that need not be simply connected.

Within the PL framework, discrete Morse functions dualize. With any triangulation of M we can associate a "dual complex" M^* , a cell complex with the same underlying space as M . A discrete Morse function f on a PL manifold without boundary M yields a discrete Morse function $-f$ on M^* ; moreover, the critical cells of f and $-f$ are dual to one another [25, pp. 111–112].

So far so good. However, there is some bad news. An extremely common operation in combinatorial topology is to "patch" together two 3-balls by identifying a boundary disk of the first one with a boundary disk of the second one. The resulting complex is still a 3-ball. More generally, for any positive integer d one can "patch" together two d -balls alongside a $(d-1)$ -ball in their boundary; cf. [77]. Unfortunately, discrete Morse theory does not relate well to this topological operation. For example, if we patch together two collapsible 3-balls, do we get a collapsible 3-ball? As far as we know, this problem is open. The "obvious" approach, namely, to collapse the union $C = C_1 \cup C_2$ by collapsing first C_1 and then C_2 , may fail. (A collapse of C_1 may start by removing a facet of $C_1 \cap C_2$; such a collapse is disallowed by the gluing.) In particular, we do not know whether all constructible balls are collapsible or not.

Another problem is the lack of control over the homotopy type of the boundary. For example: Is the boundary of a collapsible manifold always a sphere? The answer is not known. We know that the boundary of any collapsible (or contractible) manifold has the same homology as a sphere. Also, Whitehead showed that the boundary of a PL collapsible manifold is a sphere [74]. However, not all collapsible manifolds are PL: For a 6-dimensional example, take the cone over a non-PL 5-ball.

In the present paper, we bypass these difficulties using duality. We present a version of duality for manifolds with boundary (Theorem 3.10). Let us explain the idea in the luckiest scenario, namely, when the critical cells are as few as possible. We call a manifold without boundary "*endo-collapsible*" if it admits a discrete Morse function with two critical cells. We call a manifold with boundary "*endo-collapsible*" if it admits a discrete Morse function whose critical cells are all the boundary cells plus a single interior cell. (See Section 2 for details.) It turns out

that the notion of endo-collapsibility is *selfdual* for manifolds without boundary and essentially *dual to collapsibility* for manifolds with boundary. In fact:

- A PL manifold without boundary M is endo-collapsible if and only if M^* is [25, pp. 111–112].
- If M is a PL endo-collapsible manifold with boundary, then M^* is PL collapsible. (The converse is false; cf. Corollary 4.22.)
- If M is PL collapsible, then M^* is PL endo-collapsible (Corollary 3.11).

Now, the collapsibility notion can be extended to regular CW complexes, and even further [25, pp. 136–137]. In contrast, endo-collapsibility requires the presence of a boundary, so we may define it only for pseudo-manifolds. So why bother studying endo-collapsibility rather than collapsibility? We found four concrete reasons.

- (1) Endo-collapsibility determines the topology of a manifold. By using a result of simple-connectedness (Lemma 3.7) and the Poincaré conjecture, we can prove the following statement.

Main Theorem 1 (Theorem 3.12). *All endo-collapsible manifolds with boundary are balls.*

So the dual approach pays off: Whitehead’s approach can show that collapsible manifolds with boundary are balls, but only after adding the PL assumption.

- (2) Endo-collapsibility behaves very well under patching. The union of endo-collapsible balls that intersect in a codimension-one endo-collapsible ball is again endo-collapsible. More generally, discrete Morse functions for which the whole boundary is made of critical cells “naturally add up” (see Theorem 3.18). Reflecting on the structure of the barycentric subdivision, we reach the following result.

Main Theorem 2 (Theorems 4.1 and 4.13). *All constructible manifolds with boundary are endo-collapsible balls. The barycentric subdivisions of simplicial constructible balls are collapsible.*

The final claim of Main Theorem 2 “almost” answers the open problem of whether all (simplicial) constructible d -balls are collapsible. (Now we know that a possible counterexample, if there is any, must be in the class of non-collapsible balls with collapsible subdivision.) Also, Main Theorem 2 strengthens a classical result by Zeeman (“*all constructible manifolds with boundary are balls*”). Both Zeeman’s result and the first part of Main Theorem 2 (but not Main Theorem 1) generalize to pseudo-manifolds with boundary.

- (3) For 3-balls, endo-collapsibility is an intermediate property between constructibility and collapsibility (cf. Corollary 4.22). Now, many 3-balls contain an interior edge (called “knotted spanning”) that together with some boundary path forms a knot. If the knot is the sum of $2^r + 1$ trefoils, then the r -th barycentric subdivision of the 3-ball is *not collapsible*. This surprising obstruction, discovered in the sixties by Bing [9, 29], is sharp for all r [47]. In contrast, if the knot is the sum of $2^{r-1} + 1$ trefoils, then the r -th barycentric subdivision of the 3-ball is *not constructible* [22, 34, 35]. (For $r = 1$ this bound is “off by one” [35], [Lemma 1]; we do not know whether it is sharp for some r .) Is there an analogous theorem for endo-collapsibility with an intermediate bound between $2^{r-1} + 1$ and $2^r + 1$? The answer is positive.

Main Theorem 3 (Corollary 4.20). *If the knot is the sum of 2^r trefoils, the r -th barycentric subdivision of a 3-ball with a knotted spanning edge is not endo-collapsible.*

This bound is sharp for $r = 1$ (Corollary 4.26). Therefore, it traces a concrete line of distinction between constructible, endo-collapsible and collapsible 3-balls. The barycentric subdivision of a collapsible 3-ball is always endo-collapsible (Proposition 4.23), but not always constructible (Remark 4.24).

- (4) Taking cones trivially induces collapsibility, as the cone over *any* complex is collapsible. In contrast, taking cones preserves endo-collapsibility without inducing it:

Main Theorem 4 (Theorem 4.9). *The cone over a manifold M is endo-collapsible if and only if M is endo-collapsible.*

This leads to plenty of examples of balls that are collapsible without being endo-collapsible. If we focus on discrete Morse function for which all boundary cells are critical, studying M or $v * M$ is the same. (See Theorem 4.9.)

Endo-collapsible d -balls are characterized by the fact that they collapse onto their boundary (which is a sphere) minus a facet. However, if $d \geq 4$ this complex need not be collapsible. In fact, a “badly triangulated” sphere can still be the boundary of a “nicely triangulated” ball. (See Remark 4.14.) Are there endo-collapsible d -balls that are not collapsible? We do not have any examples at the moment. We have however the following *two* hierarchies:

Main Theorem 5 (Theorem 4.34). *For d -manifolds ($d \geq 2$),*

$$\begin{aligned} \text{shellable} &\implies \text{constructible} \implies \text{endo-collapsible} \\ &\implies \begin{cases} \text{Cohen-Macaulay} \\ \text{locally constructible} \implies \text{simply connected,} \end{cases} \end{aligned}$$

and for $d \geq 3$ all of these implications are strict.

The local constructibility notion mentioned above was introduced in connection with discrete quantum gravity in [19] and later linked to combinatorial topology in [8]. For any fixed $d \geq 2$, arbitrary simplicial d -manifolds are much more than exponentially many, when counted with respect to the number of facets [4, Chapter 2]. However, there are only exponentially many different combinatorial types of locally constructible simplicial d -manifolds [4, 8, 19]. Thus we essentially control the number of endo-collapsible manifolds.

A knotted triangulation of the 3-sphere cannot be locally constructible if the knot is complicated enough [8]. In Section 3.2, we extend this result to manifolds with arbitrary discrete Morse functions, thus answering a question of Chari [15].

Main Theorem 6 (Theorem 4.18). *For each integer $d \geq 3$ and for each $m \geq 0$, there is a PL d -sphere on which any discrete Morse function has more than m critical $(d - 1)$ -cells.*

The same can be said of d -balls if we replace “critical $(d - 1)$ -cells” by “critical interior $(d - 1)$ -cells” and we restrict the conclusion to *boundary-critical* Morse functions, that is, functions for which all boundary cells are critical.

We also provide the first known exponential bound for the total number of manifolds with a given boundary-critical discrete Morse function.

Main Theorem 7 (Theorem 3.6). *Let m and d be non-negative integers. Counting with respect to the number of facets, there are (at most) exponentially many combinatorial types of simplicial d -manifolds that admit a boundary-critical Morse function f with at most m interior critical $(d - 1)$ -cells.*

An exponential lower bound can be produced easily. In fact, the d -spheres that are combinatorially equivalent to the boundary of some stacked $(d + 1)$ -polytope are already exponentially many [4, Cor. 2.1.4]. The boundary of any $(d + 1)$ -polytope admits a discrete Morse function without critical $(d - 1)$ -cells; cf. Example 4.11.

In conclusion, relative discrete Morse theory yields a nice exponential cutoff for the class of all triangulated d -manifolds, much like “bounding the genus” yields a nice exponential cutoff for the class of triangulated surfaces [1], [4, p. 7]. So, when the number of facets is sufficiently large, d -manifolds on which every discrete Morse function has a high number of critical (interior) $(d - 1)$ -cells are the rule rather than the exception.

2. BACKGROUND

2.1. Polytopal complexes. A *polytope* P is the convex hull of a finite set of points in some \mathbb{R}^k . A *face* of P is any set of the form $F = P \cap \{\mathbf{x} \in \mathbb{R}^k : \mathbf{c} \cdot \mathbf{x} = c_0\}$, provided $\mathbf{c} \cdot \mathbf{x} \leq c_0$ is a linear inequality satisfied by all points of P . The *face poset* of a polytope is the set of all its faces, partially ordered with respect to inclusion. Two polytopes are *combinatorially equivalent* if their face posets are isomorphic as posets. A *polytopal complex* is a finite, non-empty collection C of polytopes (called *cells*) in some Euclidean space \mathbb{R}^k such that (1) if σ is in C the faces of σ are also in C , (2) the intersection of any two polytopes of C is a face of both. The dimension of a cell is the dimension of its affine hull; the dimension of C is the largest dimension of a cell of C . (Sometimes the cells are called *faces*, with slight abuse of notation.) The inclusion-maximal cells are called *facets*. Polytopal complexes where all facets have the same dimension are called *pure*. The *dual graph* of a pure d -complex C is a graph whose nodes are the facets of C : Two nodes are connected by an arc if and only if the corresponding facets of C share a $(d - 1)$ -cell. A pure complex is *strongly connected* if its dual graph is connected.

A polytopal complex C is called *simplicial* (resp. *cubical*) if all of its facets are simplices (resp. cubes). By *d -complex* we mean a “ d -dimensional polytopal complex”. The *link* of a face σ in a d -complex C is a polytopal complex with face poset isomorphic to the upper ideal of the element σ in the face poset of P . We denote it by $\text{link}_C \sigma$. The *deletion* $\text{del}_C \sigma$ is the subcomplex of the polytopes disjoint from σ . The *removal* of a face σ from C yields the subcomplex $C - \sigma$ of the polytopes disjoint from the interior of σ (cf. Figure 1). The k -skeleton of a d -complex C ($k \leq d$) is the k -complex formed by all faces of C with dimension at most k . A subcomplex D of C is called *k -hamiltonian* if the k -skeleta of C and of D are the same: For example, a spanning tree is a 0-hamiltonian 1-complex. The *underlying (topological) space* $|C|$ of a complex C is the union of all its faces. A simplicial complex C is called a *triangulation* of any topological space homeomorphic to $|C|$.

2.2. (Homology) manifolds. Every triangulation C of a compact connected d -dimensional manifold with boundary satisfies the following four combinatorial conditions:

- (1) C is pure and strongly connected;
- (2) every $(d - 1)$ -cell of C lies in at most two facets of C ;

- (3) the $(d - 1)$ -cells of C that lie in exactly one facet of C form a triangulation of the boundary of $|C|$;
- (4) the link of every interior (resp. boundary) k -face has the same homology as a $(d - k - 1)$ -sphere (resp. of a $(d - k - 1)$ -ball) [56, §35].

By a *d-manifold with boundary* we mean a polytopal complex (whose underlying space is) homeomorphic to a topological compact connected d -manifold with non-empty boundary. By *d-manifold without boundary* we mean a polytopal complex homeomorphic to a topological compact connected d -manifold with empty boundary. When we do not want to specify whether the boundary is empty or not, we just write *d-manifolds*. A *d-pseudo-manifold* P is a strongly connected (pure) d -complex in which every $(d - 1)$ -cell is contained in at most two d -cells; the *boundary* of P is the subcomplex formed by all $(d - 1)$ -cells that are contained in exactly one d -cell of P . As before, by “pseudo-manifold with boundary” we always mean a pseudo-manifold with non-empty boundary. Obviously every manifold is a pseudo-manifold, and every manifold with boundary is a pseudo-manifold with boundary. The boundary of a d -manifold is either the empty set or a disjoint union of $(d - 1)$ -manifolds without boundary. In contrast, the boundary of a pseudo-manifold need not be a pseudo-manifold. A cell of a pseudo-manifold is *interior* if it does not belong to the boundary.

By a *d-sphere* (or *d-ball*) we mean a d -manifold homeomorphic to a sphere (or a ball). A *homology pseudo-sphere* is a d -pseudo-manifold with the same homology as a sphere. For example, the link of an interior vertex in a d -manifold is a homology pseudo-sphere. It is an outstanding result in algebraic topology that all manifolds with the same *homotopy* as a sphere are spheres. This was proven by Smale [69] for $d \geq 5$, by Freedman [27] for $d = 4$ and by Perelman [60, 61] for $d = 3$. In contrast, manifolds that are homology pseudo-spheres but not spheres exist in all dimensions $d \geq 3$. None of them is simply connected: Every simply connected manifold with the same homology of a sphere is a sphere [73, Corollary 7.8, p. 180]. In contrast, a manifold with the same homotopy as a ball need not be a ball: The boundary of a contractible manifold is a homology pseudo-sphere, not necessarily simply connected [58, 50, 2]. If M is a contractible d -manifold and ∂M is a $(d - 1)$ -sphere, then M is a d -ball; see e.g. [2].

2.3. PL manifolds and Poincaré–Lefschetz duality. The barycentric subdivision $\text{sd}C$ of a complex C is the simplicial complex given by all chains of faces (with respect to inclusion) of C . If σ is a face of C , we denote by $\hat{\sigma}$ the barycenter of σ and by σ^* the subcomplex of $\text{sd}C$ given by all chains of faces of C containing σ ; see Figure 1. Note that $\dim \sigma + \dim \sigma^* = \dim C$. The complex σ^* is a cone with the point $\hat{\sigma}$ as apex and thus contractible.

A manifold is *PL* if the links of its interior (resp. boundary) vertices are piecewise linearly homeomorphic to the boundary of a simplex (resp. to a simplex). In a PL manifold, the links of interior (resp. boundary) faces are PL spheres (resp. PL balls). All d -manifolds are PL if $d \leq 4$ [13, p. 10]. However, some 5-spheres and some 5-balls are not PL [20]. If a manifold H is a homology d -pseudo-sphere but not a sphere, the *double* suspension of H is a $(d + 2)$ -sphere [14] which is not PL. (The *single* suspension of H is a $(d + 1)$ -pseudo-sphere but not a manifold.) If $d \geq 5$, every PL manifold that is a homology d -pseudo-sphere but not a sphere bounds a *contractible* PL $(d + 1)$ -manifold with boundary that is not a ball [2, 62]. Every PL d -sphere bounds a *collapsible* PL $(d + 1)$ -ball [59, 74]; see below for the definition of collapsibility.

