# HEEGNER POINTS ON MODULAR CURVES 

LI CAI, YIHUA CHEN, AND YU LIU

#### Abstract

In this paper, we study the Heegner points on more general modular curves other than $X_{0}(N)$, which generalizes Gross' work "Heegner points on $X_{0}(N)$ ". The explicit Gross-Zagier formula and the Euler system property are stated in this case. Using such a kind of Heegner points, we construct certain families of quadratic twists of $X_{0}(36)$, with the ranks of Mordell-Weil groups being zero and one respectively, and show that the 2-part of their BSD conjectures hold.

## 1. Introduction

Let $\phi=\sum_{n=1}^{\infty} a_{n} q^{n}$ be a newform of weight 2 , level $\Gamma_{0}(N)$, normalized such that $a_{1}=1$. Let $K$ be an imaginary quadratic field of discriminant $D$ and $\chi$ a (primitive) ring class character over $K$ of conductor $c$, i.e., a character of $\operatorname{Pic}\left(\mathcal{O}_{c}\right)$ where $\mathcal{O}_{c}$ is the order $\mathbb{Z}+c \mathcal{O}_{K}$ of $K$. Let $L(s, \phi, \chi)$ be the Rankin-Selberg convolution of $\phi$ and $\chi$. Assume the Heegner condition:
(1) $(c, N)=1$.
(2) Any prime $p \mid N$ is either split in $K$ or ramified in $K$ with $\operatorname{ord}_{p}(N)=1$ and $\chi([\mathfrak{p}]) \neq a_{p}$, where $\mathfrak{p}$ is the unique prime ideal of $\mathcal{O}_{K}$ above $p$ and $[\mathfrak{p}]$ is its class in $\operatorname{Pic}\left(\mathcal{O}_{c}\right)$.
Under this condition, the sign of $L(s, \phi, \chi)$ is -1 and Gross studies the Heegner points on $X_{0}(N)$ in [7. It's well known that $X_{0}(N)(\mathbb{C})$ parameterizes the pairs $(E, C)$, with $E$ an elliptic curve over $\mathbb{C}$ and $C$ a cyclic subgroup of $E$ of order $N$. By the Heegner condition, there exists a proper ideal $\mathcal{N}$ of $\mathcal{O}_{c}$ such that $\mathcal{O}_{c} / \mathcal{N} \cong$ $\mathbb{Z} / N \mathbb{Z}$. For any proper ideal $\mathfrak{a}$ of $\mathcal{O}_{c}$, let $P_{\mathfrak{a}} \in X_{0}(N)$ be the point representing $\left(\mathbb{C} / \mathfrak{a}, \mathfrak{a} \mathcal{N}^{-1} / \mathfrak{a}\right)$, which is defined over the ring class field $H_{c}$, the abelian extension of $K$ with Galois group $\operatorname{Pic}\left(\mathcal{O}_{c}\right)$ given by class field theory. Such points are called Heegner points over $K$ of conductor $c$ and only depend on the class of $\mathfrak{a}$ in $\operatorname{Pic}\left(\mathcal{O}_{c}\right)$.

[^0]Let $J_{0}(N)$ be the Jacobian of $X_{0}(N)$. The cusp [ $\infty$ ] on $X_{0}(N)$ defines a morphism over $\mathbb{Q}$ from $X_{0}(N)$ to $J_{0}(N)$ given by $P \mapsto[P-\infty]$. Let $P_{\chi}$ be the point

$$
P_{\chi}=\sum_{[\mathfrak{a}] \in \operatorname{Pic}\left(\mathcal{O}_{c}\right)}\left[P_{\mathfrak{a}}-\infty\right] \otimes \chi([\mathfrak{a}]) \in J_{0}(N)\left(H_{c}\right) \otimes_{\mathbb{Z}} \mathbb{C}
$$

and let $P_{\chi}^{\phi}$ be the $\phi$-isotypical component of $P_{\chi}$. Under the Heegner condition, Cai-Shu-Tian [3] give an explicit form of Gross-Zagier formula which relates the height of $P_{\chi}^{\phi}$ to $L^{\prime}(1, \phi, \chi)$. In fact, they give an explicit form of Gross-Zagier formula in the general Shimura curve case.

Let the data $(\phi, K, \chi)$ be as above, and generalize the Heegner condition to the following one $(*)$ :
(i) $(c, N)=1$,
(ii) if a prime $p \mid N$ is inert in $K$, then $\operatorname{ord}_{p} N$ is even; if $p \mid N$ is ramified in $K$, then $\operatorname{ord}_{p} N=1$ and $\chi([\mathfrak{p}]) \neq a_{p}$, where $\mathfrak{p}$ is the unique prime ideal of $\mathcal{O}_{K}$ above $p$ and $[\mathfrak{p}]$ is its class in $\operatorname{Pic}\left(\mathcal{O}_{c}\right)$.
Under these assumptions, we can write $N=N_{0} N_{1}^{2}$, with $p \mid N_{1}$ if and only if $p$ is inert. Given an embedding $K \hookrightarrow M_{2}(\mathbb{Q})$ such that $K \cap M_{2}(\mathbb{Z})=K \cap R_{0}\left(N_{0}\right)=\mathcal{O}_{c}$, where

$$
R_{0}\left(N_{0}\right)=\left\{A \in M_{2}(\mathbb{Z}) \left\lvert\, A \equiv\left(\begin{array}{cc}
* & * \\
0 & *
\end{array}\right)\left(\bmod N_{0}\right)\right.\right\}
$$

We will consider the order $R$ of $M_{2}(\mathbb{Z})$ given by $R=\mathcal{O}_{c}+N_{1} R_{0}\left(N_{0}\right)$. Define

$$
\Gamma_{K}(N)=R^{\times} \cap \mathrm{SL}_{2}(\mathbb{Z})=\left\{\begin{array}{l|l}
A \in \mathrm{SL}_{2}(\mathbb{Z}) & \begin{array}{l}
A \equiv\left(\begin{array}{cc}
* & * \\
0 & *
\end{array}\right)\left(\bmod N_{0}\right) \\
A \bmod N_{1} \in R / N_{1} R
\end{array}
\end{array}\right\}
$$

Now we have to consider the modular curve $X_{K}(N)=\Gamma_{K}(N) \backslash \mathscr{H} \cup\{$ cusps $\}$, where $\mathscr{H}=\{z \in \mathbb{C}: \operatorname{Im}(z)>0\}$.

This modular curve is not the usual modular curve of the form $X_{0}(M)$ any longer, if $N_{1} \neq 1 . X_{K}(N)$ parameterizes $(E, C, \alpha)$ where $E$ is an elliptic curve over $\mathbb{C}, C$ is a cyclic subgroup of $E$ of order $N_{0}$ and $\alpha$ is an $H$-orbit of an isomorphism $\left(\mathbb{Z} / N_{1} \mathbb{Z}\right)^{2} \simeq E\left[N_{1}\right]$, where

$$
H=\left(\mathcal{O}_{K} / N_{1} \mathcal{O}_{K}\right)^{\times} \subset \mathrm{GL}_{2}\left(\mathbb{Z} / N_{1} \mathbb{Z}\right)
$$

The readers are referred to [9] theorem 7.1.3. Let $h_{0}$ be the fixed point of $\mathscr{H}$ under the action of $K^{\times}$. Note that since $\mathbb{Z}+\mathbb{Z} h_{0}^{-1}$ is an invertible ideal of $\mathcal{O}_{c}$, then the triple $P=\left(\mathbb{C} / \mathbb{Z}+\mathbb{Z} h_{0},\left\langle\frac{1}{N_{0}}\right\rangle, H\binom{\frac{h_{0}}{N_{1}}}{\frac{1}{N_{1}}}\right)$ is a Heegner point on $X_{K}(N)$ in the sense of Definition 2.2. By CM theory, $P \in X_{K}(N)\left(K^{\mathrm{ab}}\right)$. The conductor of $P$ is also defined to be $c$, the conductor of $\mathcal{O}_{c}$. For details, see Section 2.

Assume $\phi$ corresponds to an elliptic curve $E / \mathbb{Q}$, by modularity of elliptic curves, Jacquet-Langlands correspondence and [27, Theorem 3.8], there is a modular parametrization $f: X_{K}(N) \rightarrow E$, taking $[\infty]$ to identity in $E$. It is unique in the sense that given two parametrizations $f_{1}, f_{2}$, there exist integers $n_{1}, n_{2}$ such that $n_{1} f_{2}=n_{2} f_{2}$ [3, Proposition 3.8]. Now we can formulate the following GrossZagier formula:
Theorem 1.1 ([3]). Under the assumption (*)

$$
\begin{equation*}
L^{\prime}(1, E, \chi)=2^{-\mu(N, D)} \cdot \frac{8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(N)}}{u^{2} c \sqrt{\left|D_{K}\right|}} \frac{\widehat{h}_{K}\left(P_{\chi}(f)\right)}{\operatorname{deg} f} \tag{GZ}
\end{equation*}
$$

where $(,)_{\Gamma_{0}(N)}$ is the Petersson inner product, $\hat{h}_{K}$ is the Néron-Tate height over $K, \mu(N, D)$ is the number of prime factors of $(N, D), u=\left[\mathcal{O}_{c}^{\times}:\{ \pm 1\}\right]$.

As an application of such a kind of parametrization, we will construct a family of quadratic twists of an elliptic curve with Mordell-Weil groups of rank one. The action of complex conjugation on the CM-points of the modular curve is a crucial point in the proof of the nontriviality of the Heegner point. For the usual modular curve $X_{0}(N)$, complex conjugation is essentially the Atkin-Lehner operator. However, it does not hold for the modular curve $X_{K}(N)$. We will find that the action of complex conjugation is given in terms of a combination of local Atkin-Lehner operators and the nontrivial normalizer of $K^{\times}$in $\mathrm{GL}_{2}(\mathbb{Q})$. Denote this operator by $w$. Then $f+f^{w}$ is a constant map with its image a nontrivial 2 -torsion point; see Lemma 3.8. This phenomenon and the norm compatible relation control the divisibility of Heegner cycles. Together with the Gross-Zagier formula, the divisibility of Heegner cycles implies the 2-part of the BSD conjecture for our family of quadratic twists.

For each square free nonzero integer $d \neq 1$, we write $E^{(d)}$ for the twist of an elliptic curve $E / \mathbb{Q}$ by the quadratic extension $\mathbb{Q}(\sqrt{d}) / \mathbb{Q}$. The results of [26], [2], [5], 14] show that there are infinitely many $d$ such that $L\left(E^{(d)}, s\right)$ is nonvanishing at $s=1$, and infinitely many $d$ such that $L\left(E^{(d)}, s\right)$ has a simple zero at $s=1$.

The work of [21], [22] for the elliptic curve $\left(X_{0}(32),[\infty]\right): y^{2}=x^{3}-x$ constructs explicitly families of $d$ with $\operatorname{ord}_{s=1} L\left(E^{(d)}, s\right)=1$. The work of 4] deals with the elliptic curve $E=\left(X_{0}(49),[\infty]\right)$ which has CM by $\sqrt{-7}$, gets similar results to [21].

Here, we construct a family of quadratic twists of $E=\left(X_{0}(36),[\infty]\right)$ such that the ranks of the Mordell-Weil groups for these twists are one. In this paper, we have made a new argument different from [4, [21] and [22, which is much shorter and simpler. The new argument relies on a norm compatible relation between Heegner points of different conductors. See Theorem 2.15

Theorem 1.2. Let $\ell$ be a prime such that 3 is split in $\mathbb{Q}(\sqrt{-\ell})$ and 2 is unramified in $\mathbb{Q}(\sqrt{-\ell})$. Let $M=q_{1} \cdots q_{r}$ be a positive square-free integer with prime factors $q_{i}$ all inert in $\mathbb{Q}(\sqrt{-3}), q_{i} \equiv 1(\bmod 4)$ and $q_{i}$ inert in $\mathbb{Q}(\sqrt{-\ell})$. Then
(1) $\operatorname{ord}_{s=1} L\left(s, E^{(-\ell M)}\right)=1=\operatorname{rank} E^{(-\ell M)}(\mathbb{Q})$;
(2) $\# Ш\left(E^{(-\ell M)} / \mathbb{Q}\right)$ is odd, and the p-part of the full BSD conjecture of $E^{(-\ell M)}$ holds for $p \nmid 3 \ell M$, i.e.,
$\operatorname{ord}_{p}\left(\frac{L^{\prime}\left(E^{(-\ell M)}\right)}{\Omega\left(E^{(-\ell M)}\right) \operatorname{Reg}\left(E^{(-\ell M)}\right)}\right)=\operatorname{ord}_{p}\left(\frac{\# Ш\left(E^{(-\ell M)}\right)}{\prod_{q<\infty} c_{q}\left(E^{(-\ell M)}\right)\left(\# E^{(-\ell M)}(\mathbb{Q})_{\text {tor }}\right)^{2}}\right)$.
The nontriviality of Heegner cycles and Gross-Zagier formula also imply the rank part of BSD conjecture for $E^{(M)}$, namely,

$$
\operatorname{ord}_{s=1} L\left(s, E^{(M)}\right)=0=\operatorname{rank} E^{(M)}(\mathbb{Q}) .
$$

We are also interested in the full BSD conjecture for $E^{(M)}$. In fact, the part (2) of Theorem 1.2 depends on the similar assertion for $E^{(M)}$, which is the part (2) of Theorem 1.3

A new feature of this paper is that we give a parallel proof of the BSD conjecture for $E^{(M)}$ as we have mentioned above, that is, using the Waldspurger formula and the norm property of Gross points. For the induction method used in [4], [23], there is an embedding problem of imaginary quadratic fields to quaternion algebras
which is related to the problem of representing integers by ternary quadratic forms (see also the argument before [4, Definition 5.5], [23, Section 2.1] and [13). The use of the norm compatible property of Gross points avoids this embedding problem.

If, for the data $(\phi, K, \chi)$, the root number $\epsilon(\phi, \chi)$ equals +1 , by [3] we can choose an appropriate definite quaternion algebra $B$ over $\mathbb{Q}$ containing $K$, an order $R$ of $B$ of discriminant $N$ with $R \cap K=\mathcal{O}_{K}$ and a "unique" function $f: B^{\times} \backslash \widehat{B}^{\times} / \widehat{R}^{\times} \rightarrow \mathbb{C}$. Assume the conductor $c$ of $\chi$ satisfies $(c, N)=1$. Let $x_{c} \in K^{\times} \backslash \widehat{B}^{\times} / \widehat{R}^{\times}$be a Gross point of conductor $c$, that is, $x_{c}$ satisfies that $x_{c} \widehat{R} x_{c}^{-1} \cap \widehat{K}=\widehat{\mathcal{O}}_{c}$. Denote by

$$
P_{\chi}(f)=\sum_{\sigma \in \operatorname{Gal}\left(H_{c} / K\right)} f\left(\sigma \cdot x_{c}\right) \chi(\sigma) .
$$

Then with similar notation as for Gross-Zagier formula, we have the Waldspurger formula (see Theorem [2.16)

$$
L(1, E, \chi)=2^{-\mu(N, D)} \cdot \frac{8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(N)}}{u^{2} \sqrt{\left|D c^{2}\right|}} \cdot \frac{\left|P_{\chi}(f)\right|^{2}}{\langle f, f\rangle}
$$

Moreover, the Gross points of different conductors also form an "Euler system" (see Section 2). The following theorem can be viewed as the rank zero version of Theorem 1.2

Theorem 1.3. Let $M=q_{1} \cdots q_{r}$ be a positive square-free integer with prime factors $q_{i}$ all inert in $\mathbb{Q}(\sqrt{-3})$ and $q_{i} \equiv 1(\bmod 4)$; then
(1) $\operatorname{ord}_{s=1} L\left(s, E^{(M)}\right)=0=\operatorname{rank} E^{(M)}(\mathbb{Q})$;
(2) $\# \amalg\left(E^{(M)} / \mathbb{Q}\right)$ is odd, and the p-part of the full BSD conjecture of $E^{(-\ell M)}$ holds for $p \neq 3$.

## 2. The modular curve and Heegner points

2.1. The modular curve $X_{K}(N)$. Let $K$ be an imaginary quadratic field with discriminant $D$. Let $N=N_{0} N_{1}^{2}$ be a positive integer such that $p \mid N_{1}$ if and only if $p$ is inert in $K$. Let $c$ be another positive integer coprime to $N$. Take an embedding $K \hookrightarrow M_{2}(\mathbb{Q})$ which is admissible in the sense that

$$
K \cap M_{2}(\mathbb{Z})=K \cap R_{0}\left(N_{0}\right)=\mathcal{O}_{c}
$$

Let $R$ be the order of $M_{2}(\mathbb{Z})$ given by $R=\mathcal{O}_{c}+N_{1} R_{0}\left(N_{0}\right)$. Then $R$ has discriminant $N$ with $R \cap K=\mathcal{O}_{c}$.

Let $\Gamma_{K}(N)=R^{\times} \cap \mathrm{SL}_{2}(\mathbb{Z})$ and $X_{K}(N)$ be the modular curve over $\mathbb{Q}$ with level $\Gamma_{K}(N)$. It's well known that $X\left(N_{0} N_{1}\right)(\mathbb{C})$ parameterizes $\left(E,\left(\mathbb{Z} / N_{0} N_{1}\right)^{2} \simeq\right.$ $\left.E\left[N_{0} N_{1}\right]\right)$ ) where $E$ is an elliptic curve over $\mathbb{C}$. By $\underline{9}$ chapter 3.5, it parameterizes $\left.\left(E,\left(\mathbb{Z} / N_{0}\right)^{2} \simeq E\left[N_{0}\right],\left(\mathbb{Z} / N_{1}\right)^{2} \simeq E\left[N_{1}\right]\right)\right)$. Then by [9] chapter $7, X_{K}(N)$ parameterizes $\left.\left(E, C, \alpha:\left(\mathbb{Z} / N_{1}\right)^{2} \simeq E\left[N_{1}\right]\right)\right)$, where $C$ is a cyclic subgroup of $E\left[N_{0}\right]$ of order $N_{0}$, and $\alpha$ is an $H$-orbit of a basis of $E\left[N_{1}\right]$ where $H:=\left(\mathcal{O}_{K} / N_{1} \mathcal{O}_{K}\right)^{\times} \subset$ $\mathrm{GL}_{2}\left(\mathbb{Z} / N_{1} \mathbb{Z}\right)$. Precisely, the class of $z \in \mathscr{H}$ in $X_{K}(N)$ corresponds to the triple

$$
\left(\mathbb{C} / \mathbb{Z} \cdot z+\mathbb{Z},\left\langle\frac{1}{N_{0}}\right\rangle, H\binom{\frac{z}{N_{1}}}{\frac{1}{N_{1}}}\right) .
$$

Recall that $h_{0}=\mathscr{H}^{K^{\times}}$. For $X$ a field, a quaternion algebra over $\mathbb{Q}$ (the situations involved in this paper), or an order in them, we denote $\widehat{X}=X \otimes_{\mathbb{Z}} \prod_{\ell<\infty} \mathbb{Z}_{\ell}$.

Lemma 2.1. If $m$ is a positive integer and $\left(m, c N D_{K}\right)=1$, then for any invertible fractional ideals $\mathfrak{a}, \mathcal{N}$ of $\mathcal{O}_{c m}$, satisfying $\mathcal{N}^{-1} \mathfrak{a} / \mathfrak{a} \simeq \mathbb{Z} / N_{0} \mathbb{Z}$, there exist a $\mathbb{Z}$-basis $\{u, v\}$ of $\mathfrak{a}$ and $g \in \mathrm{GL}_{2}^{+}(\mathbb{Q})$, such that $\mathcal{N}^{-1} \mathfrak{a}=\mathbb{Z} \frac{u}{N_{0}}+\mathbb{Z} v, \frac{v}{u}=g^{-1} h_{0}$, and $K \cap g R g^{-1}=\mathcal{O}_{c m}$.

Proof. Consider the natural projection between curves over $\mathbb{Q}: X_{K}(N) \rightarrow X_{0}\left(N_{0}\right)$, which is the forgetful functor in the moduli aspect $(E, C,[\alpha]) \mapsto(E, C)$. $\mathfrak{a}, \mathcal{N}$ define a Heegner point $\left(\mathbb{C} / \mathfrak{a}, \mathcal{N}^{-1} \mathfrak{a} / \mathfrak{a}\right)$ on $X_{0}\left(N_{0}\right)$. Then there exists a $\mathbb{Z}$-basis $\{u, v\}$ of $\mathfrak{a}$ and $g=\left(\begin{array}{ll}a & b \\ c & d\end{array}\right) \in \mathrm{GL}_{2}^{+}(\mathbb{Q})$, such that $\mathcal{N}^{-1} \mathfrak{a}=\mathbb{Z}\left\langle\frac{u}{N_{0}}, v\right\rangle, \frac{v}{u}=g^{-1} h_{0}$, and $K \cap g \widehat{R_{0}\left(N_{0}\right)} g^{-1}=\mathcal{O}_{c m}$. If we choose another basis, $g$ will differ by an element in $\Gamma_{0}\left(N_{0}\right)$ on the right and an element in $K^{\times}$on the left. So we have to prove there exists $g^{\prime} \in \Gamma_{0}\left(N_{0}\right)$, such that $K \cap g g^{\prime} \widehat{R} g^{\prime-1} g^{-1}=\mathcal{O}_{c m}$.

Denote by $\mathcal{O}^{\prime}=g^{-1} \mathcal{O}_{c m} g$, it suffices to prove that there exists $g^{\prime} \in \Gamma_{0}\left(N_{0}\right)$, such that for any $\ell \mid N_{1}, \mathcal{O}_{\ell}^{\prime} \subset g^{\prime} R_{\ell} g^{\prime-1}$. In fact, if it holds, then

$$
\mathcal{O}_{\ell}^{\prime} \subset g^{-1} K_{\ell} g \cap g^{\prime} R_{\ell} g^{\prime-1}
$$

hence they are equal, since $\mathcal{O}_{\ell}^{\prime}$ is the maximal compact subring of $g^{-1} K_{\ell} g$. This implies that $\mathcal{O}^{\prime}=g^{-1} K g \cap g^{\prime} \widehat{R} g^{\prime-1}$. i.e., $K \cap g g^{\prime} \widehat{R} g^{\prime-1} g^{-1}=\mathcal{O}_{c m}$.