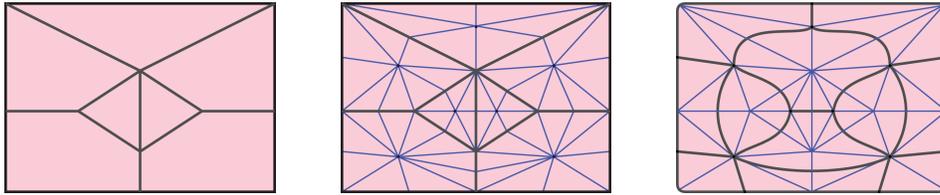

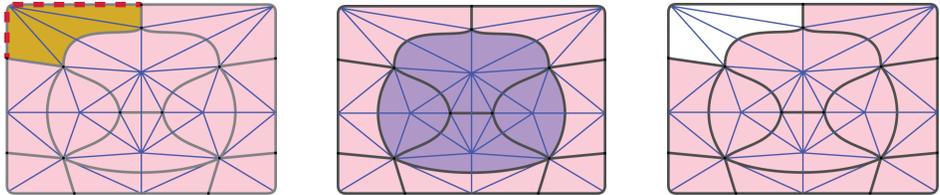

FIGURE 1. (1a): A 2-manifold with boundary M . (1b) The barycentric subdivision $\text{sd } M$. (1c) The dual block decomposition M^* . Below, (1d): The cells v^* (yellow) and v^\diamond (red, dashed), where v is the top left vertex. (1e): The complex $M^* - (\partial M)^*$ (purple). (1f): Removing the dual cell of the top-left vertex v yields the complex $M^* - v^*$. Color appears online.

Let M be a manifold without boundary. For any face σ of M , σ^* is a cone with the point $\hat{\sigma}$ as its apex and a homology pseudo-sphere as its basis. So σ^* is a contractible pseudo-manifold, or for short, a *block*. If in addition M is PL, then σ^* is a ball. The *dual block decomposition* M^* is formed by the “dual blocks” M^* of all faces of M [56, p. 377]. It is “almost” a cell complex, since these blocks need not be balls (unless M is PL). M and M^* have the same underlying space and $(M^*)^* = M$.

If M is a d -manifold with boundary, ∂M is a $(d-1)$ -manifold without boundary. If F is a k -cell of ∂M , we denote by F^* the dual of F inside M and by F^\diamond the dual of F inside ∂M . F^\diamond is a $(d-k-1)$ -dimensional block that lies in the boundary of the $(d-k)$ -dimensional block F^* ; see Figure 1. We denote by $(\partial M)^\diamond$ the dual block decomposition of ∂M with respect to itself, that is, the union of the dual blocks F^\diamond . The complex $M^* - (\partial M)^*$ is the union of all dual blocks σ^* of the interior faces σ of M . The complex M^* is instead the union of all dual blocks σ^* of the faces of M , plus $(\partial M)^\diamond$. One has $\partial(M^*) = (\partial M)^\diamond$; see Figure 1. Moreover, $M^* - (\partial M)^*$ is a deformation retract of $|M| - |\partial M|$ [56, Lemma 70.1]. Note that $M^* - (\partial M)^*$ need not be d -dimensional and need not be pure.

2.4. Regular CW complexes and (cellular) collapses. Let C be a d -complex. An *elementary collapse* is the simultaneous removal from C of a pair of faces (σ, Σ) such that σ is a proper face of Σ and of no other face of C . (σ is called a *free face* of Σ ; some complexes have no free faces.) We say C *collapses onto* D if C can be deformed onto D by a finite sequence of elementary collapses. Without loss of generality, we can always assume that the pairs $((d-1)$ -face, d -face) are removed first, all pairs of the type $((d-2)$ -face, $(d-1)$ -face) are removed immediately afterwards, and so on. A *collapsible* d -complex is a d -complex that can be collapsed onto a single vertex. Each elementary collapse is a deformation retract, so if C collapses onto D the complexes C and D are homotopy equivalent. In particular,

every collapsible complex is contractible. The converse is false; cf. [7]. However, a complex C is contractible if and only if some collapsible complex D also collapses onto C [74].

Following Hatcher [37, p. 519], we denote by \bar{e}_α^d any space homeomorphic to the closed unit ball in \mathbb{R}^d and by e_α^d the open ball obtained by removing from \bar{e}_α^d the boundary. A *CW complex* is a space constructed via the following procedure: (1) we start with a set X^0 of n points, the so-called *0-cells*; (2) recursively, we form the d -skeleton X^d by *attaching* open d -disks e_α^d (called *d-cells*) onto X^{d-1} , via maps $\varphi_\alpha : S^{d-1} \rightarrow X^{d-1}$; here “attaching” means that X^d is the quotient space of the disjoint union $X^{d-1} \sqcup_\alpha \bar{e}_\alpha^d$ under the identifications $x \equiv \varphi_\alpha(x)$, for each x in the boundary of \bar{e}_α^d ; (3) we stop the inductive process at a finite stage, setting $X = X^d$ for some d (called the *dimension* of X).

A CW complex is *regular* if the attaching maps for the cells are injective. The notion of barycentric subdivision extends to the generality of regular CW complexes: In a regular CW complex C , the chains of cells of C (with respect to inclusion) form a simplicial complex homeomorphic to C [10, p. 1861]. This is false for arbitrary CW complexes. The barycentric subdivision of any regular CW complex is a simplicial complex.

Also, the notion of collapse can be extended to regular CW complexes. Let X be a regular CW complex and Y a subcomplex of X such that X can be represented as a result of attaching a d -ball B^d to Y along one of the closed hemispheres of its boundary. The transition from X to Y is called an *elementary cellular collapse*, while the transition from Y to X is called an *elementary cellular anti-collapse*. More generally, X *cellularly collapses onto* a subspace Y if some sequence of elementary cellular collapses transforms X into Y . For details, see Kozlov [43, p. 189].

2.5. Discrete Morse theory, collapse depth, endo-collapsibility. A map $f : C \rightarrow \mathbb{R}$ on a regular CW complex C is a *discrete Morse function on C* if for each face σ :

- (i) there is at most one boundary facet ρ of σ such that $f(\rho) \geq f(\sigma)$ and
- (ii) there is at most one face τ having σ as a boundary facet such that $f(\tau) \leq f(\sigma)$.

A *critical cell* of f is a face σ of C for which:

- (i) there is no boundary facet ρ of σ such that $f(\rho) \geq f(\sigma)$ and
- (ii) there is no face τ having σ as a boundary facet such that $f(\tau) \leq f(\sigma)$.

A *collapse pair* of f is a pair of faces (σ, τ) such that:

- (i) σ is a boundary facet of τ and
- (ii) $f(\sigma) \geq f(\tau)$.

Forman [25, Section 2] showed that for each discrete Morse function f the collapse pairs of f form a partial matching of the face poset of C : The unmatched faces are precisely the critical cells of f . Each complex K endowed with a discrete Morse function is homotopy equivalent to a cell complex with exactly one k -cell for each critical simplex of dimension k [25]. For example, the complex in Figure 2 has one critical cell, which is 0-dimensional. Therefore, it is homotopy equivalent to a point.

Let M be a d -pseudo-manifold and let f be a discrete Morse function on M . Let k be an integer in $\{0, \dots, d = \dim M\}$. By $c_k(f)$ we denote the total number of critical k -cells of f ; by $c_k^{\text{int}}(f)$ we denote the number of critical k -cells of f that are not contained in the boundary of M . When there is no ambiguity, we write c_k instead of $c_k(f)$ and c_k^{int} instead of $c_k^{\text{int}}(f)$. We say that f is *boundary-critical* if all the boundary faces of M are critical cells of f . For example, the function that

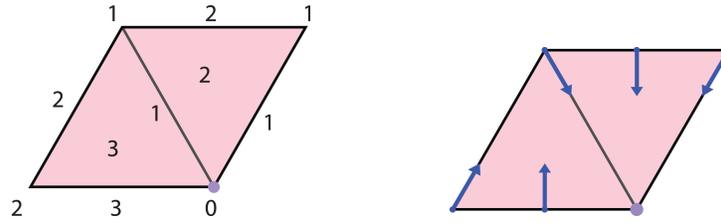

FIGURE 2. A discrete Morse function on a 2-manifold (*left*) and the collapse pairs and critical cells associated (*right*). Each pair is represented by an arrow whose tail (resp. head) is the lower-dimensional (resp. upper-dimensional) face [25]. The only critical cell in the example above is the bottom-right vertex.

assigns to each face its dimension is boundary-critical. When $\partial M = \emptyset$, any discrete Morse function is vacuously boundary-critical.

The *collapse depth* $\text{cdepth } M$ of a pseudo-manifold M is the maximal integer i such that the complex $M - \Delta$ collapses onto the union of ∂M with a $(d-i)$ -complex C , for some facet Δ of M . Equivalently, $\text{cdepth } M \geq k$ if and only if some boundary-critical discrete Morse function on M has one critical d -cell and no internal critical $(d-i)$ -cells, for each $i \in \{1, \dots, k-1\}$. By definition $\text{cdepth } M \leq \dim M$; we call a pseudo-manifold M *endo-collapsible* if $\text{cdepth } M = \dim M$.

2.6. Stanley–Reisner rings, algebraic depth, Cohen–Macaulayness. We sketch a few definitions and results, referring to Eisenbud [23] or Miller–Sturmfels [52] for details.

A *Noetherian* ring is a commutative ring all of whose ideals are finitely generated. The quotient of a Noetherian ring (modulo some ideal) is still a Noetherian ring. A *zero-divisor* is an element $x \neq 0$ such that $x \cdot y = 0$ for some $y \neq 0$. A *length- t chain* of a Noetherian ring is an increasing sequence $P_0 \subsetneq P_1 \subsetneq \dots \subsetneq P_t$ of $t+1$ prime ideals inside the ring. The *Krull dimension* of a ring is the supremum of all the chain lengths. A *length- t regular sequence* in a Noetherian ring R is a list of t elements a_1, \dots, a_t such that the ideal (a_1, \dots, a_t) does not coincide with the whole R and in addition each a_i is *not* a zero-divisor in the quotient ring $R/(a_1, \dots, a_{i-1})$. The *depth* of R is the supremum of all the lengths of its regular sequences.

The integer $\dim R - \text{depth } R$ also counts the minimal length of a finite projective resolution of R (cf. [23, pp. 474–481]). In particular, $\dim R - \text{depth } R$ is always non-negative. The rings for which $\dim R - \text{depth } R = 0$ are called *Cohen–Macaulay*. For example, the ring $\mathbb{C}[x_1, \dots, x_n]$ is Cohen–Macaulay: A length- n chain is given by $(0) \subsetneq (x_1) \subsetneq (x_1, x_2) \subsetneq \dots \subsetneq (x_1, x_2, \dots, x_n)$, while the variables x_1, \dots, x_n form a length- n regular sequence in $\mathbb{C}[x_1, \dots, x_n]$.

Let \mathbb{F} be any field. Let C be a *simplicial* complex with n vertices, labeled from 1 to n . Given a face σ of C , the monomial X_σ in the ring $\mathbb{F}[x_1, \dots, x_n]$ is the product of all variables x_i such that the vertex labeled by i is in σ . The *Stanley–Reisner ideal* of C is the monomial ideal $I_C := \{x_\sigma : \sigma \notin C\}$ generated by the “non-faces” of C . This I_C is *radical*, that is, the intersection of finitely many prime ideals. Conversely, every radical monomial ideal of $\mathbb{F}[x_1, \dots, x_n]$ is the Stanley–Reisner ideal of a unique complex on n vertices. The *Stanley–Reisner ring* $\mathbb{F}[C]$ is the quotient of $\mathbb{F}[x_1, \dots, x_n]$ by I_C . By Hilbert’s Basis Theorem [23, p. 27], every Stanley–Reisner ring is Noetherian.

The dimension of C (as a simplicial complex) is one less than the Krull dimension of $\mathbb{F}[C]$. The *algebraic depth of C over \mathbb{F}* is defined as one less than the depth of $\mathbb{F}[C]$. The simplicial complex C is called *Cohen-Macaulay over \mathbb{F}* if $\text{adepth}_{\mathbb{F}} C = \dim C$ or, equivalently, if $\text{adepth}_{\mathbb{F}} C = \text{Krull-dim } \mathbb{F}[C]$. A complex that is Cohen-Macaulay over any field is simply called *Cohen-Macaulay*. The algebraic depth of C equals the maximal integer k for which the k -skeleton of C is Cohen-Macaulay [70]. In particular, for each $d \geq 1$, a d -complex C is connected if and only if $\text{adepth}_{\mathbb{F}} C \geq 1$ for all fields \mathbb{F} . In general, $\text{adepth}_{\mathbb{F}} C$ depends on the field: For example, (any triangulation of) the projective plane is Cohen-Macaulay only over fields of characteristic $\neq 2$. The algebraic depth of C does not depend on the triangulation of C , but only on the homology of the underlying space $|C|$. By Hochster's formula and Reisner's criterion [52, p. 101],

$$\text{adepth}_{\mathbb{F}} C = \max \left\{ m : \tilde{H}_i(\text{link}_C \sigma; \mathbb{F}) = 0 \text{ for all faces } \sigma \right. \\ \left. \text{and for all integers } i < m - \dim \sigma - 1 \right\},$$

where by convention $\text{link}_C \emptyset = C$. So, a complex C is Cohen-Macaulay over \mathbb{C} if and only if $\tilde{H}_i(C) = 0$ for all $i < \dim C$ and, in addition, for each face σ of C , one has $\tilde{H}_i(\text{link}_C \sigma) = 0$ for all $i < \dim \text{link}_C \sigma$. The latter condition is automatically satisfied if C is a (homology) manifold: Hence a manifold M is Cohen-Macaulay if and only if $\tilde{H}_i(M) = 0$ for all $i < \dim M$. By [73, Corollary 7.8, p. 180] and the Poincaré conjecture, every simply connected Cohen-Macaulay d -manifold without boundary is a d -sphere.

3. MAIN RESULTS

3.1. Relative discrete Morse inequalities. Forman proved that every pseudomanifold without boundary admits a *polar* function, that is, a discrete Morse function with exactly one critical d -cell and exactly one critical 0-cell [25, pp. 110–111]. Our first lemma is a relative version of Forman's result. In analogy with Forman's *polar Morse* functions, we propose the name *equatorial Morse function* to denote a boundary-critical discrete Morse function with $c_0^{\text{int}} = 0$ and $c_d^{\text{int}} = 1$.

Lemma 3.1 (Existence of a boundary-critical Morse function). *Each d -pseudomanifold with boundary ($d \geq 2$) admits a boundary-critical discrete Morse function. Moreover, if Δ is any d -face of a d -pseudomanifold with boundary, there is an equatorial Morse function f such that Δ is the unique critical d -cell of f .*

Proof. Let M be a d -dimensional pseudomanifold with boundary. Let Δ be any facet of M . Let v be any vertex in the boundary of M . Since the dual graph of M is connected, we can choose a spanning tree T and collapse $M - \Delta$ "along T " onto the $(d - 1)$ -complex K^T of the $(d - 1)$ -faces of M not crossed by T . Since $M - \Delta$ collapses onto K^T , K^T is connected. Since T does not cross the boundary of M , the complex ∂M is completely contained in K^T . In particular, v belongs to K^T . By [25, Lemma 4.3], this already implies the existence of a boundary-critical Morse function f on M with only one critical d -cell, namely, Δ . However, a priori this f might have one or more critical interior points. Below we solve this problem by modifying f on a 0-hamiltonian 1-dimensional subcomplex of M .