Note that $\mathcal{O}_{\ell} \subset R_{\ell}$, by Lemma [2.7, there exists a $g_{\ell} \in \mathrm{SL}_{2}\left(\mathbb{Z}_{\ell}\right)$, such that $\mathcal{O}_{\ell}^{\prime}=g_{\ell} \mathcal{O}_{\ell} g_{\ell}^{-1}$. By Lemma 2.9, there exists a $g^{\prime} \in \Gamma_{0}\left(N_{0}\right)$, such that

$$
g^{\prime} \equiv g_{\ell}\left(\bmod \ell^{\operatorname{ord}_{\ell} N_{1}}\right) \forall \ell \mid N_{1} .
$$

Let $\beta: M_{2}\left(\mathbb{Z}_{\ell}\right) \rightarrow M_{2}\left(\mathbb{Z}_{\ell} / N_{1} \mathbb{Z}_{\ell}\right)$, be the natural projection. We see that $g^{\prime} R_{\ell} g^{\prime-1}=$ $\beta^{-1}\left(\beta\left(\mathcal{O}_{\ell}^{\prime}\right)\right)$. This induces $\mathcal{O}_{\ell}^{\prime} \subset g^{\prime} R_{\ell} g^{\prime-1}$.

Definition 2.2. Let $\mathfrak{a}, \mathcal{N}$ and $u, v, g$ be as in Lemma 2.1] A Heegner point on $X_{K}(N)$ of conductor cm is a triple

$$
P=\left(\mathbb{C} / \mathfrak{a}, \mathcal{N}^{-1} \mathfrak{a} / \mathfrak{a}, H\binom{\frac{v}{N_{1}}}{\frac{u}{N_{1}}}\right) .
$$

Remark 2.3. This point corresponds to the point $\frac{v}{u} \in \mathscr{H}$.
The order $\mathcal{O}_{c}$ is of the form $\mathbb{Z}+\mathbb{Z} \varpi_{c}$ where $\varpi_{c}=\frac{c D+c \sqrt{D}}{2}$. Denote by $\left(\begin{array}{cc}x & y \\ z & w\end{array}\right) \in$ $\mathrm{GL}_{2}(\mathbb{Q})$ the image of $\varpi_{c}$ under the fixed embedding $K \hookrightarrow M_{2}(\mathbb{Q})$. Since $K$ is a field, $y z \neq 0$.

Lemma 2.4. $K=\mathbb{Q}+\mathbb{Q} h_{0}$ and $\mathcal{O}_{c}=\mathbb{Z}+\mathbb{Z} y h_{0}^{-1}$.
Proof. We have $x+w=D c, x w-y z=\frac{c^{2}\left(D^{2}-D\right)}{4}$. As $h_{0}$ is fixed by $\left(\begin{array}{cc}x & y \\ z & w\end{array}\right)$,

$$
\frac{x h_{0}+y}{z h_{0}+w}=h_{0} \quad \text { and } \quad z h_{0}^{2}+(w-x) h_{0}-y=0 .
$$

Hence

$$
h_{0}=\frac{(x-w)+c \sqrt{D}}{2 z} \in K \backslash \mathbb{Q} \quad \text { and } \quad h_{0}^{-1}=\frac{2 z}{(x-w)+c \sqrt{D}}=\frac{(x-w)-c \sqrt{D}}{2 y},
$$

so

$$
y h_{0}^{-1}=-w+\frac{D c+c \sqrt{D}}{2}
$$

Lemma 2.5. Let $\mathfrak{a}=\mathbb{Z}+\mathbb{Z} \cdot h_{0}^{-1}$ and $\mathcal{N}^{-1}=\mathbb{Z}+\mathbb{Z} \cdot N_{0}^{-1} h_{0}^{-1}$. Then $\operatorname{End}(\mathfrak{a}):=$ $\{x \in K: x \mathfrak{a} \subset \mathfrak{a}\}=\mathcal{O}_{c}$, and $\operatorname{End}\left(\mathcal{N}^{-1}\right)=\mathcal{O}_{c}$.
Proof. Let $\left(a+b h_{0}^{-1}\right) \mathfrak{a} \subset \mathfrak{a}$. It is equivalent to that

$$
\left(a+b h_{0}^{-1}\right) \in \mathfrak{a} \quad \text { and } \quad\left(a+b h_{0}^{-1}\right) h_{0}^{-1} \in \mathfrak{a} .
$$

The first condition implies $a, b \in \mathbb{Z}$; then the second one is equivalent to $b h_{0}^{-2} \in \mathfrak{a}$. But

$$
b h_{0}^{-2}=y^{-1} b\left((w-x) h_{0}^{-1}+z\right) \in \mathfrak{a} .
$$

The condition $R \cap K=\mathcal{O}_{c}$ tells $(w-x, z, y)=1$, so the above condition implies $b \in y \mathbb{Z}$, which tells us that $\operatorname{End}(\mathfrak{a})=\mathcal{O}_{c}$. The assertion for $\mathcal{N}^{-1}$ is similar, noticing that $N_{0} \mid z$.

Clearly, $\mathfrak{a}$ and $\mathcal{N}$ are invertible ideals of $\mathcal{O}_{c}$, and $\mathcal{N}^{-1} / \mathfrak{a} \simeq \mathbb{Z} / N_{0} \mathbb{Z}$. Summing up:
Proposition 2.6. Let $K \hookrightarrow M_{2}(\mathbb{Q})$ be an admissible embedding and $h_{0} \in \mathcal{H}^{K^{\times}}$. Denote by $\mathfrak{a}=\mathbb{Z}+\mathbb{Z} \cdot h_{0}^{-1}$ and $\mathcal{N}^{-1}=\mathbb{Z}+\mathbb{Z} \cdot N_{0}^{-1} h_{0}^{-1}$; then

$$
P=\left(\mathbb{C} / \mathfrak{a}, \mathcal{N}^{-1} / \mathfrak{a}, H\binom{\frac{y}{N_{1}}}{\frac{y h_{0}^{-1}}{N_{1}}}\right)
$$

is a Heegner point on $X_{K}(N)$ of conductor $c$.
Now we prove lemmas needed in Lemma 2.1.
Lemma 2.7. For any two embeddings $\varphi_{i}: \mathbb{Z}_{p^{2}} \rightarrow M_{2}\left(\mathbb{Z}_{p}\right), i=1,2$, there exists $g \in \mathrm{SL}_{2}\left(\mathbb{Z}_{p}\right)$, such that $\varphi_{1}=g^{-1} \varphi_{2} g$.

Remark 2.8. If we change $\mathbb{Z}_{p}$ to $\mathbb{Q}_{p}, \mathbb{Z}_{p^{2}}$ to $\mathbb{Q}_{p^{2}}$ and $\mathrm{SL}_{2}$ to $\mathrm{GL}_{2}$, this lemma is well-known as a consequence of Noether-Skolem theorem.

Proof. Consider $V=\mathbb{Z}_{p} \oplus \mathbb{Z}_{p}$, with the natural action of $M_{2}\left(\mathbb{Z}_{p}\right)$. Via $\varphi_{i}$, we view $V$ as a $\mathbb{Z}_{p^{2}}$-module, denoted by $V_{i}, i=1,2$. Since $\mathbb{Z}_{p^{2}}$ is a discrete valuation ring and $V_{i}$ are torsion free, both $V_{1}, V_{2}$ are free $\mathbb{Z}_{p^{2}}$-modules of rank one. So there exists an isomorphism $g_{0}: V_{1} \rightarrow V_{2}$ of $\mathbb{Z}_{p^{2}}$-modules, this isomorphism corresponds to an element of $\mathrm{GL}_{2}\left(\mathbb{Z}_{p}\right)$, also denoted by $g_{0}$. The fact $g_{0}$ is an isomorphism of $\mathbb{Z}_{p^{2}}$-modules means that

$$
g_{0} \varphi_{1}(x)=\varphi_{2}(x) g_{0} \forall x \in \mathbb{Z}_{p^{2}}
$$

Note that $\mathrm{N}_{\mathbb{Z}_{p^{2}} / \mathbb{Z}_{p}} \mathbb{Z}_{p^{2}}^{\times}=\mathbb{Z}_{p}^{\times}$, choose $t \in \mathbb{Z}_{p^{2}}^{\times}$, such that $\mathrm{N}_{\mathbb{Z}_{p^{2}} / \mathbb{Z}_{p}} t=\left(\operatorname{det} g_{0}\right)^{-1}$, i.e., $\operatorname{det} \varphi_{1}(t)=\left(\operatorname{det} g_{0}\right)^{-1}$. Therefore

$$
g_{0} \varphi_{1}(t) \varphi_{1}(x)=g_{0} \varphi_{1}(x) \varphi_{1}(t)=\varphi_{2}(x) g_{0} \varphi_{1}(t)
$$

So $g=g_{0} \varphi_{1}(t) \in \mathrm{SL}_{2}\left(\mathbb{Z}_{p}\right)$ is the desired element.

Lemma 2.9. Let $M_{1}, M_{2}$ be two coprime positive integers, and let $\varphi: \mathrm{SL}_{2}(\mathbb{Z}) \rightarrow$ $\mathrm{SL}_{2}\left(\mathbb{Z} / M_{1} \mathbb{Z}\right)$ be the natural projection. Then $\varphi\left(\Gamma_{0}\left(M_{2}\right)\right)=\mathrm{SL}_{2}\left(\mathbb{Z} / M_{1} \mathbb{Z}\right)$.

Proof. By Chinese remainder theorem, we have

$$
\mathrm{SL}_{2}\left(\mathbb{Z} /\left(M_{1} M_{2} \mathbb{Z}\right)\right) \simeq \mathrm{SL}_{2}\left(\mathbb{Z} / M_{1} \mathbb{Z}\right) \times \mathrm{SL}_{2}\left(\mathbb{Z} / M_{2} \mathbb{Z}\right)
$$

Given any $g \in \mathrm{SL}_{2}\left(\mathbb{Z} / M_{1} \mathbb{Z}\right)$, let $g^{\prime} \in \mathrm{SL}_{2}\left(\mathbb{Z} /\left(M_{1} M_{2} \mathbb{Z}\right)\right)$ correspond to $(g, 1) \in$ $\mathrm{SL}_{2}\left(\mathbb{Z} / M_{1} \mathbb{Z}\right) \times \mathrm{SL}_{2}\left(\mathbb{Z} / M_{2} \mathbb{Z}\right)$ via the above isomorphism. It's well-known that for any integer $M, \mathrm{SL}_{2}(\mathbb{Z}) \longrightarrow \mathrm{SL}_{2}(\mathbb{Z} / M \mathbb{Z})$ is surjective. So we choose a matrix $G$ such that $G \equiv g^{\prime}\left(\bmod M_{1} M_{2}\right)$. Then $G \in \Gamma\left(M_{2}\right) \subset \Gamma_{0}\left(M_{2}\right)$ and $\varphi(G)=g$.

Example 2.1. Now we construct an admissible embedding $K \hookrightarrow M_{2}(\mathbb{Q})$ as following. Since $\ell \mid N_{0}$ implies that $\ell$ is split in $K$, there exists an integral ideal $\mathfrak{N}_{0}$ of $\mathcal{O}_{K}$ such that $\mathcal{O}_{K} / \mathfrak{N}_{0} \simeq \mathbb{Z} / N_{0}$, which implies $\mathbb{Z}+\mathfrak{N}_{0}=\mathcal{O}_{K}$. Then there exists $n \in \mathbb{Z}$ and $m \in \mathfrak{N}_{0}$ such that

$$
\frac{D+\sqrt{D}}{2}=n+m .
$$

Taking trace and norm, we get

$$
D=2 n+(m+\bar{m}) \quad \text { and } \quad \frac{D^{2}-D}{4}=n^{2}+n(m+\bar{m})+m \bar{m}
$$

Since $m \bar{m} \in \mathfrak{N}_{0} \overline{\mathfrak{N}_{0}}=N_{0} \mathcal{O}_{K}$ and it is an integer, we have $m \bar{m}=N_{0} b$ for some $b \in \mathbb{Z}$. Let $a=D-2 n$. We see that

$$
D=a^{2}-4 N_{0} b .
$$

It's easy to check that $\left(a, b, N_{0}\right)=1$. Given an integer $c$ such that $(c, N)=1$, we let the embedding $i_{c}: K \longrightarrow B$ be given by

$$
\frac{D+\sqrt{D}}{2} \longmapsto\left(\begin{array}{cc}
\frac{D+a}{2} & -c^{-1} \\
N_{0} b c & \frac{D-a}{2}
\end{array}\right), \text { or } \frac{D c+\sqrt{D c^{2}}}{2} \longmapsto\left(\begin{array}{cc}
\frac{D c+a c}{2} & -1 \\
N_{0} b c^{2} & \frac{D c-a c}{2}
\end{array}\right) .
$$

We can see this embedding is normalized in the sense of [18, p. 104], and

$$
h_{0}=\frac{a+\sqrt{D}}{2 N_{0} b c}
$$

We should mention that, for the normalized embedding, we have Shimura's reciprocity law, which interpretes the Galois action on Heegner points.

The modular curve $X_{K}(N)$ depends on the admissible embedding $K \hookrightarrow M_{2}(\mathbb{Q})$. However, we will prove that all those modular curves given by admissible embeddings are isomorphic over $\mathbb{Q}$. Let $i: K \hookrightarrow M_{2}(\mathbb{Q})$ be an admissible embedding. Let $H=i\left(\mathcal{O}_{K} / N_{1} \mathcal{O}_{K}\right) \subset \mathrm{GL}_{2}\left(\mathbb{Z} / N_{1} \mathbb{Z}\right)$, and let $H_{0}$ be the upper-triangular matrices in $\mathrm{GL}_{2}\left(\mathbb{Z} / N_{0} \mathbb{Z}\right)$; then $H=\prod_{p \mid N_{1}} H_{p}$, where $H_{p} \subset \mathrm{GL}_{2}\left(\mathbb{Z} / p^{\operatorname{ord}_{p} N_{1}} \mathbb{Z}\right)$. Then

$$
X_{K}(N)=X\left(N_{0} N_{1}\right) /\left(H \times H_{0}\right)
$$

If $i^{\prime}$ is another admissible embedding, and for any $p \mid N_{1}, H_{p}$ and $H_{p}^{\prime}$ are conjugate in $\mathrm{GL}_{2}\left(\mathbb{Z} / p^{\operatorname{ord}_{p} N_{1}} \mathbb{Z}\right)$, we obviously have

$$
X\left(N_{0} N_{1}\right) /\left(H \times H_{0}\right) \simeq X\left(N_{0} N_{1}\right) /\left(H^{\prime} \times H_{0}\right)
$$

In fact, $H_{p}$ is the image of the composition homomorphism of $\mathbb{Z}_{p^{2}}^{\times} \rightarrow \mathrm{GL}_{2}\left(\mathbb{Z}_{p}\right)$ and $\mathrm{GL}_{2}\left(\mathbb{Z}_{p}\right) \rightarrow \mathrm{GL}_{2}\left(\mathbb{Z}_{p} / p^{\operatorname{ord}_{p}\left(N_{1}\right)} \mathbb{Z}_{p}\right)$. Lemma 2.7 implies that $H_{p}$ and $H_{p}^{\prime}$ are conjugate in $\mathrm{GL}_{2}\left(\mathbb{Z} / p^{\operatorname{ord}_{p} N_{1}} \mathbb{Z}\right)$. Thus,

Proposition 2.10. The modular curve $X_{K}(N)$ is unique up to an isomorphism over $\mathbb{Q}$.

Cusps. Now we study the cusps on $X_{K}(N)$.
Lemma 2.11. Let $\zeta_{N_{1}}$ be a primitive $N_{1}$-th root of unity. Then the cusp $[\infty]$ of $X_{K}(N)$ is defined over $\mathbb{Q}\left(\zeta_{N_{1}}\right)$.

Proof. In the adelic language, we have the following complex uniformization:

$$
X_{K}(N)(\mathbb{C})=\mathrm{GL}_{2}^{+}(\mathbb{Q}) \backslash \mathcal{H} \times \mathrm{GL}_{2}(\widehat{\mathbb{Z}}) / \widehat{R}^{\times} \cup\{\text { cusps }\},
$$

where the cusps are

$$
\mathrm{GL}_{2}^{+}(\mathbb{Q}) \backslash \mathbb{P}^{1}(\mathbb{Q}) \times \mathrm{GL}_{2}(\widehat{\mathbb{Z}}) / \widehat{R}^{\times}
$$

The cusps are all defined over $\mathbb{Q}^{\text {ab }}$. By [16, p. 507], if we let $r: \widehat{\mathbb{Q}}^{\times} / \mathbb{Q}^{\times} \rightarrow$ $\operatorname{Gal}\left(\mathbb{Q}^{\text {ab }} / \mathbb{Q}\right)$ be the Artin map, then $r(x) \in \operatorname{Gal}\left(\mathbb{Q}^{\text {ab }} / \mathbb{Q}\right)$ acts on the cusps by left multiplication the matrix $\left(\begin{array}{ll}x & 0 \\ 0 & 1\end{array}\right)$. Since $\widehat{\mathbb{Q}}^{\times} / \mathbb{Q}^{\times} \simeq \widehat{\mathbb{Z}}^{\times}$, if $x \in \widehat{\mathbb{Z}}^{\times}$is such that $r(x) \cdot[\infty, 1]=[\infty, 1]$, there exists $\left(\begin{array}{cc}\alpha & \beta \\ 0 & \gamma\end{array}\right) \in \mathrm{GL}_{2}^{+}(\mathbb{Q})$, such that $\left(\begin{array}{cc}\alpha & \beta \\ 0 & \gamma\end{array}\right)\left(\begin{array}{cc}x & 0 \\ 0 & 1\end{array}\right) \in$ $\widehat{R}^{\times}$, which implies
$\gamma \in \mathbb{Z}_{p}^{\times}, \alpha x_{p} \in \mathbb{Z}_{p}^{\times}, \beta \in N_{1} \mathbb{Z}_{p}$ for all $p$, and $\alpha x_{p} \equiv \gamma\left(\bmod N_{1}\right)$ for all $p \mid N_{1}$.
Hence $\alpha=\gamma= \pm 1$, and $x_{p} \equiv 1\left(\bmod N_{1}\right)$. So the definition field of $[\infty, 1]$ corresponds to

$$
\widehat{\mathbb{Q}}^{\times} / \mathbb{Q}^{\times} \mathbb{Z}^{\times\left(N_{1}\right)} \prod_{p \mid N_{1}}\left(1+N_{1} \mathbb{Z}_{p}\right)
$$

via class field theory, this is $\mathbb{Q}\left(\zeta_{N_{1}}\right)$.
In the following, we fix the embedding $i_{c}: K \hookrightarrow M_{2}(\mathbb{Q})$ given in Example 2.1.
Atkin-Lehner operator. For each $p \mid N_{0}$, let

$$
w_{p}=\left(\begin{array}{cc}
0 & 1 \\
p^{\operatorname{ord}_{p} N} & 0
\end{array}\right) \in \mathrm{GL}_{2}\left(\mathbb{Q}_{p}\right)
$$

be the local Atkin-Lehner operator.
Although it will not be used later in this paper, to compare with equation (5.1) of [7], we give a description of $w_{p} P$ for $p \mid N_{0}$ and $P=\left(\mathbb{C} / \mathfrak{a}, \mathcal{N}^{-1} \mathfrak{a} / \mathfrak{a}, H\binom{\frac{v}{N_{1}}}{\frac{u}{N_{1}}}\right)$.

Write $N_{0}=p^{k} m$ with $(p, m)=1$. We can choose $a, b \in \mathbb{Z}$ such that $p^{k} a+m b=1$.
Let $g=\left(\begin{array}{cc}p^{k} & 1 \\ -N_{0} b & p^{k} a\end{array}\right) \in \mathrm{GL}_{2}^{+}(\mathbb{Q}) \cap M_{2}(\mathbb{Z})$, such that $g^{-1} w_{p} \in \widehat{R}^{\times}$, so

$$
w_{p} P=\left[v / u, w_{p}\right]=\left[g^{-1} v / u, 1\right]=\left(\mathbb{C} / \mathbb{Z} \cdot g^{-1} v / u+\mathbb{Z},\left\langle\frac{1}{N_{0}}\right\rangle, H\binom{\frac{g^{-1} v / u}{N_{1}}}{\frac{1}{N_{1}}}\right)
$$

Modifying it, we get

$$
w_{p} P=\left(\mathbb{C} / \mathfrak{a}^{\prime}, \mathcal{N}^{\prime-1} \mathfrak{a}^{\prime} / \mathfrak{a}^{\prime}, H\binom{\frac{a v-u / p^{k}}{N_{1}}}{\frac{m b v+u}{N_{1}}}\right)
$$

where $\mathfrak{a}^{\prime}=\mathbb{Z}\left\langle v, u / p^{k}\right\rangle$ and $\mathcal{N}^{\prime-1} \mathfrak{a}^{\prime}=\mathbb{Z}\left\langle v / p^{k}, u /\left(p^{k} m\right)\right\rangle$. Considering the quotient $\operatorname{map} \xi: X_{K}(N) \rightarrow X_{0}\left(N_{0}\right)$ induced by $\Gamma_{K}(N) \subset \Gamma_{0}\left(N_{0}\right)$, which is defined over $\mathbb{Q}$, the above argument says that $\xi \circ w_{p}=w_{p} \circ \xi$, where the action of $w_{p}$ on $X_{0}\left(N_{0}\right)$ is defined by [7, p. 90].

Take $j=\left(\begin{array}{cc}1 & 0 \\ a c & -1\end{array}\right)$, then $k j=j \bar{k}$ for all $k \in K$ where $^{-}$is the complex conjugation of $K$ and coincides with the nontrivial element in $\operatorname{Gal}(K / \mathbb{Q})$.

Define

$$
w=j^{\left(N_{0}\right)} \cdot \prod_{p \mid N_{0}} w_{p} \in \mathrm{GL}_{2}(\widehat{\mathbb{Q}}) \cap M_{2}(\widehat{\mathbb{Z}})
$$

Since $w$ normalizes $\widehat{R}^{\times}$, it acts on $X_{K}(N)$. To study the action of $w$ on $X_{K}(N)$, we can prove the following lemma:

Lemma 2.12. There exists $t_{0} \in \widehat{K}^{\times}$and $u \in \widehat{R}^{\times}$such that $w=t_{0} j u$.
Proof. For $p \mid N_{0}$, let $k=\operatorname{ord}_{p} N_{0} \geq 1, K_{p}^{\times}=\left(\mathbb{Q}_{p}+\mathbb{Q}_{p}(\sqrt{D})\right)^{\times}$. Let $x, y \in \mathbb{Q}_{p}$; then

$$
(x+y \sqrt{D}) j_{p}^{-1} w_{p}=\left(\begin{array}{cc}
-2 p^{k} y & x+a y \\
-p^{k}(x+a y) & a(x+a y)-2 N_{0} b y
\end{array}\right)
$$

So we choose $\operatorname{ord}_{p} y=-k-\operatorname{ord}_{p} 2, x+a y \in \mathbb{Z}_{p}$ and such that $a(x+a y) \in \mathbb{Z}_{p}^{\times}$. Then let $t_{0, p}=x+y \sqrt{D}$.