Let G be the 1-complex obtained from K^T after the removal of

- (i) all critical cells σ of f with $\dim \sigma \geq 2$ and
- (ii) all collapse pairs (σ, τ) of f with $\dim \sigma \geq 1$.

G consists of the 1-skeleton of M minus all edges involved in collapse pairs of the type (edge, 2-cell), according to the function f . In particular, G contains the whole 1-skeleton of ∂M . Furthermore, G is a connected graph, because K^T is connected and both removals of types (i) and (ii) preserve connectedness. Therefore, (possibly) after removing some critical interior edges, G collapses onto the 1-skeleton of ∂M . Together with the definition of G and the fact that $M - \Delta$ collapses onto K^T , this concludes the proof. \square

From now on,

- all the discrete Morse functions on manifolds without boundary are assumed to be polar;
- all the boundary-critical discrete Morse functions on manifolds with boundary are assumed to be equatorial.

Lemma 3.2. *Let M be a manifold with boundary and let M^* be the dual block decomposition of M . Then M and the complex $M^* - (\partial M)^*$ have the same homology. If in addition M is PL, then M^* cellularly collapses onto $M^* - (\partial M)^*$.*

Proof. Form a list A_0, \dots, A_h of all the boundary faces of M , ordered by (weakly) increasing dimension. Then, remove from M^* the pairs of faces (A_i^\diamond, A_i^*) , maintaining their order. If M is PL, each of these steps removes a ball A_i^\diamond contained in the boundary of the ball A_i^* , of dimension one more. (Here we use the well-known fact that the complement of a PL d -ball in a PL d -sphere is a PL d -ball.) Therefore, each removal is an elementary cellular collapse.

If M is not PL, we can still say that M^* is obtained from $M^* - (\partial M)^*$ by attaching k -dimensional blocks A_i^* along $\partial(A_i^*) - A_i^\diamond$. Now $\partial(A_i^*)$ and ∂A_i^\diamond are homology pseudo-spheres (of dimension $k-1$ and $k-2$, respectively), while A_i^* , A_i^\diamond and $\partial(A_i^*) - A_i^\diamond$ are homologically trivial. Hence the attachment of A_i^* alongside $\partial(A_i^*) - A_i^\diamond$ does not change the homology of the space. So M^* and $M^* - (\partial M)^*$ have the same homology. \square

Theorem 3.3. *Let M be a d -manifold. Let f be a boundary-critical discrete Morse function on M .*

- (1) *M has the same homology as a cell complex with exactly c_d^{int} 0-cells, c_{d-1}^{int} 1-cells, c_{d-2}^{int} 2-cells, \dots , c_1^{int} $(d-1)$ -cells and c_0^{int} d -cells.*
- (2) *If in addition M is PL, then M is homotopy equivalent to a cell complex with c_{d-k}^{int} k -cells, for each $k = 0, \dots, d$.*

Proof. We prove the theorem only in the case where M is a d -manifold with boundary. (The case $\partial M = \emptyset$ could be shown analogously, but it was already proven by Forman [25, pp. 103–112].) We can assume that $c_d^{\text{int}} = 1$ and $c_0^{\text{int}} = 0$. Let Δ be the unique critical d -cell of f . For each $0 < k < d$, let $\sigma_1^{(k)}, \sigma_2^{(k)}, \dots, \sigma_{c_k^{\text{int}}}^{(k)}$ be the list of all interior critical k -cells of f . From f we can read a list of removals of interior faces:

- first we remove all collapse-pairs of the type $((d-1)\text{-face}, d\text{-face})$;
- then we remove the $(d-1)$ -faces $\sigma_1^{(d-1)}, \sigma_2^{(d-1)}, \dots, \sigma_{c_{d-1}^{\text{int}}}^{(d-1)}$;
- then all collapse-pairs $((d-2)\text{-face}, (d-1)\text{-face})$;

- then the $(d - 2)$ -faces $\sigma^{(d-2)}_1, \sigma^{(d-2)}_2, \dots, \sigma^{(d-2)}_{c_{d-2}^{\text{int}}}$;
- \vdots
- then all collapse-pairs (edge, 2-face);
- then the edges $\sigma^{(1)}_1, \sigma^{(1)}_2, \dots, \sigma^{(1)}_{c_1^{\text{int}}}$;
- then all collapse-pairs (vertex, edge).

At the end of this process we are left with ∂M . Let us form a dual block decomposition by dualizing the previous process. We start with $X_0 := \Delta^*$, and we progressively attach onto X_0 the dual blocks of the faces that appear in the sequence above. For example, if (σ, Σ) is the first collapse-pair removed, we set $X_1 = X_0 \cup \sigma^* \cup \Sigma^*$, and so on. There are two cases to consider:

- (I) (σ, Σ) is a collapse-pair with $\dim \sigma = s$. If M is PL, then the attachment of σ^* (which is a $(d - s)$ -ball) and Σ^* (which is a $(d - s - 1)$ -ball in the boundary of σ^*) yields a cellular anti-collapse. Cellular anti-collapses do not change the homotopy type of a space. If M is not PL, the link of σ in M might not be a sphere, thus σ^* might not be a ball. However, σ^* is a block attached alongside the codimension-one block $\partial\sigma^* - \Sigma^*$ in its boundary. By the Mayer-Vietoris theorem, the attachment of σ^* does not change the homology of the space.
- (II) σ is a critical cell. If M is PL and with $\dim \sigma = s$, then the attachment of σ^* glues a $(d - s)$ -dimensional ball along its whole boundary. If M is not PL, the attachment of the dual block of a critical cell glues a block alongside its whole boundary, which is a homology pseudo-sphere.

Eventually, the space Z obtained is the union of the dual blocks of all interior faces. In other words, $Z = M^* - (\partial M)^*$. By construction, Z has the same homology as a cell complex with exactly c_k^{int} $(d - k)$ -cells for each k . If in addition M is PL, Z is *homotopy equivalent* to a cell complex with exactly c_k^{int} cells of dimension $(d - k)$, for each k . Applying Lemma 3.2, we conclude. \square

Corollary 3.4 (Relative (weak) Morse inequalities). *Let M be any manifold. For any boundary-critical discrete Morse function f on M ,*

$$H_{d-k}(M) \leq c_k^{\text{int}}(f) \quad \text{for each } k.$$

The relative (weak) Morse inequalities boil down to the classical ones if $\partial M = \emptyset$. Unless M is PL, however, Theorem 3.3 and Corollary 3.4 yield no information on the fundamental group of M . But suppose that M is *not* PL; suppose that some boundary-critical discrete Morse function f on M has no critical interior $(d - 1)$ -cells; is M simply connected or not? We will answer this question positively in Lemma 3.7. Before proving it, however, we need a combinatorial digression.

3.2. Asymptotic enumeration of manifolds. In this section we characterize manifolds with $c^{\text{int}}(f) = m$ for some positive integer m and some boundary-critical discrete Morse function f . (See Theorem 3.5.) We also prove there are not so many, compared to the total number of manifolds: For m fixed, we give an explicit exponential upper bound in terms of the number of facets (Theorem 3.6).

By a *tree of d -polytopes* we mean a d -ball whose dual graph is a tree. Together with Ziegler [8] we showed that the number of different combinatorial types of trees of N d -simplices is bounded above by the d -th Fuss–Catalan number $C_d(N) := \frac{1}{(d-1)N+1} \binom{dN}{N}$; furthermore, this exponential upper bound is essentially

sharp. Therefore, for fixed d there are exponentially many trees of d -simplices, counting with respect to the number of facets [8].

In 1995 Durhuus and Jonsson [19] introduced the class of *LC manifolds*, defined as follows: An LC d -pseudo-manifold is a pseudo-manifold obtained from a tree of d -polytopes by repeatedly gluing together two combinatorially equivalent adjacent $(d - 1)$ -faces of the boundary. Here “adjacent” means “sharing at least a $(d - 2)$ -face” and represents a dynamic requirement: after each identification, new pairs of boundary facets that become adjacent may be glued together. (The cell complexes consecutively formed during the gluing process might not be polytopal complexes; ignore this difficulty for the moment or see [4] for details.)

The following properties follow more or less directly from the definition:

- (1) all LC manifolds (with or without boundary) are simply connected [19];
- (2) all shellable balls and spheres are LC [8];
- (3) for fixed $d \geq 2$, there are at most exponentially many combinatorial types of LC d -manifolds triangulated with N d -simplices [8].

This yields a non-trivial upper bound for the number of shellable manifolds. In contrast, for fixed $d \geq 2$ there are *more* than exponentially many d -manifolds triangulated with N d -simplices [4, pp. 45–47]. So, counting with respect to the number of facets, most of the d -manifolds are not shellable.

In 2009, the author and Ziegler [8] characterized LC 3-spheres as the 3-spheres that become collapsible after the removal of a facet. So LC 3-spheres and endo-collapsible 3-spheres are the same. The characterization was later extended to manifolds of arbitrary dimension [4]: LC d -manifolds coincide with the class of manifolds M such that for some facet Δ , $M - \Delta$ collapses onto $C \cup \partial M$, with $\dim C = d - 2$. This is a weaker notion than endo-collapsibility. Here is a reformulation in the language of discrete Morse theory (where the LC notion corresponds to the case $m = 0$):

Theorem 3.5 (cf. [4, Theorem 5.5.1]). *Let M be a d -manifold ($d \geq 2$). Let m be a non-negative integer. The following are equivalent:*

- (I) *M admits a boundary-critical discrete Morse function f , with $c_{d-1}^{\text{int}}(f) = m$.*
- (II) *M is obtained from a tree of d -polytopes P by subsequently:*
 - (a) *gluing together m pairs of combinatorially equivalent boundary faces of dimension $d - 1$ (not necessarily adjacent);*
 - (b) *then, repeatedly gluing together two combinatorially equivalent adjacent boundary faces of dimension $d - 1$.*

Proof. Let M be a d -manifold satisfying (II). Let T be the dual graph of P . Let K^T be the subcomplex of M given by all the $(d - 1)$ -faces that are not perforated by T . The tree of polytopes P can be recovered by “cutting M open” along $K^T - \partial M$. We will call *cut faces* the $(d - 1)$ -dimensional faces of K^T that do not belong to ∂M . Each cut face σ corresponds to two $(d - 1)$ -faces σ', σ'' of ∂P . (Roughly speaking, the boundary of P consists of a “single copy” of ∂M plus a “double copy” of $K^T - \partial M$.) We claim that:

- (i) for each facet Δ of M , the d -complex $M - \Delta$ collapses onto the $(d - 1)$ -complex K^T ;
- (ii) from phase (IIa) we can read a removal of m cut faces from K^T , yielding a $(d - 1)$ -complex K' that still contains ∂M ;

- (iii) from phase (IIb) we can read a sequence of elementary collapses on K' that removes all the remaining cut faces, thus yielding a $(d-1)$ -complex K'' that contains ∂M and has no $(d-1)$ -face in $M - \partial M$.

From this claim condition (I) follows immediately. So all we need to show is the validity of the claim. Item (i) follows directly from the definition of K^T : Just collapse $M - \Delta$ along T . Item (ii) can be shown step by step: The identification of two cut faces σ' and σ'' in phase (IIa) corresponds to the removal of (the interior of) σ from K^T . As for item (iii), gluing together *adjacent* $(d-1)$ -faces σ' and σ'' which share a $(d-2)$ -face F corresponds to sinking F into the interior. We can associate to this step the elementary collapse that removes σ together with its free face F from the complex.

Conversely, suppose (I) holds: Let us show (II). By Lemma 3.1, we can assume that f is equatorial, resp. polar, according to whether M is a manifold with boundary, resp. without boundary. For some facet Δ of M we have:

- (A) a list of elementary collapses of the type $((d-1)$ -face, d -face) which transforms $M - \Delta$ into some $(d-1)$ -complex K containing ∂M ;
- (B) a list of exactly m $(d-1)$ -faces in the interior of M whose removals transform K onto some $(d-1)$ -complex K' that still contains ∂M ;
- (C) a list of elementary collapses of the type $((d-2)$ -face, $(d-1)$ -face) which collapses K' onto some $(d-1)$ -complex, all of whose $(d-1)$ -faces are in ∂M , such that K' contains ∂M .

The sequence of collapses (A) acts along some spanning tree T of the dual graph of M . Thus K is the complex of the $(d-1)$ -faces of M not hit by T . This T (or equivalently K) uniquely determines a tree of polytopes P “inside M ”. (The dual graph of P is T ; P can also be obtained by cutting M open alongside $K - \partial M$.) We are going to show how to obtain M from P via gluings of adjacent boundary facets.

Let us label by b_1, b_2, \dots, b_m (maintaining their order) the facets of K that appear in the list (B). Since each facet of K corresponds to two facets of ∂P , we label by b'_i and b''_i the two boundary facets of P corresponding to b_i . We start with the tree of polytope P and perform the gluings $b'_i \equiv b''_i$, for $i = 1, \dots, m$. A priori, there are several ways to identify two $(d-1)$ -faces. However, we should glue together $b'_i \equiv b''_i$ exactly in the way they are identified inside M .

Let us label by $1, 2, \dots, t$ (maintaining their order) the facets of K' that appear in the list (C). Any of these faces (say, the one labeled by i) corresponds to *two* facets of ∂P , which we label by i' and i'' . We now perform the gluings $i' \equiv i''$, for $i = 1, \dots, t$. It is not difficult to check that either i' and i'' are adjacent or that (recursively) they have become adjacent after we glued together some j' and j'' , with $j < i$. The crucial idea is that i' and i'' always share at least the $(d-1)$ -face F_i that is removed together with i in the i -th elementary collapse of the list (C). Eventually, we re-obtain the starting manifold M . \square

Based on Theorem 3.5, we now proceed to bound from above the number of combinatorial types of simplicial manifolds with $c_{d-1}^{\text{int}}(f) = m$ for some f . The following theorem extends results by Durhuus and Jonsson [19, Theorem 1] and by the author and Ziegler [8, Theorem 4.4]. The idea, however, is analogous. We have to count certain simplicial manifolds, which are obtained from some tree of N d -simplices by performing matchings in the boundary. The crucial point is that the matchings are not arbitrary: Only two particular types of matchings are allowed.

Now, there are exponentially many combinatorial types of trees of N d -simplices [8]. Choose one. How many different manifolds can we obtain from it by performing some sequence of matchings of the prescribed type?

Theorem 3.6. *Let m and d be positive integers. There are at most*

$$(de)^N 2^{d(d-1)N} \cdot (dN - N + 2)^{2m} \cdot m! \left(\frac{2^d e^2 d!}{2m^2} \right)^m 4^d$$

combinatorial types of simplicial d -manifolds with N facets that admit a boundary-critical Morse function f with exactly m critical $(d-1)$ -cells in the interior. For fixed m and d , the previous bound is singly exponential in N .

Proof. By Theorem 3.5, a d -manifold M that admits a map f as above is obtainable from a tree of d -simplices by performing matchings of type (IIa) or (IIb). As shown in [8, Section 4], the number of distinct trees of N d -simplices is bounded above by $(de)^N$. Set $D := \frac{1}{2}(dN - N + 2)$. A tree of N d -simplices has exactly $2D$ boundary facets of dimension $d-1$. Let us bound the number of matchings described as “of type (IIa)” in Theorem 3.5. There are:

- $\binom{2D}{2m}$ ways to choose $2m$ facets out of $2D$,
- $(2m)!! = 2m(2m-2)\dots 2 = 2^m m!$ ways to match them, and
- $(d!)^m$ ways to glue them together. In fact, a $(d-1)$ -simplex has d vertices, so a priori there are $d!$ ways to identify two $(d-1)$ -simplices.

So, the total number of simplicial pseudo-manifolds with N facets that can be obtained from a tree of simplices via m matchings of type (IIa) is at most

$$(de)^N \binom{2D}{2m} 2^m m! \cdot (d!)^m.$$

If we apply the inequality $\binom{a}{b} < a^b b^{-b} e^b$, the bound simplifies into

$$(1) \quad (de)^N (2D)^{2m} m! \left(\frac{e^2 d!}{2m^2} \right)^m.$$

We still have to bound the number of matchings described as “type (IIb)” in Theorem 3.5. A tree of N d -simplices has exactly dD pairs of adjacent boundary facets. (In fact, the boundary has exactly dD faces of dimension $d-2$.) Each matching of type (IIa) creates (at most) d new pairs of adjacent faces. So, before we start with type (IIb) gluings, we have a simplicial d -pseudo-manifold P with at most $dD + dm$ pairs of adjacent $(d-1)$ -cells in the boundary and with exactly $2D - 2m$ boundary facets. Proceeding as in [19, Theorem 1] or [8, Section 4], we organize the gluings into rounds. The first round will contain couples that are adjacent in ∂P . Recursively, the $(i+1)$ -th round will consist of all pairs of facets that become adjacent only after a pair of facets are glued together in the i -th round. So, the first round of identifications consists in choosing n_1 pairs out of $dD + dm$. After each identification at most $d-1$ new ridges are created, so that when the first round is over there are at most $(d-1)n_1$ new pairs. The second round consists in choosing n_2 pairs out of these $(d-1)n_1$, and so on. Eventually, we recover the starting manifold M . Since we are performing a (partial) matching of the $2D - 2m$ boundary facets of P , $n_1 + \dots + n_f \leq D - m$. In particular, since the n_i 's are positive integers, there can be at most $D - m$ rounds. This way we obtain the

upper bound

$$\sum_{f=1}^{D-m} \sum_{\substack{n_1, \dots, n_f \in \mathbb{Z}_{>0} \\ \sum n_i \leq D-m \\ n_{i+1} \leq (d-1)n_i}} \binom{dD+dm}{n_1} \binom{(d-1)n_1}{n_2} \cdots \binom{(d-1)n_{f-1}}{n_f}$$

for type (IIb) matchings. Let us apply the inequality $\binom{a}{b} < 2^a$ everywhere, while ignoring the conditions $n_{i+1} \leq (d-1)n_i$. This way we reach the weaker bound

$$(2) \quad \sum_{f=1}^{D-m} \sum_{\substack{n_1, \dots, n_f \in \mathbb{Z}_{>0} \\ \sum n_i \leq D-m}} 2^{dD+dm} 2^{(d-1)(D-m)}.$$

There are $\binom{D-m-1}{f-1}$ f -ples of positive integers whose sum is exactly $D-m$. Also, choosing f positive integers that add up to less than $D-m$ is the same as choosing $f+1$ positive integers that add up to $D-m$. So there are $\binom{D-m-1}{f}$ f -ples of positive integers whose sum is less than $D-m$. Thus

$$\begin{aligned} \sum_{f=1}^{D-m} \sum_{\substack{n_1, \dots, n_f \in \mathbb{Z}_{>0} \\ \sum n_i \leq D-m}} 1 &= \sum_{f=1}^{D-m} \binom{D-m-1}{f-1} + \binom{D-m-1}{f} \\ &= \sum_{f=1}^{D-m} \binom{D-m}{f} = 2^{D-m} - 1. \end{aligned}$$

So, bound (2) boils down to $2^{Dd+dm+(d-1)(D-m)+D-m} = 2^{2Dd}$. Multiplying it with bound (1) we obtain the final bound

$$(de)^N (2D)^{2m} m! \left(\frac{e^2 d!}{2m^2} \right)^m 2^{2Dd}$$

for the total number of simplicial manifolds with $c_{d-1}^{\text{int}}(f) = m$ for some boundary-critical Morse function f . The conclusion follows by replacing $2D$ with $dN - N + 2$. \square

3.3. Sphere and Ball Theorems. In this section we show that endo-collapsible manifolds are either spheres or balls (Theorem 3.12). We also give a version of the duality of Morse functions for manifolds with boundary (Theorem 3.10). Given a pair (M, L) of the type (PL manifold, subcomplex), we show that any boundary-critical discrete Morse function on M yields bounds for the homotopy of the complement of L in M (Theorem 3.15).

In Section 3.2 we characterized the manifolds that admit discrete Morse functions f with $c_d^{\text{int}}(f) = 1$ and $c_{d-1}^{\text{int}}(f) = m$. This allows us to obtain the following crucial result:

Lemma 3.7. *Let M be a d -manifold, $d \geq 2$. Suppose there is a boundary-critical discrete Morse function f on M such that $c_d^{\text{int}} = 1$ and $c_{d-1}^{\text{int}} = 0$. Then, M is simply connected.*

Proof. In view of Theorem 3.5, a manifold M that admits a discrete Morse function with $c_d^{\text{int}} = 1$ and $c_{d-1}^{\text{int}} = 0$ is obtainable from a tree of d -polytopes by repeatedly identifying two adjacent boundary facets. Now, a tree of d -polytopes is obviously

simply connected. (It is a d -ball.) Moreover, if we identify boundary facets that share (at least) a $(d - 2)$ -face, we do not create any new loop when $d \geq 2$. By induction on the number of identifications, we conclude that M is simply connected. \square

As an application, we obtain an alternative proof of Forman's Sphere Theorem.

Theorem 3.8 (Forman [25, p. 112]). *Let $d \geq 2$ be an integer. Let M be a d -manifold without boundary with a Morse function f with exactly two critical cells. Then M is a d -sphere.*

Proof. The two critical cells have to be a 0-cell v and a d -cell Δ [25]. From the (relative) Morse inequalities (Corollary 3.4) we obtain that $\tilde{H}_i(M) = 0$ for all $i < \dim M$. By Lemma 3.7, M is simply connected. In particular, $\tilde{H}_d(M) = \mathbb{Z}$. All simply connected homology spheres are homotopy spheres and thus spheres, by the d -dimensional Poincaré conjecture. \square

Remark 3.9. Forman's original proof [25, p. 112] uses the d -dimensional Poincaré conjecture, with the alternative of a direct combinatorial argument when $d = 3$, using Whitehead's result that PL collapsible manifolds are balls. Here is another direct combinatorial approach: In view of Theorem 3.5, endo-collapsible manifolds are LC. In [19] Durhuus and Jonsson showed that all (simplicial) LC 3-manifolds without boundary are 3-spheres. Their proof, which is elementary, can be adapted to the non-simplicial case [4, pp. 32–34]. So, all endo-collapsible 3-manifolds without boundary are 3-spheres.

Forman [25, Theorem 4.7] observed that for each discrete Morse function f on a PL manifold *without* boundary M the function $-f$ is a discrete Morse function on the dual block decomposition M^* . Furthermore, σ is a critical cell of f if and only if σ^* is a critical cell of $-f$. We may now extend these results to manifolds *with* boundary:

Theorem 3.10 (Relative duality). *Let M be a PL manifold with boundary. Let M^* be the dual of M .*

- (1) *For each boundary-critical discrete Morse function f on M , there exists a (non-boundary-critical) discrete Morse function f^* on M^* with the following properties:*
 - *none of the boundary cells of M^* is a critical cell of f^* ;*
 - *any interior cell σ is a critical cell of f if and only if σ^* is a critical cell of f^* ;*
 - $c_{d-k}(f^*) = c_k^{\text{int}}(f)$.
- (2) *For each discrete Morse function f on M (not necessarily boundary-critical), there exists a discrete Morse function f^* on M^* with the following properties:*
 - *each of the boundary cells of M^* is a critical cell of f^* (that is, f^* is boundary-critical);*
 - *any interior cell σ is a critical cell of f if and only if σ^* is a critical cell of f^* ;*
 - $c_{d-k}(f) = c_k^{\text{int}}(f^*)$.

Proof. To prove (1) we first define a discrete Morse function g on $M^* - (\partial M)^*$ by setting

$$g(\sigma^*) = -f(\sigma) \quad \text{for all interior cells } \sigma \text{ of } M.$$

Using the fact that f is boundary-critical, it is easy to see that the critical cells of f and g are dual to each other, hence $c_{d-k}(g) = c_k^{\text{int}}(f)$. Now we use Lemma 3.2 and [25, Lemma 4.3] to argue that g can be extended to a function \tilde{g} on M^* with the same critical cells. (See Figures 3 and 4.) Thus $c_{d-k}(\tilde{g}) = c_{d-k}(g) = c_k^{\text{int}}(f)$. This \tilde{g} is the desired f^* .

To show (2), first note that the cells of M^* can be partitioned into two types: Those of the type σ^* , for some σ in M , and those of the type δ^\diamond , for some δ in ∂M . In order to make all cells of the type δ^\diamond critical, we choose a positive integer p and we define a map F_p on M^* as follows:

$$F_p(\tau) = \begin{cases} -f(\sigma) & \text{if } \tau = \sigma^* \text{ for some } \sigma \text{ in } M, \\ -p + \dim \tau & \text{if } \tau = \delta^\diamond \text{ for some } \delta \text{ in } \partial M. \end{cases}$$

Choose p large enough so that F_p is a boundary-critical discrete Morse function. (See Figures 5 and 6.) Set $f^* = F_p$. A cell of the type σ^* is critical for f^* if and only if σ in M is critical for f . On the other hand, any cell of the type δ^\diamond is critical. \square

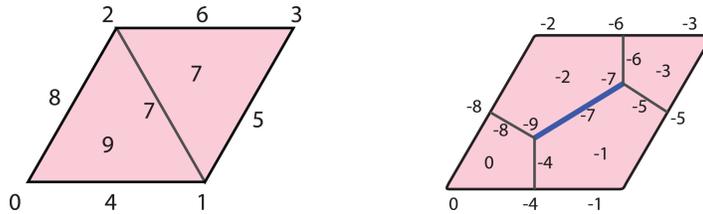

FIGURE 3. (Left) A boundary-critical discrete Morse function f on a 2-manifold M with boundary. If Δ is the left triangle, $M - \Delta$ collapses onto ∂M . (Right) A corresponding discrete Morse function f^* on M^* . The complex M^* collapses onto $M^* - (\partial M)^*$, which consists of a single edge. The edge $M^* - (\partial M)^*$ collapses onto its leftmost endpoint Δ^* .

FIGURE 4. Same as Figure 3, but this time we draw the matchings rather than the discrete Morse functions. The arrow is reversed in the dualization process.

Corollary 3.11. *Let M be a PL d -manifold with boundary.*

- (1) *If $M - \Delta$ collapses onto the boundary ∂M for some facet Δ , then M^* cellularly collapses onto the vertex Δ^* .*
- (2) *If M collapses onto a vertex v , then M^* minus the facet v^* cellularly collapses onto ∂M^\diamond .*

Proof. To show item (1), apply Theorem 3.10, part (1), to the case $c_d^{\text{int}}(f) = 1$ and $c_k^{\text{int}}(f) = 0$ for each $k < d$. This is illustrated in Figures 3 and 4 above. (Also compare Corollary 4.22.)

For item (2), apply Theorem 3.10, part (2), to the case $c_0(f) = 1$ and $c_i(f) = 0$ for each $i > 0$. This is illustrated in Figures 5 and 6. \square

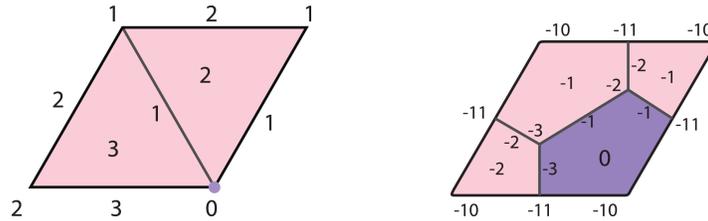

FIGURE 5. (Left) A discrete Morse function f on a 2-manifold M with boundary. M collapses onto the bottom right vertex v (in purple). (Right) A corresponding boundary-critical discrete Morse function f^* on M^* . The cell v^* is colored purple. The (pink) complex $M^* - v^*$ collapses onto the boundary of M^* . Color appears online.

FIGURE 6. Same as Figure 5, but this time we draw the matchings rather than the discrete Morse functions. Dualizing reverses the arrows: Intuitively, a collapsible complex “implodes” to a vertex (left), while an endo-collapsible complex “explodes” to its boundary after a facet is removed (right).

Theorem 3.12 (Ball Theorem). *Let M be a d -manifold with boundary (PL or non-PL). Let f be a boundary-critical Morse function on M . Suppose f has only one critical interior cell. Then:*

- (1) M is a ball;
- (2) if in addition M is PL, then the dual block decomposition M^* is cellularly collapsible.

Proof. Let Δ be the unique (d -dimensional) critical cell of f in the interior of M . Since f is boundary-critical, $M - \Delta$ collapses onto ∂M . By Lemma 3.7, M is simply connected. Using Seifert–Van Kampen and Mayer–Vietoris, we obtain that $M - \Delta$ is simply connected and has trivial homologies up to the $(d - 1)$ -st one. Since $M - \Delta$ collapses onto ∂M , the $(d - 1)$ -manifold ∂M is homotopy equivalent to $M - \Delta$. Thus ∂M is a simply-connected homology $(d - 1)$ -sphere. By [73, Corollary 7.8, p. 180] and the $(d - 1)$ -dimensional Poincaré conjecture, ∂M is a sphere. So M is a simply connected homology ball and ∂M is a sphere. Applying [73, Corollary 7.8, p. 180] and the d -dimensional Poincaré conjecture, we obtain that M is a ball. Item (2) follows from Corollary 3.11, part (1). \square

Remark 3.13. In the PL case (and in particular if $d \leq 4$), Theorem 3.12 admits a direct combinatorial proof. In fact, by Corollary 3.11, M^* cellularly collapses onto the point Δ^* , whence we conclude by using Whitehead’s theorem [74, Corollary 1, p. 293]. Compare Remark 3.9.

Conversely to the approach of Theorem 3.12 and Theorem 3.8, suppose we are given a triangulated sphere (or a triangulated ball). Can we find “perfect” (boundary-critical) discrete Morse functions on them, possibly after refining the triangulation? The following is a (partial) answer.

Definition 3.1. A PL^+ d -ball is a ball piecewise-linearly homeomorphic to a d -simplex. A PL^+ d -sphere is a sphere piecewise-linearly homeomorphic to the boundary of a $(d + 1)$ -simplex.

(All PL^+ d -spheres and d -balls are PL. The converse is true for all $d \neq 4$ and unknown for $d = 4$ [54]: A priori some 4-spheres or 4-balls might not be PL^+ , whereas all 4-manifolds are PL.)