For $p \nmid N_{0}$, let $t_{0, p}=1$. Then such choice of $t_{0}$ works.

Remark 2.13. By Shimura reciprocity law, if we use $[x] \mapsto \overline{[x]}$ to denote the complex conjugation on $X_{K}(N)(\mathbb{C})$, then

$$
\overline{\left[h_{0}, g\right]}=\left[h_{0}, j g\right] \forall g \in \mathrm{GL}_{2}\left(\mathbb{A}_{f}\right)
$$

Lemma 2.12 in fact tells us that the action of $w$ on certain Heegner points is a combination of a Galois action and complex conjugation. For details, we can see the proof of Lemma 3.11

Hecke correspondences. Let $\ell \nmid N$ be a prime. The Hecke correspondence $T_{\ell}$ on $X_{U}$ is defined by

$$
T_{\ell}\left(E, C, H\binom{x_{1}}{x_{2}}\right)=\sum_{i}\left(E / C_{i},\left(C+C_{i}\right) / C_{i}, H\binom{x_{1} \bmod C_{i}}{x_{2} \bmod C_{i}}\right)
$$

where the sum is taken over all cyclic subgroups $C_{i}$ of $E$ of order $\ell, \alpha_{i}$ is given by $\left(\mathbb{Z} / N_{1} \mathbb{Z}\right)^{2} \xrightarrow{\alpha} E\left[N_{1}\right] \simeq\left(E / C_{i}\right)\left[N_{1}\right] . \quad E\left[N_{1}\right] \simeq\left(E / C_{i}\right)\left[N_{1}\right]$ is because $(\ell, N)=1$. This is just by definition.
2.2. Gross-Zagier formula. Let $E$ be an elliptic curve of conductor $N$, let $K$ be an imaginary quadratic field of discriminant $D$ and let $\chi$ be a ring class character over $K$ of conductor $c$. Assume

$$
E, K, \chi \text { satisfy the condition (*). }
$$

Then we can write $N=N_{0} N_{1}^{2}$, where $p \mid N$ is inert in $K$ if and only if $p \mid N_{1}$.
Embed $K$ in $M_{2}(\mathbb{Q})$ by $i_{c}$. There is a modular parametrization $f: X_{K}(N) \rightarrow E$ mapping $[\infty]$ to the identity of $E$. If $f_{1}, f_{2}$ are two such morphisms, then there exist integers $n_{1}, n_{2}$ such that $n_{1} f_{1}=n_{2} f_{2}$. Let $h_{0}$ be the point in $\mathcal{H}$ fixed by $K^{\times}$; then $\mathcal{O}_{c}=\mathbb{Z}+\mathbb{Z} h_{0}^{-1}, \mathcal{N}=\mathbb{Z}+\mathbb{Z} N_{0}^{-1} h_{0}^{-1}$ is an invertible ideal of $\mathcal{O}_{c}$ such that $\mathcal{N} / \mathcal{O}_{c} \cong \mathbb{Z} / N_{0} \mathbb{Z}$. Consider the following Heegner point on $X_{K}(N)$ of conductor $c$ :

$$
P=\left(\mathbb{C} / \mathcal{O}_{c}, \mathcal{N} / \mathcal{O}_{c}, H\binom{\frac{1}{N_{1}}}{\frac{h_{0}}{N_{1}}}\right) \in X_{K}(N)\left(H_{c}\right) .
$$

Form the cycle:

$$
P_{\chi}(f)=\sum_{\sigma \in \operatorname{Gal}\left(H_{c} / K\right)} f\left(P^{\sigma}\right) \chi(\sigma) \in E\left(H_{c}\right) \otimes_{\mathbb{Z}} \mathbb{C}
$$

Theorem 2.14 (Explicit Gross-Zagier formula [3). We have the following equation:

$$
\begin{equation*}
L^{\prime}(1, E, \chi)=2^{-\mu(N, D)} \cdot \frac{8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(N)}}{u^{2} c \sqrt{|D|}} \frac{\widehat{h}_{K}\left(P_{\chi}(f)\right)}{\operatorname{deg} f} \tag{GZ}
\end{equation*}
$$

Here $\phi$ is the normalized newform associated to $E, \mu(N, D)$ is the number of prime factors of $(N, D), u=\left[\mathcal{O}_{K}^{\times}: \mathbb{Z}^{\times}\right], \widehat{h}_{K}$ is the Néron-Tate height pairing over $K$ and $(\phi, \phi)_{\Gamma_{0}(N)}$ is the Petersson inner product defined by

$$
(\phi, \phi)_{\Gamma_{0}(N)}=\int_{\Gamma_{0}(N) \backslash \mathcal{H}}|\phi(x+i y)|^{2} d x d y
$$

2.3. Euler system. Let $S$ be a finite set of primes containing the prime factors of $6 c N D_{K}$,

$$
\mathbb{N}_{S}=\{n \text { is an integer : } \ell \mid n \Rightarrow \ell \notin S\} .
$$

For any $\ell, m \in \mathbb{N}_{S}$ with $\ell$ a prime and $\ell \nmid m$, let $P_{m}=\left(\mathbb{C} / \mathfrak{a}_{m}, \mathcal{N}_{m}^{-1} \mathfrak{a}_{m} / \mathfrak{a}_{m}, \alpha_{m}\right)$ be a Heegner point of conductor cm . Let $P_{m \ell}=\left(\mathbb{C} / \mathfrak{a}_{m \ell}, \mathcal{N}_{m \ell}^{-1} \mathfrak{a}_{m \ell} / \mathfrak{a}_{m \ell}, \alpha_{m \ell}\right)$, such that $\mathcal{N}_{m \ell}=\mathcal{N}_{m} \cap \mathcal{O}_{m \ell}, \mathfrak{a}_{m \ell}=\mathfrak{a} \cap \mathcal{O}_{m \ell}$, and $\alpha_{m \ell}$ is the composition

$$
\left(\mathbb{Z} / N_{1} \mathbb{Z}\right)^{2} \xrightarrow{\alpha_{m}} N_{1}^{-1} \mathfrak{a}_{m} / \mathfrak{a}_{m} \xrightarrow{\sim} N_{1}^{-1} \mathfrak{a}_{m \ell} / \mathfrak{a}_{m \ell} .
$$

Theorem 2.15. We have that $\left[H_{m \ell}: H_{m}\right]=(\ell+1) / u_{m}$ if $\ell$ is inert in $K$ and $(\ell-1) / u_{m}$ if $\ell$ is split and

$$
u_{m} \sum_{\sigma \in \operatorname{Gal}\left(H_{m \ell} / H_{m}\right)} P_{m \ell}^{\sigma}= \begin{cases}\mathrm{T}_{\ell} P_{m}, & \text { if } \ell \text { is inert in } K, \\ \left(\mathrm{~T}_{\ell}-\sum_{w \mid \ell} \operatorname{Frob}_{w}\right) P_{m}, & \text { if } \ell \text { is split in } K,\end{cases}
$$

where $\mathrm{T}_{\ell}$ is the Hecke correspondence, $\operatorname{Frob}_{w}$ is the Frobenius at $w \mid \ell$ in $\operatorname{Gal}\left(H_{m} / K\right)$, and $u_{m}=1$ if $m \neq 1$ and $u_{1}=\left[\mathcal{O}_{K}^{\times}: \mathbb{Z}^{\times}\right]$.

This theorem is proved in general by [10, Proposition 4.8] or [20, Theorem 3.1.1].
2.4. Waldspurger formula and Gross points. Let $\phi=\sum_{n=1}^{\infty} a_{n} q^{n}$ be a newform of weight 2 , level $\Gamma_{0}(N)$, normalized such that $a_{1}=1$. Let $K$ be an imaginary quadratic field of discriminant $D$ and $\chi$ a ring class character over $K$ of conductor $c$. Let $L(s, \phi, \chi)$ be the Rankin-Selberg convolution of $\phi$ and $\chi$.

Assume that $(c, N)=1$. Denote by $\mathbb{S}$ the set of primes $p \mid N$ satisfying one of the following conditions:

- $p$ is inert in $K$ with $\operatorname{ord}_{p}(N)$ odd;
- $p \mid D \operatorname{ord}_{p}(N)=1$ and $\chi([\mathfrak{p}])=a_{p}$ where $\mathfrak{p}$ is the prime of $\mathcal{O}_{K}$ above $p$ and $[\mathfrak{p}]$ is its class in $\operatorname{Pic}\left(\mathcal{O}_{c}\right)$;
- $p \mid D, \operatorname{ord}_{p}(N) \geq 2$ and the local root number of $L(s, \phi, \chi)$ at $p$ equals $-\eta_{p}(-1)$ where $\eta_{p}$ is the quadratic character for $K_{p} / \mathbb{Q}_{p}$.
Assume $\mathbb{S}$ has odd cardinality; then the sign of $L(s, \phi, \chi)$ is +1 . Let $B$ be the definite quaternion algebra defined over $\mathbb{Q}$ ramified exactly at primes in $\mathbb{S} \cup\{\infty\}$. Fix an embedding from $K$ into $B$. Let $R$ be an order in $B$ with discriminant $N$ and such that $R \cap K=\mathcal{O}_{c}$. Denote by $\hat{R}=R \otimes_{\mathbb{Z}} \hat{\mathbb{Z}}$ and $U=\hat{R}^{\times}$which is an open compact subgroup of $\hat{B}^{\times}$. Consider the Shimura set $X_{U}=B^{\times} \backslash \hat{B}^{\times} / U$ which is a finite set. A point in $X_{U}$ represented by $x \in \hat{B}^{\times}$is denoted by $[x]$. Note that for $p \mid(D, N), K_{p}^{\times}$normalizes $U$ and then $K_{p}^{\times}$acts on $X_{U}$ by right multiplication. Let

$$
\mathbb{C}\left[X_{U}\right]^{0}=\left\{f \in \mathbb{C}\left[X_{U}\right] \mid \sum_{x \in X_{U}} f(x)=0\right\} .
$$

For each $p \nmid N$, there are Hecke correspondences $T_{p}$ and $S_{p}$. In this case, $B_{p}$ is split while $U_{p}$ is maximal. Then the quotient $B_{p}^{\times} / U_{p}$ can be identified with $\mathbb{Z}_{p}$-lattices in $\mathbb{Q}_{p}^{2}$. Then for any $[x] \in X_{U}$,

$$
S_{p}[x]:=\left[x^{(p)} s_{p}\right], \quad T_{p}[x]:=\sum_{h_{p}}\left[x^{(p)} h_{p}\right],
$$

where if $x_{p}$ corresponds to a lattice $\Lambda$, then $s_{p}$ is the lattice $p \Lambda$ and the set $\left\{h_{p}\right\}$ is the set of sublattices $\Lambda^{\prime}$ of $\Lambda$ with $\left[\Lambda: \Lambda^{\prime}\right]=p$. There is then a line $V(\phi, \chi)$ of $\mathbb{C}\left[X_{U}\right]^{0}$ characterized as follows:

- for any $p \nmid N, T_{p}$ acts on $V(\phi, \chi)$ by $a_{p}$ and $S_{p}$ acts trivially;
- for any $p \mid(D, N)$ with $\operatorname{ord}_{p}(N) \geq 2, K_{p}^{\times}$acts on $V(\phi, \chi)$ by $\chi_{p}$.