Theorem 3.14 (Forman [25, Theorem 5.2]). *Let M be any PL^+ d -ball or d -sphere. By performing a finite sequence of bisections, M can be subdivided to a shellable and endo-collapsible triangulation.*

Proof. For any PL^+ d -ball (resp. d -sphere) M , there exists a triangulation M' which can be obtained from M via a finite sequence of bisections and can also be obtained from the d -simplex (resp. the boundary of the $(d + 1)$ -simplex) via another finite sequence of bisections. Since bisections preserve shellability and simplices (resp. boundaries of simplices) are shellable this M' is shellable as well. Shellable manifolds are endo-collapsible; cf. Theorem 4.1 below or Chari [15]. \square

So, subdividing eventually induces endo-collapsibility. However, there is no integer k such that every 3-sphere has endo-collapsible k -th barycentric subdivision. For each k , in fact, one can produce a 3-sphere whose k -th barycentric subdivision is not endo-collapsible and not even LC. For details, see Section 4.2. The reason for this is that any discrete Morse function on a manifold M gives upper bounds for the homology not only of M , but also of the complement of any subcomplex of M .

Theorem 3.15. *Let $d \geq 2$ be an integer. Let M be a PL d -manifold. Let L be a subcomplex of M , with $\dim L \leq d - 2$. Let L^{int} be the subcomplex of M determined by the facets of L not in ∂M . Let $f_k(L^{\text{int}})$ be the number of k -faces of L^{int} . If g is any boundary-critical discrete Morse function on M , let $c_k^{\text{int } M \cap L}(g)$ be the number of critical k -cells of L^{int} .*

The space $|M| - |L^{\text{int}}|$ is homotopy equivalent to a cell complex with 1 point and at most

$$c_{d-k}^{\text{int}}(g) - c_{d-k}^{\text{int } M \cap L}(g) + f_{d-k-1}(L^{\text{int}})$$

cells of dimension k , for each $k = 1, \dots, d$.

Proof. The argument is very similar to the proof of Theorem 3.3 and of [8, Theorem 2.19]. For completeness, we sketch it anyway:

- (i) We write the sequence of collapses and removals of critical cells given by g .
- (ii) We ignore the faces in L^{int} , while we progressively attach to one another the dual blocks of all the other faces of the sequence, maintaining their order.

(iii) Eventually, we obtain a cell complex which is homotopy equivalent, not to the whole M , but just to $|M| - |L^{\text{int}}|$.

For example, the list described in item (i) will start with some critical d -cell Δ , followed by a $(d - 1)$ -cell σ and another d -cell Σ . Since L is lower-dimensional, none of Δ, σ, Σ lies in L . So we start with the point Δ^* ; we add the 0-cell Σ^* and attach the 1-cell σ^* , with endpoints Δ^* and Σ^* ; and so on.

Just as in the proof of Theorem 3.3, the progressive attachments of the dual blocks often preserve the homotopy type. There are in fact only two exceptional cases in which the homotopy type changes by the addition of a cell:

- (A) The removal of a critical i -face σ that is not in L^{int} dually corresponds to the attachment of a $(d - i)$ -cell σ^* along its whole boundary.
- (B) An elementary collapse (σ, Σ) that removes one $(i - 1)$ -face δ in L^{int} and one i -face Δ not in L^{int} dually corresponds to the attachment of the sole $(d - i)$ -cell Δ^* along its whole boundary.

(The case when we collapse two faces δ, Δ , both in L^{int} , does not change the homotopy type: dually, nothing happens. Also, if σ is a critical cell that belongs to L^{int} , we do not attach its dual, so the homotopy type is trivially preserved.)

Case (A) occurs exactly $c_i^{\text{int}}(g) - c_i^{\text{int} M \cap L}(g)$ times, which is the number of critical interior i -cells of g that are not in L^{int} . Case (B) occurs at most $f_{i-1}(L^{\text{int}})$ times, which is the number of $(i - 1)$ -faces δ in L^{int} . (Each of these δ is removed together with some i -face, which might or might not be in L^{int} .) Setting $k = d - i$ we conclude. \square

Example 3.16. Let m be an integer greater than 2. Let L be a knot realized as a 3-edge subcomplex of a 3-sphere S (cf. Section 4.2). Since S has no boundary, $L^{\text{int}} = L$. Let g be any discrete Morse function on S . By Theorem 3.15, the space $|S| - |L|$ is homotopy equivalent to a complex with one point and at most $c_2(g) + 3$ cells of dimension one. Thus the fundamental group of $|S| - |L|$ has a presentation with at most $c_2(g) + 3$ generators. Now, the fundamental group of $|S| - |L|$ is the so-called *knot group* of L , a well-known invariant which depends only on the knot type and not on the triangulation chosen. Suppose the knot L is so tangled that any presentation of its group requires at least t generators. Then obviously $c_2(g) + 3 \geq t$. This yields the numerical condition $c_2(g) \geq t - 3$ on every discrete Morse function g on S . Compare with Theorem 4.18.

Example 3.17. Let L be a knot realized as an m -edge subcomplex of a 3-ball B so that only one edge $[x, y]$ of L belongs to the interior of B . (See Section 4.2.) By Theorem 3.15, the fundamental group of $|B| - |[x, y]|$ admits a presentation with at most $c_2^{\text{int}}(g) + 1$ generators, where g is any boundary-critical discrete Morse function on B . Suppose any presentation of the fundamental group of $|B| - |[x, y]|$ requires at least t generators: Then for every discrete Morse function g on B we have $c_2^{\text{int}}(g) + 1 \geq t$, whence $c_2^{\text{int}}(g) \geq t - 1$. Notice the gap with Example 3.16.

The crucial idea for the proof of Theorem 3.15 comes from a 1991 paper by Lickorish [46], who treated the special case when M is a 3-sphere, $L^{\text{int}} = L$ is a 1-sphere, $c_1(g) = c_2(g) = 0$ and $f_0(L) = f_1(L) = 3$. A generalization by the author and Ziegler to the case $\partial M = \emptyset$, $L^{\text{int}} = L$ and $c_{d-1}(g) = 0$ can be found in [8]; see also [4, Thm. 5.5.4].

Theorem 3.15 represents a step towards a relative version of discrete Morse theory. It might seem bizarre to focus on pairs (M, L) , with M a PL manifold and

L a subcomplex of M (not necessarily a submanifold). However, the PL assumption is necessary to activate duality, which yields the crucial tool to find models for the complement of the subcomplex. Intuitively, the fewer critical cells a Morse function on M has, the simpler our model for $|M| - |L|$ will be. On the other hand, if we expect a priori a complicated model for $|M| - |L|$ (as in Example 3.16), then any discrete Morse function on our manifold must have plenty of critical cells.

3.4. Patching boundary-critical discrete Morse functions together. The following theorem can be seen as an extension of a result of the author and Ziegler [8, Lemma 2.23], who studied the case $k = d - 1$ and $c_{d-1}(f) = c_{d-1}(g) = 0$.

Theorem 3.18. *Let $M = M_1 \cup M_2$ be three d -pseudo-manifolds such that $M_1 \cap M_2$ is a $(d - 1)$ -pseudo-manifold. Let f and g be equatorial boundary-critical discrete Morse functions on M_1 and M_2 , respectively. Let h be a boundary-critical discrete Morse function on $M_1 \cap M_2$, with $c_{d-1}^{\text{int}}(h) = 1$. There exists a boundary-critical discrete Morse function u on M with*

$$c_k^{\text{int}}(u) = \begin{cases} c_k^{\text{int}}(f) + c_k^{\text{int}}(g) + c_k^{\text{int}}(h), & \text{if } k \text{ is in } \{0, \dots, d - 2\}, \\ c_k^{\text{int}}(f) + c_k^{\text{int}}(g) + c_k^{\text{int}}(h) - 1, & \text{if } k \text{ is in } \{d - 1, d\}. \end{cases}$$

Proof. Choose a $(d - 1)$ -face σ in $M_1 \cap M_2$. Let Σ_i be the unique face of M_i containing σ ($i = 1, 2$). Without loss of generality, we can assume that Σ_1 is the unique critical d -cell of f , Σ_2 is the unique critical d -cell of g and σ is the unique critical $(d - 1)$ -cell of h . The idea is to first “drill” inside $M_1 - \Sigma_1$ using the discrete Morse function f , then to collapse away the pair (σ, Σ_2) , then to drill inside $M_2 - \Sigma_2$ using g , and finally to drill inside $M_1 \cap M_2$ using h . Formally, we choose a positive integer p and we define a real-valued map u_p on M as follows:

$$u_p(\tau) = \begin{cases} g(\Sigma_2) & \text{if } \tau = \sigma, \\ f(\tau) + p & \text{if } \tau = \Sigma_1, \\ f(\tau) & \text{if } \tau \text{ is in the interior of } M_1 \text{ and } \tau \neq \Sigma_1, \\ g(\tau) & \text{if } \tau \text{ is in the interior of } M_2, \\ h(\tau) - p & \text{if } \tau \text{ is in the interior of } M_1 \cap M_2 \text{ and } \tau \neq \sigma, \\ \dim \tau - p^2 & \text{if } \tau \text{ is in } \partial M. \end{cases}$$

The previous six cases form a partition of M ; the sixth may be void.

For p large, the map u_p achieves its maximum on Σ_1 and its minimum on all vertices of ∂M ; moreover, for p large the whole boundary of M is critical. Since $u_p(\sigma) = g(\Sigma_2) = u_p(\Sigma_2)$, the cells σ and Σ_2 form a collapse pair. With the exception of Σ_1 and Σ_2 , u_p coincides with g on the interior of M_2 and with f on the interior of M_1 . On the interior cells of $M_1 \cap M_2$ except σ , the map u_p is just h shifted by the constant $-p$. This way, if p is large, for each $(d - 1)$ -cell δ of $M_1 \cap M_2$ one has $h(\delta) - p < \min \{f(\Delta_1), g(\Delta_2)\}$, where Δ_i is the d -cell of M_i containing δ . Also, for p large, u_p attains a larger value on σ than on any of the $(d - 2)$ -faces in the boundary of σ . In conclusion, for p sufficiently large the map u_p is a boundary-critical discrete Morse function.

By construction, the interior critical cells of u_p are either interior critical cells of f or interior critical cells of g or interior critical cells of h . The only exceptions are the cells Σ_2 (of dimension d) and σ (of dimension $d - 1$), which are critical under g and h , respectively, but not critical under u . □

Next, we deal with cones over manifolds. Let P be a d -dimensional polytope and let v be a point not belonging to the affine hull of P . The cone $v * P$ is the

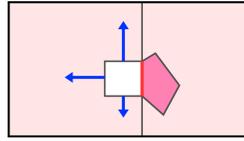

FIGURE 7. How to “patch” together boundary-critical discrete Morse functions. First drill on the left, then perforate the barrier, then drill on the right, and finally take away what is left of the barrier.

convex hull of all vertices of P , plus v . This $v * P$ is a $(d + 1)$ -polytope in which P appears as a facet; cf. [78, Chapter 1]. By convention, we also set $v * \emptyset = v$. Given a d -dimensional polytopal complex C , the $(d + 1)$ -complex $v * C$ is then defined by

$$v * C := C \cup \{v * \sigma : \sigma \text{ is a face of } C\}.$$

For the next result, we recall that we assume polarity (resp. equatoriality) for all functions on manifolds without boundary (resp. with boundary).

Theorem 3.19. *Let M be a d -manifold. Let f be any boundary-critical discrete Morse function on M . There is a boundary-critical discrete Morse function “ $v * f$ ” on $v * M$ such that $c_0^{\text{int}}(v * f) = c_1^{\text{int}}(v * f) = 0$ and*

$$c_k^{\text{int}}(f) = c_{k+1}^{\text{int}}(v * f) \quad \text{for each } k \text{ in } \{1, \dots, d\}.$$

*Conversely, if g is a boundary-critical discrete Morse function on the pseudo-manifold $v * M$, there is a boundary-critical discrete Morse function f on M , with $c_0^{\text{int}}(f) = 1$ or 0 according to whether ∂M is empty or not, and*

$$c_k^{\text{int}}(f) = c_{k+1}^{\text{int}}(g) \quad \text{for each } k \text{ in } \{1, \dots, d\}.$$

Proof. Observe first that all internal faces of $v * M$ are of the form $v * \sigma$ for some σ in M . Let f be a boundary-critical discrete Morse function on M . If M is a manifold with boundary and p is a positive integer, define a map $u_p : M \rightarrow \mathbb{R}$ by setting

$$u_p(\tau) = \begin{cases} f(\sigma) & \text{if } \tau = v * \sigma \text{ for some non-empty face } \sigma \text{ of } M, \\ -p + \dim \tau & \text{if } \tau \text{ is a face of } M \text{ or if } \tau = v. \end{cases}$$

If M is a manifold without boundary and x is the unique critical 0-cell of f , instead set

$$u_p(\tau) = \begin{cases} f(\sigma) & \text{if } \tau = v * \sigma \text{ for some non-empty face } \sigma \text{ of } M, \sigma \neq x, \\ -p + \dim \tau & \text{if } \tau \text{ is a face of } M, \\ -p + 1 & \text{if } \tau = v \text{ or if } \tau = v * x. \end{cases}$$

For p sufficiently large, u_p yields the desired boundary-critical Morse function on $v * M$. Notice that when $\partial M = \emptyset$ the vertex v forms a collapse pair with $v * x$. For each $i > 0$, there is an obvious bijection between the critical i -cells of M with respect to f and the critical interior $(i + 1)$ -cells of $v * M$ with respect to u_p . In case M is a manifold with boundary, M has no critical interior 0-cell. In case M is a manifold without boundary, there is a critical interior 0-cell v ; however, the corresponding 1-cell $v * x$ of $v * M$ is paired with v .

Conversely, given a boundary-critical discrete Morse function g on $v * M$, setting $f(\sigma) := g(v * \sigma)$ for each σ in M one obtains a boundary-critical discrete Morse function on M . \square

The barycentric subdivision of a collapsible (respectively, endo-collapsible) manifold is collapsible (resp. endo-collapsible). More generally, a discrete (resp. a boundary-critical discrete) Morse function on M induces discrete (resp. boundary-critical discrete) Morse functions on $\text{sd } M$ with the same number of critical cells [25]. Sometimes a triangulation “improves” by taking subdivisions, so $\text{sd } M$ might admit Morse functions with fewer critical cells; see [6].

The last result of this section shows how to get from a *boundary-critical discrete* Morse function on a manifold M with boundary to a *discrete* Morse function on $\text{sd } M$. Then we show how to obtain a *boundary-critical discrete* Morse function on $\text{sd } M$ starting with a *discrete* Morse function on M . We will need this type of result in Sections 4.1 and 4.2.

Theorem 3.20. *Let M be a PL d -manifold with boundary. Let F_1, \dots, F_B be a list of all the non-empty boundary faces of M . Let F_{B+1}, \dots, F_M be a list of all the non-empty interior faces of M . For each i in $\{1, \dots, B\}$, let h_i be a discrete Morse function on the ball $\text{link}_{\text{sd } M} F_i$. For each j in $\{1, \dots, M\}$, let g_j be a boundary-critical discrete Morse function on the manifold $\text{link}_{\text{sd } M} F_j$.*

(1) *If f is a boundary-critical discrete Morse function on M , there exists a discrete Morse function F on $\text{sd } M$ such that*

$$c_k(F) = \begin{cases} c_{d-k}^{\text{int}}(f) + \sum_{i=1}^B c_{k-1}(h_i) + \sum_{j=B+1}^M c_{k-1}^{\text{int}}(g_j) & \text{if } k \geq 2, \\ c_{d-k}^{\text{int}}(f) & \text{if } k \leq 1. \end{cases}$$

(2) *If f is a discrete Morse function on M , there exists a boundary-critical discrete Morse function F on $\text{sd } M$ such that*

$$c_k^{\text{int}}(F) = \begin{cases} c_{d-k}(f) + \sum_{j=1}^M c_{k-1}^{\text{int}}(g_j) & \text{if } k \geq 2, \\ c_{d-k}(f) & \text{if } k \leq 1. \end{cases}$$

Corollary 3.21. *Let B be a PL d -ball. Suppose that $\text{sd } \text{link}_B \sigma$ is endo-collapsible for each non-empty interior face σ of B .*

(1) *If B is endo-collapsible and in addition $\text{link}_{\text{sd } B} \delta$ is collapsible for each non-empty face δ of ∂B , then $\text{sd } B$ is collapsible.*

(2) *If B is collapsible and in addition $\text{link}_{\text{sd } B} \delta$ is endo-collapsible for each non-empty face δ of ∂B , then $\text{sd } B$ is endo-collapsible.*

Here we prove only Corollary 3.21, which is what we really need for the applications. The proof for Theorem 3.20 is a straightforward generalization, using Theorem 3.19 and Theorem 3.18.

Proof. Set $C := B^* - (\partial B)^*$.

(1) The dual complex B^* cellularly collapses onto C , which in turn cellularly collapses onto a point, by Corollary 3.11. All we need to show is that (i) $\text{sd } C$ is collapsible and (ii) $\text{sd } B$ collapses onto $\text{sd } C$.

To prove (i), suppose a cellular collapse of C removes two cells Σ^* and σ^* , where σ is a codimension-one face of Σ in the interior of B . Inside $\text{sd}(B)$, $|\sigma^*|$ is triangulated as a cone with the barycenter $\hat{\sigma}$ of σ as its apex and $\text{link}_{\text{sd } B} \sigma$ as its basis. By the assumption, $\text{link}_{\text{sd } B} \sigma$ and $\text{link}_{\text{sd } B} \Sigma$ are endo-collapsible spheres. By Theorem 3.19, $D := \hat{\sigma} * \text{link}_{\text{sd } B} \sigma$ and $E := \hat{\Sigma} * (\text{link}_{\text{sd } B} \Sigma)$ are endo-collapsible balls. So, ∂D is an endo-collapsible sphere containing the endo-collapsible ball E . In particular, for any facet τ of E , $\partial D - \tau$ is collapsible. By coning with apex $\hat{\sigma}$, we obtain a collapse of $D - \hat{\sigma} * \tau - \tau$ onto $\partial D - \tau$. By the

endo-collapsibility of E , the ball $\partial D - \tau$ collapses onto $\partial D - E$. Therefore, for any facet τ of E we have a (simplicial) collapse of $D - \hat{\sigma} * \tau - \tau$ onto $\partial D - E$. This means we can represent the cellular collapse (Σ^*, σ^*) as a sequence of (several) elementary collapses in the barycentric subdivision of B . Thus the cellular collapse of C onto a point v translates into a (simplicial) collapse of $\text{sd } C$ onto $\text{sd } v = v$.

To prove (ii), we choose a 0-cell v in ∂B : Inside $\text{sd } B$, the topological ball $|v^*|$ is triangulated as a cone with apex $\hat{v} = v$ and basis $\text{link}_{\text{sd } B} v$. The basis is collapsible by assumption. If we write the list of faces removed in the collapse and replace every face τ with $v * \tau$, we obtain a collapse of the cone onto its basis. (See also Theorem 4.9, part (i).) Thus we may remove $|v^\diamond|$ and $|v^*|$ via elementary collapses. We do this for each boundary vertex v . Next, we choose an edge e of ∂B . The open dual block $|e^*|$ inside $\text{sd } B$ is triangulated as a join of \hat{e} with a collapsible complex K , namely, the subdivision of the link of e . Reasoning as before, $\hat{e} * K$ can be collapsed onto K , which topologically corresponds to the removal of $|e^\diamond|$ and $|e^*|$. After doing this for all boundary edges, we pass to boundary 2-faces, and so on. Eventually, we realize the cellular collapse of B^* onto C as a collapse of $\text{sd } B$ onto $\text{sd } C$.

- (2) By Corollary 3.11, the complex $B^* - v^*$ cellularly collapses onto the dual of ∂B . Let V be the subcomplex of $\text{sd } B$ with the same underlying space of $B^* - v^*$. Our goal is to show that (i) V collapses onto $\text{sd } \partial B$ and (ii) $\text{sd } B$ minus a facet collapses onto V . The proof of (i) is analogous to the proof of item (1), part (i). To prove part (ii), all we need to show is that the triangulation of $|v^*|$ inside $\text{sd } B$ is endo-collapsible. This triangulation is precisely a cone with apex v and basis $\text{link}_{\text{sd } B} v$. The basis is endo-collapsible by assumption, so via Theorem 3.19 we are done. \square

4. APPLICATIONS TO CLASSICAL COMBINATORIAL TOPOLOGY

4.1. Constructible and shellable manifolds. In this section we study constructible complexes. We prove that all constructible pseudo-manifolds are endo-collapsible (Theorem 4.1). Then we show that the barycentric subdivision of a constructible simplicial d -ball is collapsible (Theorem 4.13).

Constructibility is a strengthening of the Cohen-Macaulay notion introduced by Hochster in the seventies [38]. Recursively, a *pure* d -complex C is constructible if and only if either C has only one facet, or $C = C_1 \cup C_2$, where

- (i) C_1 and C_2 are constructible d -complexes and
- (ii) $C_1 \cap C_2$ is a constructible $(d - 1)$ -complex.

The definition of constructibility may be strengthened by specifying that C_2 should be a simplex. The notion arising this way is called *shellability* and has been extensively studied. Shellable complexes can be assembled one simplex at a time so that each new simplex is attached to the previous ones alongside some (or maybe all) of its boundary facets. All shellable complexes are constructible, but some constructible 2-complexes [33] and some constructible 3-balls [48] are not shellable. Also, it is easy to show that all shellable balls are collapsible [18], but the question of whether all constructible d -balls are collapsible is open for each $d \geq 4$ [8].

Newman showed that all 2-balls are shellable [57]; in particular, they are all constructible and collapsible. However, some 3-balls are not collapsible [9]. Every constructible 3-ball B with more than one facet is *splittable*, that is, it contains an

embedded 2-disk D such that $\partial D \subset \partial B$. Lickorish [45] showed that some 3-balls do not split. By taking cones over Lickorish's example, one obtains non-constructible d -balls for each $d \geq 3$. The reason for the existence of non-constructible spheres and non-collapsible balls goes back to classical knot theory; see Section 4.2. By *knotted* manifolds we mean 3-manifolds containing a non-trivial 3-edge knot in their 1-skeleton. Using a simple induction on the number of facets, Hachimori and Ziegler [35] showed that no constructible 3-manifold is knotted. On the other hand, we will see in Lemma 4.16 that a 3-sphere may contain an arbitrarily complicated 3-edge knot in its 1-skeleton. Removing a 3-cell from one such sphere, we obtain a knotted 3-ball with the same complicated 3-edge knot. All the examples produced this way are Cohen-Macaulay complexes that are not constructible.

Summing up, for d -manifolds (with or without boundary)

(3) shellable \implies constructible \implies Cohen-Macaulay \implies strongly connected,

and all implications are strict for $d \geq 3$.

The next theorem strengthens a result by the author and Ziegler [8, Lemma 2.23], who showed that constructible pseudo-manifolds are LC, and a result of Chari [15, Prop. 3], who showed that all shellable pseudo-manifolds without boundary are endo-collapsible.

Theorem 4.1. *All constructible pseudo-manifolds are endo-collapsible.*

Proof. If M has only one facet Δ , then $M - \Delta$ is the boundary of M and there is nothing to prove. Otherwise, write $M = C_1 \cup C_2$ so that C_1, C_2 are constructible d -complexes with a constructible $(d-1)$ -dimensional intersection. Since every $(d-1)$ -face of M is contained in at most two facets of M , every $(d-1)$ -face of C_1 is contained in at most two facets of C_1 ; the same holds for C_2 , of course. Also, every facet of $C_1 \cap C_2$ is contained in exactly one facet of C_1 and in exactly one facet of C_2 . Therefore, the C_i are constructible pseudo-manifolds with non-empty boundary (because $C_1 \cap C_2$ is contained in the boundary of each C_i). By a result of Zeeman [76], both the C_i are d -balls. $C_1 \cap C_2$ is either a ball or a sphere, depending on whether M is a ball or a sphere. By induction, we can assume that C_1, C_2 and $C_1 \cap C_2$ are endo-collapsible. Using Theorem 3.18 (see also Figure 7), we conclude that C is also endo-collapsible. \square

Remark 4.2. The converse of Theorem 4.1 is false: Some spheres and balls are endo-collapsible but not constructible. In the next section, we will show that endo-collapsible manifolds may be knotted unless the knot is “too complicated” (cf. Theorem 4.19). In contrast, all knotted manifolds are not constructible.

Corollary 4.3. *If B is a constructible d -ball, then B collapses onto its boundary minus a facet.*

Remark 4.4. Corollary 4.3 shows that any shellable ball admits *two* natural collapsing sequences, one collapsing the ball onto a single vertex and the other one collapsing the ball onto its boundary minus a facet. In general, these two sequences are “not compatible”: In fact, when $d \geq 4$ any PL $(d-1)$ -sphere (including the ones generated in Theorem 4.18) is combinatorially equivalent to the boundary of some shellable d -ball [59, Theorem 2, p. 79]. So if B is a shellable d -ball, $d \geq 4$, and σ is a $(d-1)$ -cell in ∂B , we have that (1) B always collapses onto $\partial B - \sigma$, (2) B always collapses onto a point, but (3) “often” $\partial B - \sigma$ does not collapse onto

a point. (The adverb “often” can be made precise by asymptotically counting the combinatorial types with respect to the number of facets; see Section 3.2.)

Corollary 4.5. *If S is a shellable sphere, then $S - \Delta$ is collapsible for all facets Δ .*

Remark 4.6. If S is a shellable sphere and Δ is the last facet of some shelling, then $S - \Delta$ is *shellable*. Hachimori and Ziegler [35] asked whether the shellability of S implies the shellability of $S - \Delta$ for *all* facets Δ . In other words, is any facet of a shellable sphere the last facet of some shelling? This problem is still open. (The answer is “yes” for boundaries of polytopes; see [78, p. 243].) Corollary 4.5 could be viewed as a step towards a positive answer, since all shellable balls are collapsible.

Example 4.7. Rudin’s ball [65] is a non-shellable geometric subdivision of a tetrahedron. Chillingworth [16] showed that any geometric subdivision of a convex 3-polytope collapses onto its boundary minus a facet. In particular, Rudin’s ball is endo-collapsible. In fact, it is also constructible [63].

If a d -sphere S splits into two endo-collapsible balls that intersect in an endo-collapsible $(d - 1)$ -sphere, by Theorem 3.18 S is endo-collapsible. The next lemma shows that the requirement on the intersection is no longer needed if we know that one of the two 3-balls is collapsible:

Lemma 4.8. *Let S be a d -sphere that splits into two d -balls B_1 and B_2 so that $B_1 \cap B_2 = \partial B_1 = \partial B_2$. If B_1 is endo-collapsible and B_2 is collapsible, then S is endo-collapsible.*

Proof. Let Σ be a facet of B_1 . The collapse of $B_1 - \Sigma$ onto ∂B_1 can be read as a collapse of $S - \Sigma$ onto B_2 . However, B_2 is collapsible, so $S - \Sigma$ is collapsible. \square

Theorem 4.9 (Cones and suspensions).

- (i) *If B is an arbitrary ball, $v * B$ is a collapsible ball. If B is collapsible, $v * B$ collapses onto B .*
- (ii) *A manifold M is endo-collapsible if and only if $v * M$ is endo-collapsible.*
- (iii) *If M is an endo-collapsible manifold, so is its suspension.*
- (iv) *If B is an endo-collapsible d -ball, $\partial(v * B)$ is an endo-collapsible d -sphere.*
- (v) *If B is a collapsible d -ball and ∂B is an endo-collapsible $(d - 1)$ -sphere, $\partial(v * B)$ is an endo-collapsible d -sphere.*
- (vi) *If B is an endo-collapsible d -ball and ∂B is an endo-collapsible $(d - 1)$ -sphere, B is collapsible.*
- (vii) *If B is an endo-collapsible $(d - 1)$ -ball contained in an endo-collapsible $(d - 1)$ -sphere A , the d -ball $v * A$, where v is a new vertex, collapses onto $A - B$.*

Proof. Item (i) is well known; see e.g. Welker [72]. Item (ii) follows directly from Theorem 3.19.

Item (iii) follows from item (ii) and Theorem 3.18 (or alternatively, from item (ii), Lemma 4.8 and the fact that all cones are collapsible).

Item (iv) follows from Lemma 4.8: The sphere $\partial(v * B)$ splits at the union of the ball $v * \partial B$ (which is collapsible) and the ball B (which is endo-collapsible) with $(v * \partial B) \cap B = \partial B = \partial(v * \partial B)$. Item (v) is very similar: It follows from Lemma 4.8, but this time we use that $v * \partial B$ is endo-collapsible and B is collapsible.

As for item (vi), let σ be a $(d - 1)$ -face of ∂B and Σ the unique d -cell containing σ . The collapse of $B - \Sigma$ onto ∂B can be rewritten as a collapse of B onto $\partial B - \sigma$. If the latter complex is collapsible onto a point, so is B . This settles (vi).

We are left with (vii). Let σ be a facet of B . Since A is endo-collapsible, by item (ii) $v * A$ is endo-collapsible, so $v * A - v * \sigma$ collapses onto $\partial(v * A) = A$. Equivalently, $v * A - v * \sigma - \sigma$ collapses onto $A - \sigma$. Since the removal of $(\sigma, v * \sigma)$ from $v * A$ is an elementary collapse, we conclude that $v * A$ collapses onto $A - \sigma$. But by the endo-collapsibility of B , $B - \sigma$ collapses onto ∂B . In particular, $A - \sigma$ collapses onto $A - B$. \square

Corollary 4.10. *Let v be a vertex of a d -sphere S .*

- (i) *If the deletion $\text{del}_S v$ is an endo-collapsible d -ball, then S is an endo-collapsible d -sphere.*
- (ii) *If the deletion $\text{del}_S v$ is a collapsible d -ball and in addition $\text{link}_S v$ is endo-collapsible, then S is an endo-collapsible d -sphere.*

Proof. Set $B := \text{del}_S v$. Since $\partial B = \text{link}_S v$, we have $\partial(v * B) = B \cup (v * \partial B) = B \cup (v * \text{link}_S v) = S$. The first item then follows from Theorem 4.9, item (iv) and the second from Theorem 4.9, item (v). \square

The converse of implication (i) above does not hold: A counterexample is given by Lutz's sphere $S_{13,56}^3$ (see the proof of Corollary 4.21). This sphere is endo-collapsible, but deleting one of the three vertices of the knot, one obtains a 3-ball that cannot be endo-collapsible by Corollary 4.21.