Let $f$ be a nonzero vector in $V(\phi, \chi)$ and consider the period

$$
P_{\chi}(f)=\sum_{\sigma \in \operatorname{Gal}\left(H_{c} / K\right)} f(\sigma) \chi(\sigma)
$$

where the embedding of $K$ into $B$ induces a map

$$
\operatorname{Gal}\left(H_{c} / K\right)=K^{\times} \backslash \hat{K}^{\times} / \widehat{\mathcal{O}}_{c}^{\times} \longrightarrow X_{U}
$$

Theorem 2.16 (Explicit Waldspurger formula [3). We have the following equation:

$$
L(1, \phi, \chi)=2^{-\mu(N, D)} \cdot \frac{8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(N)}}{u^{2} c \sqrt{|D|}} \frac{\left|P_{\chi}(f)\right|^{2}}{\langle f, f\rangle}
$$

where the pairing is given by

$$
\langle f, f\rangle=\sum_{[x] \in X_{U}}|f(x)|^{2} w([x])^{-1}
$$

and $w([x])$ is the order of the finite group $\left(B^{\times} \cap x U x^{-1}\right) /\{ \pm 1\}$.
There is an analogue to Heegner points, the so-called Gross points. Let $S$ and $\mathbb{N}_{S}$ be the same as in Section 2.3 ,
Definition 2.17. Let $m \in \mathbb{N}_{S}$. A point $x_{m} \in K^{\times} \backslash \hat{B}^{\times} / U$ is called a Gross point of conductor $c m$, if $x_{m} U x_{m}^{-1} \cap \hat{K}^{\times}=\widehat{\mathcal{O}}_{c m}^{\times}$.

Each element in $K^{\times} \backslash \widehat{K}^{\times} / \widehat{\mathcal{O}}_{c m}^{\times}$acts on $x_{m}$ by left multiplication. This induces an action of $\operatorname{Gal}\left(H_{c m} / K\right)$ on $x_{m}$, also called the Galois action.

For each prime $\ell \in \mathbb{N}_{S}$, fix an isomorphism $\beta_{\ell}: B_{\ell} \xrightarrow{\sim} M_{2}\left(\mathbb{Q}_{\ell}\right)$, such that $\beta_{\ell}\left(U_{\ell}\right)=\mathrm{GL}_{2}\left(\mathbb{Z}_{\ell}\right)$, and, under this isomorphism, we have

- $\beta_{\ell}\left(K_{\ell}\right)=\left\{\left(\begin{array}{ll}a & 0 \\ 0 & b\end{array}\right): a, b \in \mathbb{Q}_{\ell}\right\}$, if $\ell$ is split in $K$;
- $\beta_{\ell}\left(K_{\ell}\right)=\left\{\left(\begin{array}{cc}a & b \delta \\ b & a\end{array}\right): a, b \in \mathbb{Q}_{\ell}\right\}$, where $\delta \in \mathbb{Z}_{p}^{\times} \backslash \mathbb{Z}_{p}^{\times 2}$, if $\ell$ is inert in $K$.

For $m \in \mathbb{N}_{S}$, define $x_{m} \in \widehat{B}^{\times}$by

$$
\left(x_{m}\right)_{\ell}= \begin{cases}\beta_{\ell}^{-1}\left(\begin{array}{cc}
\ell^{\text {ord }_{\ell} m} & 0 \\
0 & 1
\end{array}\right) & \ell \mid m \\
1 & \\
& \ell \nmid m\end{cases}
$$

Then the image of $x_{m}$ in $K^{\times} \backslash \widehat{B}^{\times} / U$, still denoted by $x_{m}$, is a Gross point of conductor cm .

Theorem 2.18. For any $\ell, m \in \mathbb{N}_{S}$ with $\ell$ a prime and $\ell \nmid m$, we have that

$$
u_{m} \sum_{\sigma \in \operatorname{Gal}\left(H_{c m \ell} / H_{c m}\right)}\left[\sigma \cdot x_{m \ell}\right]= \begin{cases}T_{\ell}\left[x_{m}\right], & \text { if } \ell \text { is inert in } K, \\ \left(T_{\ell}-\sum_{w \mid \ell} \operatorname{Frob}_{w}\right)\left[x_{m}\right], & \text { if } \ell \text { is split in } K,\end{cases}
$$

where the equality holds as divisors on $X_{U}$, with $\mathrm{Frob}_{w}$ and $u_{m}$ the same as Theorem 2.15

The proof is the same as the norm relation of Heegner points on Shimura curves. One can refer to [10, Proposition 4.8] or [20, Theorem 3.1.1].

## 3. Quadratic twists of $X_{0}(36)$

The modular curve $X_{0}(36)$ has genus one and its cusp $[\infty]$ is rational over $\mathbb{Q}$ so that $E=\left(X_{0}(36),[\infty]\right)$ is an elliptic curve defined over $\mathbb{Q}$. The elliptic curve $E$ has CM by $\mathbb{Q}(\sqrt{-3})$ and has minimal Weierstrass equation

$$
y^{2}=x^{3}+1 .
$$

Note that its Tamagawa numbers are $c_{2}=3, c_{3}=2$ and $E(\mathbb{Q}) \cong \mathbb{Z} / 6 \mathbb{Z}$ is generated by the cusp $[0]=(2,3)$. We use $T$ to denote the nontrivial 2 -torsion point in the following. Denote by $L^{\text {alg }}(E, s)$ the algebraic part of $L(E, s)$. Then $L^{\text {alg }}(E, 1)=$ $1 / 6$.

For a nonzero integer $m$, let $E^{(m)}: y^{2}=x^{3}+m^{3}$ be the quadratic twist of $E$ by the field $\mathbb{Q}(\sqrt{m})$. Then $E^{(m)}$ and $E^{(-3 m)}$ are 3-isogenous to each other.

Lemma 3.1. Let $D \in \mathbb{Z}$ be a fundamental discriminant of a quadratic field. Then the sign for the functional equation of $E^{(D)}$, denoted by $\epsilon\left(E^{(D)}\right)$, is

$$
(-1)^{\#\{p \mid D, p=2,3, \infty\}}
$$

where $\infty \mid D$ means that $D<0$.
Proof. For each $D$, denote by $K=\mathbb{Q}(\sqrt{D})$; then

$$
L\left(s, E_{K}\right)=L(s, E) L\left(s, E^{(D)}\right),
$$

where $L\left(s, E_{K}\right)$ is the base change $L$-function and it suffices to determine the sign of $L\left(s, E_{K}\right)$. Note that the local components of the cuspidal automorphic representation for $E$ at places 2 and 3 are supercuspidal with conductor 2; then by [19, Proposition 3.5], the local root number for the base change $L$-function at places 2 (resp. 3) is negative if and only if $2 \mid D$ (resp. $3 \mid D$ ). Meanwhile, the local root number at $\infty$ is positive if and only if $D$ is positive and for any place not dividing $6 \infty$ it is positive. Summing up, the result holds.
3.1. The Waldspurger formula. Let $B$ be the definite quaternion algebra over $\mathbb{Q}$ ramified at $3, \infty$; then we know that

$$
B=\mathbb{Q}+\mathbb{Q} i+\mathbb{Q} j+\mathbb{Q} k, \quad i^{2}=-1, j^{2}=-3, k=i j=-j i
$$

Let $\mathcal{O}_{B}=\mathbb{Z}[1, i,(i+j) / 2,(1+k) / 2]$ be a maximal order of $B$. The unit group $\mathcal{O}_{B}^{\times}$ of $\mathcal{O}_{B}$ is equal to

$$
\{ \pm 1, \pm i, \pm(i+j) / 2, \pm(i-j) / 2, \pm(1+k) / 2, \pm(1-k) / 2\}
$$

Let $K=\mathbb{Q}(\sqrt{-3})$ and $\eta: \widehat{\mathbb{Q}}^{\times} / \mathbb{Q}^{\times} \rightarrow\{ \pm 1\}$ be the quadratic character associated to $K$. Embed $K \hookrightarrow B$ by sending $\sqrt{-3}$ to $k$, this induces an embedding $\widehat{K}^{\times} \hookrightarrow \widehat{B}^{\times}$.

Let $\pi=\otimes_{v} \pi_{v}$ be the automorphic representation of $B_{\mathbb{A}}^{\times}$corresponding to $E$ via the modularity of $E$ and the Jacquet-Langlands correspondence. Let $\mathcal{R}=\prod_{p} \mathcal{R}_{p}$ be an order of $\widehat{B}^{\times}$defined as follows. If $p=2$, then $\mathcal{R}_{2}=\mathcal{O}_{K, 2}+2 \mathcal{O}_{B, 2}$. If $p=3$, then $\mathcal{R}_{3}=\mathcal{O}_{K, 3}+\lambda \mathcal{O}_{B, 3}$ where $\lambda \in B^{\times}$is a uniformizer of $B_{3}$; for example, we may choose $\lambda=k$, which is also a uniformizer of $K_{3}$. For $p \nless 6, \mathcal{R}_{p}=\mathcal{O}_{B, p}$. Denote by $U=\mathcal{R}^{\times}$. Then $U$ is an open compact subgroup of $\widehat{B}^{\times}$.

The local components of $\pi$ have the following properties:

- $\pi_{\infty}$ is trivial;
- $\pi_{p}$ is unramified if $p \neq 2,3, \infty$, i.e., $\pi^{\mathcal{O}_{B, p}}$ is one dimensional;
- $\pi_{2}^{\mathcal{O}_{K, 2}^{\times}}$is one dimensional and $\pi_{3}^{\mathcal{O}_{K, 3}^{\times}}$is two dimensional.

The first two properties are standard, while the last property comes from (3) proposition 3.8]. Then $\pi^{U}$ is a representation of $B_{3}^{\times}$with dimension 2. As $K_{3}^{\times}$-modules, $\pi^{U}=\mathbb{C} \chi_{+} \oplus \mathbb{C} \chi_{-}$where $\chi_{+}$is the trivial character of $K_{3}^{\times}$and $\chi_{-}$is the nontrivial quadratic unramified character on $K_{3}^{\times}$.

This representation $\pi^{U}$ is naturally realized as a subspace of the space of the infinitely differentiable complex-valued functions $C^{\infty}\left(B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times}\right)$. The space $\pi^{U}$ is contained in the space $C^{\infty}\left(B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U\right)$ and is perpendicular to the spectrum consisting of characters (the residue spectrum). In fact, we have the following more
detailed proposition, which are easy calculations on automorphic representations, based on the discussion above:
Proposition 3.2. (1) $\pi^{U}$ has an orthonormal basis $f_{+}$, $f_{-}$under the Petersson inner product defined by

$$
\|f\|^{2}=\int_{B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times}}|f(g)|^{2} d g
$$

with the Tamagawa measure $\operatorname{Vol}\left(B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times}\right)=2$.
(2) Moreover, $f_{+}\left(\right.$resp. $\left.f_{-}\right)$is the function on $B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U$, supported on those $g \in \widehat{B}^{\times}$with $\chi_{0}(g)=+1$ (resp. $=-1$ ), valued in $0, \pm 1$ with total mass zero, where $\chi_{0}$ is the composition of the following morphisms:

$$
B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U \xrightarrow{\text { det }} \widehat{\mathbb{Q}}^{\times} \xrightarrow{\eta} \pm 1 .
$$

(3) For any $t \in K_{3}^{\times}, \pi(t) f_{+}=\chi_{+}(t) f_{+}$and $\pi(t) f_{-}=\chi_{-}(t) f_{-}$.

The values of $f_{ \pm}$on Gross points essentially induce Theorem 1.3, via explicit Waldspurger formula, as we will see later.

Since the class number of $B$ with respect to $\mathcal{O}_{B}$ is 1 by [24, p. 152], one has

$$
\widehat{B}^{\times}=B^{\times} \widehat{\mathcal{O}}_{B}^{\times}=B^{\times} B_{3}^{\times} \widehat{\mathcal{O}}_{B}^{\times(3)} .
$$

Therefore,

$$
B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U=B^{\times} \backslash B^{\times} B_{3}^{\times} \widehat{\mathcal{O}}_{B}^{\times(3)} / U_{2} U_{3} \widehat{\mathcal{O}}_{B}^{\times(6)}=H \backslash B_{3}^{\times} \mathcal{O}_{B, 2}^{\times} / U_{2} U_{3},
$$

where $H=B^{\times} \cap B_{3}^{\times} \widehat{\mathcal{O}}_{B}^{\times(3)}=\mathcal{O}_{B}^{\times} \lambda^{\mathbb{Z}} \subset B_{3}^{\times} \mathcal{O}_{B, 2}^{\times}$and the last inclusion is given by the diagonal embedding.

Lemma 3.3. The double coset $H \backslash \mathcal{O}_{B, 2}^{\times} / U_{2}$ is trivial and $H \cap U_{2} \backslash B_{3}^{\times} / U_{3}=\mathcal{O}_{B, 3}^{\times} / U_{3}$.
Proof. The proof is elementary. First, we prove that $H \backslash \mathcal{O}_{B, 2}^{\times} / U_{2}$ is trivial. Recall that $U_{2}=\mathcal{O}_{K, 2}^{\times}\left(1+2 M_{2}\left(\mathbb{Z}_{2}\right)\right)$. As $\mathrm{GL}_{2}\left(\mathbb{Z}_{2}\right) /\left(1+2 M_{2}\left(\mathbb{Z}_{2}\right)\right)=\mathrm{GL}_{2}\left(\mathbb{F}_{2}\right)$, for any $g \in \mathrm{GL}_{2}\left(\mathbb{F}_{2}\right)$, one may find $h \in H$ and $u \in \mathcal{O}_{K, 2}^{\times}$such that $g \equiv h u\left(\bmod 2 \mathbb{Z}_{2}\right)$. For the second claim, note that

$$
H \cap U_{2}=\left\langle k,-1, \frac{1+k}{2}\right\rangle .
$$

For any $x \in B_{3}^{\times}, x^{-1}(1+\lambda) x=1+x^{-1} \lambda x \in U_{3}$ where $\lambda$ is any uniformizer of $B_{3}^{\times}$. In particular, the action of $H \cap U_{2}$ on $B_{3}^{\times} / U_{3}$ is equal to the action of the group generated by some uniformizer. Hence $H \cap U_{2} \backslash B_{3}^{\times} / U_{3}=H \cap U_{2} \backslash\left(B_{3}^{\times} / U_{3}\right)=$ $\mathcal{O}_{B, 3}^{\times} / U_{3}$.

If we denote $\mathbb{Z}_{9}$ the integer ring for the unramified quadratic extension field of $\mathbb{Q}_{3}$, then

$$
\mathcal{O}_{B, 3}^{\times}=\mathbb{Z}_{9}^{\times}\left(1+\lambda \mathbb{Z}_{9}\right) ; U_{3}=\mathcal{O}_{K, 3}^{\times}\left(1+\lambda \mathcal{O}_{B, 3}\right)=\mu_{2}\left(1+3 \mathbb{Z}_{9}\right)\left(1+\lambda \mathbb{Z}_{9}\right),
$$

where $\mu_{2}=\{ \pm 1\}$. Hence

$$
\begin{aligned}
H \backslash B_{3}^{\times} \mathcal{O}_{B, 2}^{\times} / U_{2} U_{3} & \simeq H \cap U_{2} \backslash B_{3}^{\times} / U_{3} \\
& \simeq \mathcal{O}_{B, 3}^{\times} / U_{3} \\
& \simeq \mathbb{Z}_{9}^{\times} / \mu_{2}\left(1+3 \mathbb{Z}_{9}\right) \cong \mathbb{Z} / 4 \mathbb{Z}
\end{aligned}
$$

and we can identify $C^{\infty}\left(B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U\right)$ with $\mathbb{C}[\mathbb{Z} / 4 \mathbb{Z}]$.
The image of $B^{\times} \backslash \hat{B}^{\times} / U$ under the norm map is $\mathbb{Q}_{+}^{\times} \backslash \hat{\mathbb{Q}}^{\times} / \mathrm{Nr} U$. If $p \neq 3, \mathrm{Nr} U_{p}=$ $\mathbb{Z}_{p}^{\times}$while if $\mathrm{Nr}_{3}=1+3 \mathbb{Z}_{3}$. Therefore, by the approximation theorem,

$$
\mathbb{Q}_{+}^{\times} \backslash \hat{\mathbb{Q}}^{\times} / \mathrm{Nr} U=\mathbb{Z}_{3}^{\times} / \mathrm{Nr} U_{3}=\mathbb{Z}_{3}^{\times} / 1+3 \mathbb{Z}_{3} .
$$

In paticular, the cardinality of $\mathbb{Q}_{+}^{\times} \backslash \widehat{\mathbb{Q}}^{\times} / \mathrm{Nr} U$ is 2 . Forms in $C^{\infty}\left(B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U\right)$ of the form $\mu \circ \mathrm{Nr}$ for some Hecke character $\mu$ corresponds to characters on $\mathbb{C}[\mathbb{Z} / 4 \mathbb{Z}]$ of order dividing 2 . Summing up, we obtain
Lemma 3.4. There is a natural bijection

$$
\mathbb{Z}_{9}^{\times} / \mu_{2}\left(1+3 \mathbb{Z}_{9}\right) \xrightarrow{\sim} B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U
$$

which is induced by the embedding $\mathbb{Z}_{9}^{\times} \rightarrow B_{3}^{\times} \rightarrow \widehat{B}^{\times}$, and the left hand side of the above bijection is isomorphic to the cyclic group of order 4 . Via this bijection, the space $\pi^{U}$ is spanned by characters on the cyclic group with order not dividing 2 .

Since $\mathcal{O}_{K, 3}^{\times} \subset U_{3}, f$ is $\chi_{ \pm}$-eigen if and only if $\pi_{3}\left(\varpi_{3}\right) f= \pm f$, if and only if $f\left(\zeta^{a} \varpi_{3}\right)= \pm f\left(\zeta^{a}\right)$ for $a=0, \cdots, 3$ where $\zeta$ is a primitive 8-th root of unity in $\mathbb{Z}_{9}^{\times}$. Moreover, we may assume $\zeta \equiv 1+\sqrt{-1}\left(\bmod 1+3 \mathbb{Z}_{9}\right)$.

To compute $f\left(\zeta^{a} \varpi_{3}\right)$, since $k \in H \cap U_{2}$ and $f \in \pi^{U}$, we have

$$
f\left(\zeta^{a} \varpi_{3}\right)=f\left(k^{-1} \zeta^{a} \varpi_{3}\right)=f\left(k_{3}^{-1} \zeta^{a} \varpi_{3}\right),
$$

where $k_{3}$ denotes the 3 -component of $k$.
Take $\varpi_{3}=\sqrt{-3} \in K_{3}^{\times}$. Then

$$
f\left(k_{3}^{-1} \zeta^{a} \varpi_{3}\right)=f\left(k_{3}^{-1} \zeta^{a} k_{3}\right)=f\left(\zeta^{3 a}\right), \quad a \in \mathbb{Z} / 4 \mathbb{Z}
$$

because the conjugate action of $k_{3}$ on $\mathbb{Z}_{9}$ is the Galois conjugation. Thus

$$
\pi\left(\varpi_{3}\right) f(\zeta)=f\left(\zeta^{3}\right), \quad \pi\left(\varpi_{3}\right) f\left(\zeta^{a}\right)=f\left(\zeta^{a}\right) \quad \text { if } 2 a=0
$$

Thus, one may take $f_{+}$and $f_{-}$by

$$
\begin{array}{lll}
f_{+}(1)=1, & f_{+}\left(\zeta^{2}\right)=-1, & f_{+}(\zeta)=f_{+}\left(\zeta^{3}\right)=0 \text { and } \\
f_{-}(\zeta)=1, & f_{-}\left(\zeta^{3}\right)=-1, & f_{-}(1)=f_{-}\left(\zeta^{2}\right)=0
\end{array}
$$

Finally, we show that $\chi_{0}$ is the nontrivial element in the residue spectrum of $C^{\infty}\left(B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U\right)$ and $\chi_{0}\left(\zeta^{a}\right)=(-1)^{a}$ for $a=0, \cdots, 3$. Thus, up to $\pm 1, f_{+}$ (resp. $f_{-}$) is the function on $B^{\times} \backslash \widehat{B}^{\times} / \widehat{\mathbb{Q}}^{\times} U$, supported on those $g \in \widehat{B}^{\times}$with $\chi_{0}(g)=+1$ (resp. $=-1$ ), valued in $0, \pm 1$ with total mass zero. It is clear that $f_{+}$ and $f_{-}$is an orthonormal basis of $\pi^{U}$. We have completed the proof of Proposition 3.2.

Now let $M=q_{1} \ldots q_{r}$ with $q_{i} \equiv 5(\bmod 12)$. For any $q \mid M$, we take an isomorphism $\iota_{q}: B_{q} \xrightarrow{\sim} M_{2}\left(\mathbb{Q}_{q}\right)$ given by $i \mapsto\left(\begin{array}{cc}1 & 0 \\ 0 & -1\end{array}\right)$ and $k \mapsto\left(\begin{array}{ll}0 & 3 \\ 1 & 0\end{array}\right)$. In particular, $\iota_{q}\left(\mathcal{O}_{B, q}\right)=M_{2}\left(\mathbb{Z}_{q}\right)$. Denote by $x_{q} \in B_{q}^{\times}$an element such that $\iota_{q}\left(x_{q}\right)=$ $\left(\begin{array}{ll}q & \\ & 1\end{array}\right)$. Then $x_{q} \mathcal{O}_{B, q} x_{q}^{-1} \cap K_{q}=\mathcal{O}_{M, q}$. Take $x_{M}=\prod_{i} x_{q_{i}} \in \widehat{B}^{\times}$. Denote by

$$
f_{M}= \begin{cases}f_{+}\left(\cdot x_{M}\right) & \text { if } r \text { is even } \\ f_{-}\left(\cdot x_{M}\right) & \text { if } r \text { is odd }\end{cases}
$$

Let $\chi_{M}$ be the quadratic Hecke character of $K$ associated to $K(\sqrt{M}) / K$; then $\chi_{M}\left(\varpi_{3}\right)=(-1)^{r}$. Then $f_{M}$ is in the line $V\left(\pi, \chi_{M}\right)$ defined in Section 2.4 In particular, it satisfies that
(1) $\forall p \nmid 6 M, T_{p} f_{M}=a_{p} f_{M}$;
(2) $f_{M}$ is integer-valued with minimal norm;
(3) $\pi\left(\varpi_{3}\right) f_{M}=\chi_{M}\left(\varpi_{3}\right) f_{M}$.