Example 4.11. Let S be the boundary of a $(d + 1)$ -polytope P . Then:

- (1) S is a shellable d -sphere [78, p. 240];
- (2) S^* is also a shellable d -sphere (it is the boundary of the dual polytope of P);
- (3) $\text{link}_S v$ is a shellable $(d - 1)$ -sphere, for each vertex v of S [78, Ex. 8.6, p. 282];
- (4) $S - \Delta$ is a shellable d -ball, for each facet Δ of S [78, Corollary 8.13];
- (5) $\text{del}_S v$ is a shellable d -ball, for each vertex v of S [78, Corollary 8.13].

By Theorem 4.1, S , S^* , $\text{link}_S v$, $\text{del}_S v$, and $S - \Delta$ are all endo-collapsible. The last two complexes are also collapsible.

As we mentioned above, all shellable balls are collapsible. Since constructibility is a slight weakening of the shellability property, it is natural to ask whether all *constructible* balls are collapsible. (This was also asked by Hachimori [32] and in our work with Ziegler [8].) The problem is open for all dimensions greater than three. Here we present a partial positive answer for all dimensions.

Lemma 4.12. *The link of any non-empty face in a constructible simplicial ball is constructible.*

Proof. Let C be a constructible d -ball. We proceed by double induction on the dimension and the number of facets. If C has only one facet, then C is a simplex, and the claim is obvious. If C has more than one facet, then $C = C_1 \cup C_2$. By the inductive assumption, the three complexes $\text{link}_{C_1} \sigma$, $\text{link}_{C_2} \sigma$ and $\text{link}_{C_1 \cap C_2} \sigma$ are constructible. Then $\text{link}_C \sigma = \text{link}_{C_1} \sigma \cup \text{link}_{C_2} \sigma$, with $\text{link}_{C_1} \sigma \cap \text{link}_{C_2} \sigma = \text{link}_{C_1 \cap C_2} \sigma$. \square

Theorem 4.13. *The barycentric subdivision of a simplicial constructible ball is collapsible.*

Proof. We proceed by induction on the dimension: The case $d = 2$ is trivial, since all 2-balls are collapsible. The case $d = 3$ was proven in [8]. Let B be a constructible d -ball, $d \geq 4$. By Theorem 4.1, B is PL endo-collapsible. If δ is any boundary face

of B , then $\text{link}_B \delta$ is a constructible ball by Lemma 4.12 and has lower dimension than B . By the inductive assumption, $\text{sd link}_B \delta$ is collapsible. Moreover, for each non-empty face σ of B , $\text{sd link}_B \sigma$ is constructible by Lemma 4.12 and thus endo-collapsible by Theorem 4.1. Also, all constructible spheres and balls are PL; in particular, $\text{sd link}_B \sigma$ is PL. Since B is simplicial, $\text{sd link}_B \sigma = \text{link}_{\text{sd } B} \sigma$ for all σ . Via Corollary 3.21, part (1), we conclude that $\text{sd } B$ is collapsible. \square

Remark 4.14. For the previous result we did not require ∂B to be triangulated “nicely”: A priori, if δ is a boundary facet of B , the complex $\text{link}_{\partial B} \delta$ might not be endo-collapsible. In fact, in the next section we will show how to produce a simplicial 3-sphere S with a 3-edge knot corresponding to the connected sum of 6 trefoils in its 1-skeleton. Via Theorem 4.18 we will see that neither the barycentric subdivision $\text{sd } S$ nor the first suspension $S' = (v * S) \cup (w * S)$ can be LC. Now, if B is a shellable 5-ball with $\partial B = S'$ (cf. Pachner [59, Theorem 2, p. 79]), this B is constructible and $\text{sd } B$ is collapsible. However, $\text{sd link}_{\partial B} v = \text{sd link}_{S'} v = \text{sd } S$ is not LC.

Remark 4.15. Is every link in a shellable complex shellable? We know the answer is positive for simplicial or cubical complexes [17], but in general this still seems to be an open problem.

4.2. Knots inside 3-manifolds. A *spanning edge* in a 3-ball B is an interior edge that has both endpoints on ∂B . A *K -knotted spanning edge* of a 3-ball B is a spanning edge $[x, y]$ such that some simple path on ∂B between x and y completes the edge to a non-trivial knot K . (*Non-trivial* means that it does not bound a disk. All the knots we consider are *tame*, that is, realizable as 1-dimensional subcomplexes of some triangulated 3-sphere.) The knot type does not depend on the boundary path chosen, so the knot is determined by the edge. By *knot group* we mean the fundamental group of the knot complement inside the 3-sphere. For further definitions, e.g., of *connected sums* of knots, of *2-bridge* knots, of *spanning arcs* and so on, we refer either to Kawauchi [42] or to our paper with Ziegler [8]. “LC 3-balls” and “endo-collapsible 3-balls” are the same. (The proof is elementary; see e.g. Corollary 4.32.)

In this section, we prove that endo-collapsible 3-balls cannot contain any knotted spanning edge (Corollary 4.21). This improves a result of the author and Ziegler, who showed in [8, Proposition 3.19] that endo-collapsible 3-balls *without interior vertices* cannot contain any knotted spanning edges. Our proof is not an extension of the proof of [8, Section 3.2], but rather an application of Theorem 3.15.

Corollary 4.21 establishes a concrete difference between collapsibility and endo-collapsibility. In fact, some collapsible 3-balls have knotted spanning edges [8, 36, 47]. We also show that the barycentric subdivision of a collapsible 3-ball is endo-collapsible (Proposition 4.23). In particular, we re-cover a result by Bing: A ball with a knotted spanning edge cannot be collapsible if the knot is the double trefoil. In fact, its barycentric subdivision is not endo-collapsible by Theorem 4.19.

Lemma 4.16 (Furch [28], Bing [9]). *Any (tame) knot can be realized as a 3-edge subcomplex of some (simplicial) 3-sphere and as a knotted spanning edge of some (simplicial) 3-ball.*

Proof. Let K be an arbitrary knot. Take a sufficiently large pile of cubes, start from the top and drill a tubular hole downward along K . Stop one step before perforating the 3-ball. The result is a cubical 3-ball with a spanning edge $[x, y]$;

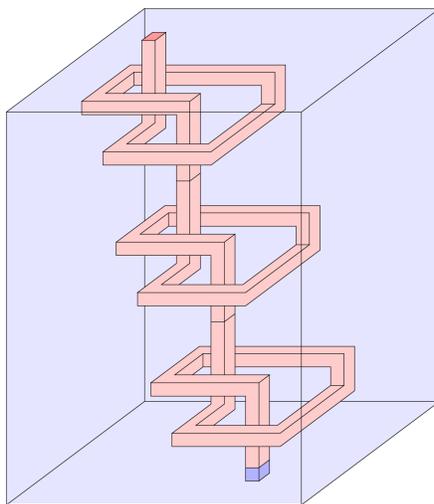

FIGURE 8. How to build a 3-ball B with a K -knotted spanning edge: (1) Take a pile of cubes and drill a tubular hole downward shaped as K , (2) stop one edge before reaching the bottom. (Here K is the connected sum of three trefoil knots.)

see Figure 8. (For a simplicial version, triangulate each cube into six tetrahedra without adding new vertices.) Any boundary path φ from x to y has to climb up the tube, thus completing the edge $[x, y]$ to a knotted loop, where the knot is isotopic to K . Thus we have realized K as a knotted spanning edge in a 3-ball B . Now pick a new vertex v : The 3-sphere $S_B = \partial(v * B)$ contains the subcomplex $[x, y] \cup [y, v] \cup [x, v]$, which is isotopic to $[x, y] \cup \varphi$ inside S_B . \square

Lemma 4.17 (Goodrick [29]). *If K is the connected sum of k trefoil knots embedded in a 3-sphere S , then the fundamental group of $|S| - |K|$ admits no presentation with fewer than $k + 1$ generators.*

Theorem 4.18 ([4, Cor. 5.5.5, p. 112]). *Let k and d be two arbitrary integers, with $d \geq 3$.*

- (1) *There exists a PL d -sphere M on which any discrete Morse function has more than k critical $(d - 1)$ -cells.*
- (2) *There exists a PL d -ball B on which any boundary-critical discrete Morse function has more than k critical interior $(d - 1)$ -cells.*

Proof. By Lemma 4.16, there is a 3-sphere S with a 3-edge knot K in its 1-skeleton, where the knot is the sum of $k + 3$ trefoils. By Lemma 4.17, every presentation of $\pi_1(|S| - |K|)$ has at least $(k + 3) + 1$ generators. Suppose that S admits a discrete Morse function with c_2 critical 2-cells. By Theorem 3.15, there is a connected cell complex with $c_2 + 3$ edges that is homotopy equivalent to $|S| - |K|$. In particular, the fundamental group of $|S| - |K|$ admits a presentation with $c_2 + 3$ generators, so $c_2 + 3 \geq k + 3 + 1$.

Higher-dimensional examples are obtained by suspensions. Suspending a 3-sphere S with a 3-edge knot K creates a 4-sphere S' with a 2-subcomplex K' with 6 triangles; topologically, $|S'| - |K'|$ is homotopy equivalent to $|S| - |K|$. Suppose S contains a 3-edge knot which is the sum of t trefoils. The $(d-3)$ -rd suspension of S is a d -sphere S' that contains a subcomplex K' with $3 \cdot 2^{d-3}$ facets. Assume this S' admits a discrete Morse function with c_{d-1} critical $(d-1)$ -cells. By Theorem 3.15, there is a connected cell complex with exactly $(c_{d-1} + 3 \cdot 2^{d-3})$ 1-cells that is homotopy equivalent to $|S'| - |K'|$, or equivalently to $|S| - |K|$. In particular, the fundamental group of $|S| - |K|$ admits a presentation with $c_{d-1} + 3 \cdot 2^{d-3}$ generators. Since $|S| - |K|$ is the knot group of the connected sum of t trefoil knots, $t < c_{d-1} + 3 \cdot 2^{d-3}$ by Lemma 4.17. In other words, if $t \geq c_{d-1} + 3 \cdot 2^{d-3}$ the PL d -sphere S' admits no discrete Morse function with c_{d-1} critical $(d-1)$ -cells. Setting $t := k + 3 \cdot 2^{d-3}$ we conclude.

As far as (2) is concerned, take a 3-ball B with a K -knotted spanning edge, where K is the sum of $k+1$ trefoil knots. The fundamental group of $|B| - |K^{\text{int}}|$ coincides with the knot group. By Lemma 4.17, any presentation of the fundamental group of $|B| - |K^{\text{int}}|$ has at least $(k+1)+1$ generators. Suppose B admits a boundary-critical discrete Morse function on B with c_2^{int} critical 2-cells. Note that K^{int} consists of one single edge. Theorem 3.15 yields a presentation of the fundamental group of $|B| - |K^{\text{int}}|$ with $c_2^{\text{int}} + 1$ generators. Therefore, $c_2^{\text{int}} + 1 \geq k + 1 + 1$. Higher-dimensional examples are obtained by taking cones over the previous example; cf. Theorem 3.19. Since taking cones does not increase the number of facets, there is no need to consider more complicated knots as the dimension increases. \square

Theorem 4.19. *Let K be any knot whose group admits no presentation with fewer than $k+1$ generators. (For example, the connected sum of k trefoil knots.) Then every 3-ball with a K -knotted spanning arc of e edges admits no boundary-critical discrete Morse function with $k-e$ critical interior 2-cells.*

Proof. Let B be a 3-ball with a K -knotted spanning edge. Choose a discrete Morse function on B , with c_2^{int} critical interior 2-cells, say. Let $[x, y]$ be the knotted spanning edge. Via Theorem 3.15 we obtain a presentation with $c_2^{\text{int}} + e$ generators of the fundamental group of $|B| - |[x, y]|$, yet the fundamental group of $|B| - |[x, y]|$ coincides with the knot group of K . By the assumption, $c_2^{\text{int}} + e \geq k + 1$. \square

Corollary 4.20. *Let r be a non-negative integer. Let K be the sum of 2^r trefoils. If a 3-ball B contains a K -knotted spanning edge, then $\text{sd}^r B$ is not endo-collapsible.*

Proof. Performing a single barycentric subdivision divides each edge into two. Thus the 3-ball $\text{sd}^r B$ has a K -knotted spanning arc consisting of 2^r edges. By Theorem 4.19, $\text{sd}^r B$ cannot admit a boundary-critical discrete Morse function without critical interior 2-cells. \square

Corollary 4.21. *Endo-collapsible 3-balls cannot contain knotted spanning edges. However, some endo-collapsible 3-balls and 3-spheres contain 3-edge knots in their 1-skeleton.*

Proof. The first part is the case $e = 1$, $k \geq 1$ of Theorem 4.19. For the second part, consider Lutz's sphere $S_{13,56}^3$ with 13 vertices and 56 tetrahedra [49]. This simplicial 3-sphere contains a trefoil knot on 3 edges. Let $B_{13,55}$ be the 3-ball obtained by removing from $S_{13,56}^3$ the tetrahedron $\Delta = \{1, 2, 6, 9\}$. With the help of a

computer program by Lutz, we showed that $B_{13,56}^3$ minus the facet $\Sigma = \{2, 6, 9, 11\}$ collapses onto the boundary of $B_{13,56}^3$, which is just the boundary of Δ . (See [4, Section 5.4.1].) So $B_{13,56}^3$ is both collapsible and endo-collapsible. In particular, the 3-sphere $S_{13,56}^3$ is endo-collapsible. It is neither shellable nor constructible, because of the presence of a 3-edge knot [35]. \square

Corollary 4.22. *For 3-balls, endo-collapsibility strictly implies collapsibility. The endo-collapsibility of a 3-ball B strictly implies the collapsibility of the dual cell complex B^* .*

Proof. All 2-spheres and all 2-balls are endo-collapsible. (This can be proven either directly or by using Theorem 4.1.) Let σ be a 2-cell in the boundary of an endo-collapsible 3-ball B , and let Σ be the unique 3-cell containing σ . A collapse of $B - \Sigma$ onto ∂B can be seen as a collapse of $B - \Sigma - \sigma$ onto $\partial B - \sigma$, and the other way around. Since σ is a free face of Σ , we conclude that B collapses onto $\partial B - \sigma$, which is a 2-ball and thus collapsible. So, all endo-collapsible 3-balls are collapsible. Now, choose a collapsible 3-ball B with a knotted spanning edge [8, 47]. (The knot can be the trefoil, or any 2-bridge knot.) In view of Corollary 4.21, B is collapsible but not endo-collapsible. Thus we can apply Corollary 3.11: B^* is an endo-collapsible 3-ball. In particular, B^* is collapsible. \square

We conclude by re-proving a classical result by Bing [9], who first described a non-collapsible ball by considering a 3-ball with a double-trefoil-knotted spanning edge:

Proposition 4.23. *The barycentric subdivision of a collapsible 3-ball is endo-collapsible.*

Proof. All 3-balls are PL. The link of any non-empty face in a 3-ball is either a 2-ball or a 2-sphere and thus endo-collapsible. Via Corollary 3.21, part (2), if B is collapsible, $\text{sd } B$ is endo-collapsible. \square

Remark 4.24. The previous result is best possible in the sense that the barycentric subdivision of a collapsible 3-ball need not be constructible. To see this, take any collapsible 3-ball with a knotted spanning edge (cf. Corollary 4.26 below), perform the barycentric subdivision and apply [35, Lemma 1].

Corollary 4.25 (Essentially Bing). *Let K be the connected sum of k trefoil knots or any knot whose group admits no presentation with fewer than $k + 1$ generators. Let B be a 3-ball with a K -knotted spanning arc of e edges. If $k \geq 2e$, then B cannot be collapsible.*

Proof. Consider the barycentric subdivision $\text{sd } B$ of B . This is a 3-ball with a K -knotted spanning arc of $2e$ edges. Since $k \geq 2e$, $\text{sd } B$ cannot be endo-collapsible by Theorem 4.19. Via Proposition 4.23 we conclude that B cannot be collapsible. \square

Corollary 4.26. *Let k be a positive integer and let K be the connected sum of k trefoil knots. A 3-ball with a K -knotted spanning arc of $2k$ edges can be endo-collapsible.*

Proof. In [8] we explained how to construct a collapsible 3-ball B_k with a K -knotted spanning arc of k edges. (See also [47, 36].) By Proposition 4.23, $\text{sd } B_k$ is endo-collapsible, yet $\text{sd } B_k$ has a K -knotted spanning arc of $2k$ edges. \square

4.3. Collapse depth versus ring-theoretic depth. In this section we relate what we have studied so far to classical notions in commutative algebra, e.g., Cohen–Macaulayness. We show that the collapse depth of a simplicial complex is never larger than the ring-theoretic depth of the associated Stanley–Reisner ring (Theorem 4.28). Sometimes the two depths coincide, but they can be arbitrarily far apart, as shown by Remark 4.29 and Proposition 4.33. We also give a hierarchy of properties of triangulated manifolds, valid for any dimension (Theorem 4.34).

The *algebraic depth* of a simplicial complex depends only on the homology of the underlying topological space. Intuitively, it measures how far we should go with the homology groups of a space and its links requiring them to be zero. The complexes of maximal algebraic depth are called *Cohen–Macaulay*: All triangulated d -balls and d -spheres are Cohen–Macaulay, but manifolds with different topologies may be Cohen–Macaulay as well. For example, Miller and Reiner found a PL Cohen–Macaulay non-simply-connected 4-manifold that embeds in \mathbb{R}^4 without being a 4-ball [51].

Here we present two similar notions (dual to one another) that seem equally interesting from the combinatorial point of view. The goal is to assign to each manifold an integer that (1) tells us about the vanishing of *homotopy* groups (and not just of *homology* groups), (2) takes into consideration how “nicely” M is triangulated. For example, the integer should increase if the $(d - 2)$ -skeleton of M contains complicated $(d - 2)$ -knots. We had already defined “collapse depth” in Section 2, but for convenience we repeat the definition here. We called the other notion “hamiltonian depth”. The name comes from the fact that a subcomplex H of a complex C is called k -hamiltonian if the k -skeleta of H and C coincide [21].

Definition 4.1 (Hochster, Reisner [52, p. 101]). Given a regular CW complex C and a field \mathbb{F} , we define

$$\text{adepth}_{\mathbb{F}} C = \max \left\{ m : \tilde{H}_i(\text{link}_C \sigma; \mathbb{F}) = 0 \text{ for all faces } \sigma \right. \\ \left. \text{and for all integers } i < m - \dim \sigma - 1 \right\},$$

where by convention $\text{link}_C \emptyset = C$. If $\text{adepth}_{\mathbb{F}} C$ is the same for all fields \mathbb{F} , we call such an integer the *algebraic depth* of C and denote it by $\text{depth } C$.

Definition 4.2 (Collapse depth). The *collapse depth* $\text{cdepth } M$ of a pseudo-manifold M is the maximal integer k for which there exists a boundary-critical discrete Morse function f on M with one critical d -cell and no internal critical $(d - i)$ -cells, for each $i \in \{1, \dots, k - 1\}$.

Definition 4.3 (Hamiltonian depth). The *hamiltonian depth* $\text{hdepth } C$ of a regular CW complex C is the maximal integer k for which there exists a k -subcomplex H of C that is $(k - 1)$ -hamiltonian and collapsible.

Lemma 4.27. *Let C be a (regular CW) complex. Let $k > 1$ an integer. Then:*

- (i) $\text{hdepth } C \geq 1$ if and only if C is connected;

- (ii) $\text{hdepth } C \geq k$ if and only if some discrete Morse function f on C has one critical 0-cell and no critical i -cells for each $i \in \{1, \dots, k-1\}$.
 In particular, if $\text{hdepth } C \geq k$, then C is at least $(k-1)$ -connected.

Proof. By definition, $\text{hdepth } C \geq 1$ means that there exists a collapsible 1-complex H that contains all vertices of C . Thus $\text{hdepth } C \geq 1$ if and only if C admits a spanning tree. This means that C is connected. Similarly, $\text{hdepth } C \geq k$ means that there exists a collapsible k -complex H that contains all $(k-1)$ -faces of C . Being collapsible, H is contractible. The complex C is obtained from H by attaching i -cells, with $i \geq k$. If $j \leq k-1$, these attachments leave the j -th homotopy group unchanged, so C is $(k-1)$ -connected. Finally, since H is a collapsible subcomplex of C , there is a discrete Morse function h on H with one critical 0-cell. We can extend g to a function f on M by setting $f \equiv g$ on H and $f(\sigma) = \dim \sigma + c$ if $\sigma \in M - H$. If c is chosen large enough, f is a discrete Morse function. This f might have plenty of critical cells; however, f has no critical cells of dimension smaller than k . \square

The locally constructible (LC) manifolds first studied by Durhuus and Jonsson [19] are precisely the manifolds with collapse depth at least two (cf. Theorem 3.5). The next theorem relates the two notions of collapse depth and hamiltonian depth to one another:

Theorem 4.28. *For any d -manifold M , $1 \leq \text{hdepth } M \leq \text{adepth } M \leq d$ and $1 \leq \text{cdepth } M \leq \text{adepth } M \leq d$. Moreover:*

- (i) *If $\text{hdepth } M \geq 2$ or $\text{cdepth } M \geq 2$, then M is simply connected.*
 (ii) *If $\text{hdepth } M = d$, then M is Cohen–Macaulay and at least $(\dim M - 1)$ -connected.*
If in addition $\partial M = \emptyset$, then M is a sphere.
 (iii) *If $\text{cdepth } M = d$, then M is either a sphere or a ball.*
In particular, M is Cohen–Macaulay and at least $(d - 1)$ -connected.
 (iv) *If M is PL, then $\text{cdepth } M \leq \text{hdepth } M^*$, $\text{hdepth } M \leq \text{cdepth } M^*$ and M is $(\text{cdepth } M - 1)$ -connected.*
If in addition $\partial M = \emptyset$, then $\text{cdepth } M = \text{hdepth } M^$.*

Proof. Fix a d -manifold M and set $c = \text{cdepth } M$, $h = \text{hdepth } M$. Since M is a manifold, all links inside M are homology spheres or homology balls. By Lemma 4.27 and the Morse inequalities, all homology groups of M vanish up to the h -th one (and possibly even further). So $\text{adepth } M \geq h$ by Definition 4.1. Analogously, from Corollary 3.4 we get that $\text{adepth } M \geq c$. The inequalities $1 \leq c$, $1 \leq h$ and $\text{adepth } M \leq d$ are obvious. By Lemma 4.27, if $h \geq 2$, then M is 1-connected. The same holds if $c \geq 2$, but the proof is non-trivial; see Lemma 3.7. This settles (i). Simply connected manifolds are orientable. Item (ii) is then a direct consequence of Lemma 4.27. (If $\partial M = \emptyset$ the polarity principle [25, Theorem 4.6] and Forman’s sphere theorem (Theorem 3.8) imply that M is an endo-collapsible sphere.) Finally, item (iii) is a re-wording of our Ball Theorem 3.12 and item (iv) is a corollary of Theorem 3.10. \square

Remark 4.29. Theorem 4.28 does not extend to pseudo-manifolds. In fact, a pinched annulus has maximal collapse depth without being Cohen–Macaulay or simply connected. Moreover, not all simply connected triangulated manifolds have $\text{cdepth} \geq 2$. In fact, for each $d \geq 3$ the author and Ziegler constructed a PL d -sphere S with

$\text{cdepth } S = 1$ [8]. (See also Theorem 4.18.) The dual block decomposition of this S yields a d -sphere S^* with $\text{hdepth } S = 1$.

Corollary 4.30. *Let $d \geq 3$ be an integer. Let H be a manifold that is a homology d -pseudo-sphere but not a sphere. Then $\text{cdepth } H = \text{hdepth } H = 1$ and $\text{adepth } H = \dim H = d$.*

Proof. Since the algebraic depth does not distinguish between spheres and homology spheres, H is Cohen–Macaulay. Were H simply connected, by the Poincaré conjecture H would be a sphere, a contradiction. So H is not 1-connected. By Theorem 4.28, item (i), both the collapse depth of H and the hamiltonian depth of H are smaller than two. \square

Corollary 4.31. *For each d even, $d > 1$, there exists a d -manifold M for which*

$$\text{cdepth } M = \text{adepth } M = \text{hdepth } M = \frac{d}{2}.$$

Proof. Let S_k be the boundary of the $(k+1)$ -simplex (or of the $(k+1)$ -cube). Since S_k is endo-collapsible, by [5, Proposition 2.3] the polytopal complex $S_k \times S_k$, after the removal of a facet, collapses onto two copies of S_k glued together at a single vertex. This implies $\text{cdepth}(S_k \times S_k) \geq k$.

Also $\text{hdepth}(S_k \times S_k) \geq k$. To see this, let H be the k -complex obtained by removing a facet from S_k . Let us consider the product complex $H \times H$ as a subcomplex of $S_k \times S_k$. Since H is $(k-1)$ -hamiltonian and collapsible, $H \times H$ is still $(k-1)$ -hamiltonian and collapsible. Let us fix a collapsing sequence for $H \times H$. Let C be the k -complex obtained by removing from $H \times H$ all collapse-pairs (σ, Σ) , with $\dim \sigma \geq k$. Being an intermediate step in the collapse of $H \times H$, the complex C is collapsible. Moreover, C is a k -subcomplex of $S_k \times S_k$ that still contains all of the $(k-1)$ -faces of $S_k \times S_k$. So, $\text{hdepth}(S_k \times S_k) \geq k$.

However, $S_k \times S_k$ is not k -connected, as the k -th homology group of $S_k \times S_k$ is $\mathbb{Z} \oplus \mathbb{Z}$. Therefore, $\text{adepth}(S_k \times S_k) < k + 1$. In view of Theorem 4.28, this implies that $\text{adepth}(S_k \times S_k) = \text{hdepth}(S_k \times S_k) = \text{cdepth}(S_k \times S_k) = k$, while $\dim(S_k \times S_k) = 2k$. \square

Corollary 4.32. *For $d \geq 3$, no d -ball, no d -sphere and no PL d -manifold without boundary has collapse depth $d - 1$.*

Proof. If S is a sphere (not necessarily PL) and $\text{cdepth } S \geq d - 1$, then S minus a facet collapses onto a contractible 1-complex C . Since all contractible 1-complexes are collapsible, $\text{cdepth } S = d$. Similarly, if B is a ball and $\text{cdepth } B \geq d - 1$, then B minus a facet collapses onto the union of ∂B with some trees. Therefore, B minus a facet can be collapsed onto ∂B .

Now, let M be a PL manifold *without boundary*. If $\text{cdepth } M \geq d - 1$, by Theorem 4.28, part (iv), we can say that M is $(d - 2)$ -connected. Every $(d - 2)$ -connected manifold without boundary M is a homotopy sphere. In fact, via Poincaré duality and the Universal Coefficient Theorem for cohomology one can show that $\pi_{d-1}(M) = H_{d-1}(M) = 0$ and $\pi_d(M) = H_d(M) = \mathbb{Z}$. By the Poincaré conjecture, M is a sphere, and we are back in a previously studied case. \square

In contrast, some PL d -manifolds with boundary are $(d - 2)$ -connected but not $(d - 1)$ -connected. In fact, Corollary 4.32 does not extend to manifolds with boundary: A $3 \times 3 \times 3$ pile of cubes with the central cube removed yields a 3-manifold with collapse depth two.

Collapse depth and hamiltonian depth may be arbitrarily far apart from the algebraic depth, as shown in Remark 4.29. The next proposition shows that collapse depth and hamiltonian depth may also be arbitrarily far apart from one another:

Proposition 4.33. *For each $d \geq 3$, there is a PL d -ball B with $\text{cdepth } B = 1$ and $\text{hdepth } B = \text{adepth } B = d$.*

Proof. It suffices to prove the claim for $d = 3$. In fact, given a d -ball B and a new vertex v , we have $\text{cdepth}(v * B) = \text{cdepth}(B)$ by Theorem 3.19 and $\text{hdepth}(v * B) = d + 1$ by Theorem 4.9, item (i). Now, take a collapsible 3-ball B with a knotted spanning edge. By Corollary 4.21, $\text{cdepth } B < 3$; by Corollary 4.32, $\text{cdepth } B \neq 2$. Thus $\text{cdepth } B = 1$. However, $\text{hdepth } B = \dim B = 3$ because B is collapsible. \square

In the paper [6] we show how the collapse depth of a manifold is deeply related to its geometrical connectivity, introduced by Wall [71]. We conclude the present work with a hierarchy of some of the properties we studied so far:

Theorem 4.34. *For d -manifolds ($d \geq 2$),*

$\text{shellable} \implies \text{constructible} \implies \text{endo-collapsible} \implies \text{LC} \implies \text{simply connected}$

and $\text{endo-collapsible} \implies \text{Cohen-Macaulay}$. For $d \geq 3$, all these implications are strict. However, LC 3-manifolds without boundary and endo-collapsible 3-manifolds without boundary are the same.

Proof. All shellable complexes are constructible. Constructible manifolds are endo-collapsible by Theorem 4.1. To show that endo-collapsible manifolds are Cohen-Macaulay, use either Theorem 4.28 or the Ball Theorem and the Sphere Theorem. The implication “endo-collapsible \implies LC” is a direct consequence of Theorem 3.5. Finally, LC manifolds are simply connected by Lemma 3.7.

As far as the strictness is concerned, Theorem 4.9 allows us to restrict ourselves to the case $d = 3$. A non-shellable constructible 3-ball with only 18 facets is presented by Lutz in [48]. Any homology 3-sphere is Cohen-Macaulay, but it cannot be endo-collapsible; cf. Corollary 4.30. Examples of non-constructible endo-collapsible 3-spheres are given by Corollary 4.21. For 3-manifolds without boundary, the endo-collapsible notion coincides with the LC one. This follows directly from Corollary 4.32. In contrast, some manifolds with boundary are LC but not endo-collapsible. For example, the cubical complex given by a $3 \times 3 \times 3$ pile of cubes without the central one is LC and not endo-collapsible, because the removal of a cube makes it collapsible onto its boundary plus an edge. \square

ACKNOWLEDGMENTS

The author is very grateful to Karim Adiprasito, Eric Babson, Anders Björner, Francesco Cavazzani, Alex Engström, Rob Kirby, Ed Swartz and Günter Ziegler for useful discussions, suggestions and references. Thanks to María Angélica Cueto for reading the Introduction. Many thanks also to MSRI, the Centro De Giorgi and the Berlin Mathematical School for hospitality and funding during this project. Finally, the author wishes to thank the anonymous referees for the careful and detailed review.