Let $H_{M}$ be the ring class field of $K$ of conductor $M$, i.e., the abelian extension of $K$ with Galois group $\operatorname{Gal}\left(H_{M} / K\right) \simeq \operatorname{Pic}\left(\mathcal{O}_{M}\right)=\widehat{K}^{\times} / K^{\times} \widehat{\mathcal{O}}_{M}^{\times}$. The embedding $K \hookrightarrow B$ induces a map

$$
K^{\times} \backslash \widehat{K}^{\times} / \widehat{\mathcal{O}}_{M}^{\times} \longrightarrow B^{\times} \backslash \widehat{B}^{\times} / U
$$

Consider

$$
P_{\chi_{M}}\left(f_{M}\right)=\sum_{t \in \operatorname{Pic}\left(\mathcal{O}_{M}\right)} f_{M}(t) \chi_{M}(t)
$$

Denote by

$$
L^{\mathrm{alg}}(s, E)=L(s, E) / \Omega(E)
$$

where for any elliptic curve $A$ over $\mathbb{Q}, \Omega(A)$ is the real period for the Neron differential of $A$; and for simplicity, we let $\Omega=\Omega(E)$; then the imaginary period of $E$ is $\Omega^{-}=\Omega / \sqrt{-3}$.

Proposition 3.5. Up to $\pm 1, L^{\text {alg }}\left(1, E^{(M)}\right)=2^{-1} P_{\chi_{M}}\left(f_{M}\right)$.
Proof. By Theorem 2.16.

$$
L\left(1, E, \chi_{M}\right)=2^{-1} \frac{8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(36)}}{\sqrt{3} M} \frac{\left|P_{\chi_{M}}\left(f_{M}\right)\right|^{2}}{\left\langle f_{M}, f_{M}\right\rangle}
$$

Here,

$$
\left\langle f_{M}, f_{M}\right\rangle=\frac{\left\|f_{M}\right\|^{2}}{2} \operatorname{Vol}\left(X_{U}\right)
$$

and $\operatorname{Vol}\left(X_{U}\right)$ is the mass of $U$. By [3, Lemma 2.2],

$$
\operatorname{Vol}\left(X_{U}\right)=2\left(4 \pi^{2}\right)^{-1} \operatorname{Vol}(U)^{-1}
$$

where $\operatorname{Vol}(U)$ is with respect to Tamagawa measures so that for any finite $p \neq 3$, $\operatorname{Vol}\left(\mathrm{GL}_{2}\left(\mathbb{Z}_{p}\right)\right)=L\left(2,1_{p}\right)^{-1}, \operatorname{Vol}\left(\mathcal{O}_{B, 3}^{\times}\right)=2^{-1} L\left(2,1_{3}\right)^{-1}$. Therefore $\operatorname{Vol}\left(X_{U}\right)=4 / 3$, and $\left\langle f_{M}, f_{M}\right\rangle=2 / 3$. On the other hand,

$$
8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(36)}=8 \pi^{2} \int_{\Gamma_{0}(36) \backslash \mathcal{H}}|\phi(x+i y)|^{2} d x d y=i \Omega \Omega^{-}
$$

As $E^{(M)}$ and $E^{(-3 M)}$ are isogenous over $\mathbb{Q}, L\left(s, E, \chi_{M}\right)=L\left(s, E^{(M)}\right) L\left(s, E^{(-3 M)}\right)$ $=L\left(s, E^{(M)}\right)^{2}$. Denote by $\Omega^{(M)}$ the real period for $E^{(M)}$; then $\Omega^{(M)}=\Omega / \sqrt{M}$. Thus, $L^{\text {alg }}\left(1, E^{(M)}\right)^{2}=\left(L\left(1, E^{(M)}\right) / \Omega^{(M)}\right)^{2}=M L\left(1, E, \chi_{M}\right) / \Omega^{2}$ and

$$
L^{\mathrm{alg}}\left(1, E^{(M)}\right)^{2}=2^{-2}\left|P_{\chi_{M}}\left(f_{M}\right)\right|^{2}
$$

3.2. Rank zero twists. Keep the notation from the last section. Denote by $\mathscr{A}=$ $\operatorname{Gal}\left(H_{M} / K\right)$; then $2 \mathscr{A}=\operatorname{Gal}\left(H_{M} / H_{M}^{0}\right)$, where $H_{M}^{0}=K(\sqrt{q}: q \mid M)$. Let $\widehat{\mathscr{A}}$ (resp. $\widehat{\mathscr{A} / 2 \mathscr{A}}$ ) be a group of characters on $\mathscr{A}$ (resp. on $\mathscr{A}$ which factors through $2 \mathscr{A}$ ). Then

$$
\sum_{\chi \in \widehat{\mathscr{A} / 2 \mathscr{A}}} P_{\chi}\left(f_{M}\right)=2^{r} y_{0}, \text { where } y_{0}:=\sum_{\sigma \in 2 \mathscr{A}} f_{M}(\sigma) .
$$

Note that each $\chi \in \widehat{\mathscr{A} / 2 \mathscr{A}}$ corresponds to an integer $d \mid M$, in the sense that $\chi$ corresponds to the extension $K(\sqrt{d}) / K$.
Proposition 3.6. If $\chi \in \widehat{\mathscr{A} / 2 \mathscr{A}}$ corresponds to an integer $d \neq M$, then $P_{\chi}\left(f_{M}\right)=$ 0.

Proof. Choose a prime $q \in \mathbb{N}_{S}$ such that $q d \mid M$. Then

$$
\begin{aligned}
P_{\chi}\left(f_{M}\right) & =\sum_{\sigma \in \mathscr{A}} f_{M}(\sigma) \chi(\sigma) \\
& =\sum_{\sigma \in \operatorname{Gal}\left(H_{M / q} / K\right)} \sum_{\tau \in \operatorname{Gal}\left(H_{M} / H_{M / q}\right)} f_{M}(\sigma \tau) \chi(\sigma \tau) \\
& =\sum_{\sigma \in \operatorname{Gal}\left(H_{M / q} / K\right)} \chi(\sigma) \sum_{\tau \in \operatorname{Gal}\left(H_{M} / H_{M / q}\right)} f\left(\sigma \tau x_{M}\right) .
\end{aligned}
$$

By Theorem 2.18, we have

$$
u_{M / q} \sum_{\tau \in \operatorname{Gal}\left(H_{M} / H_{M / q}\right)} f\left(\sigma \tau x_{M}\right)=a_{q} f\left(\sigma x_{M / q}\right)=0 .
$$

So the proposition holds.
By Proposition 3.6, we have the equality

$$
P_{\chi_{M}}\left(f_{M}\right)=2^{r} y_{0}
$$

Lemma 3.7. The values of $\left.f_{M}\right|_{\widehat{B} \times 2}$ are odd. In particular, $y_{0}$ is odd and

$$
v_{2}\left(P_{\chi_{M}}\left(f_{M}\right)\right)=r .
$$

Proof. By the definition of $f_{M},\left.f_{M}\right|_{\widehat{B} \times 2}$ is odd if and only if for any $g \in \widehat{B}^{\times 2}$, $\chi_{0}\left(g x_{M}\right)=(-1)^{r}$. Since $\chi_{0}$ is quadratic, $\chi_{0}(g)=1$. Then $\chi_{0}\left(g x_{M}\right)=\chi_{0}\left(x_{M}\right)=$ $\prod_{i=1}^{r} \chi_{0}\left(x_{q_{i}}\right)=(-1)^{r}$ as $q_{i}$ is inert in $K$. Hence

$$
y_{0} \equiv\left[H_{M}: H_{M}^{0}\right] \equiv \frac{1}{3} \prod_{q \mid M} \frac{q+1}{2} \equiv 1(\bmod 2) .
$$

The Proof of Theorem 1.3, By Proposition [3.5], $v_{2}\left(L^{\mathrm{alg}}\left(1, E^{(M)}\right)\right)=r-1$. The 2-part of $B S D$ is equivalent to
$v_{2}\left(L^{\mathrm{alg}}\left(1, E^{(M)}\right)\right)=\sum_{p \mid 6 M} v_{2}\left(c_{p}\left(E^{(M)}\right)\right)-2 v_{2}\left(\# E_{\text {tor }}^{(M)}\right)+v_{2}\left(\# Ш\left(E^{(M)} / \mathbb{Q}\right)\right)$.
The Tamagawa numbers of $E^{(M)}$ are: $c_{2}\left(E^{(M)}\right)=3($ resp. $=1)$ if $M \equiv 1(\bmod 8)$ (resp. otherwise), $c_{3}\left(E^{(M)}\right)=2$ and $c_{q}\left(E^{(M)}\right)=2$ for $q \mid M$. On the other hand, $E^{(M)}(\mathbb{Q})=E^{(M)}(\mathbb{Q})_{\text {tor }}=\mathbb{Z} / 2 \mathbb{Z}$. Finally, using classical 2-descent, $\amalg\left(E^{(M)} / \mathbb{Q}\right)[2]$ $=0$. Combining the results above, it is clear that the 2-part of BSD conjecture holds.

By [15. Theorem 11.1], the $p$-part of the BSD-conjecture for $E^{(M)}$ holds for $p \nmid 6$, therefore the first part of Theorem 1.3 holds.
3.3. The Gross-Zagier formula. Let $K=\mathbb{Q}(\sqrt{-\ell})$ with $\ell \equiv 11(\bmod 12)$. Let $N=36$. Write $N=N_{0} N_{1}^{2}$ as before. There are two cases:
(1) if $\ell \equiv-1(\bmod 24)$, then the Heegner hypothesis holds and $N=N_{0}=36$;
(2) if $\ell \equiv 11(\bmod 24)$, then $N_{0}=9$.

Embed $K$ into $M_{2}(\mathbb{Q})$ as $i_{c}$ with $c=1$ in Example 2.1. Precisely, take an odd integer $a$ with $4 \cdot N_{0} \mid\left(\ell+a^{2}\right)$ and embed $K$ into $M_{2}(\mathbb{Q})$ by

$$
\sqrt{-\ell} \mapsto\left(\begin{array}{cc}
a & 2 \\
-\frac{\ell+a^{2}}{2} & -a
\end{array}\right)
$$

Then $M_{2}(\mathbb{Z}) \cap K=R_{0}\left(N_{0}\right) \cap K=\mathcal{O}_{K}$. Under such embedding, take $R=\mathcal{O}_{K}+$ $N_{1} R_{0}\left(N_{0}\right)$ and consider the modular curve $X_{K}(N)$. For the first case, $X_{K}(N)=$ $X_{0}(36)$. For the second case, the modular curve $X_{K}(N)$ has genus one and by Lemma 2.11 the cusp $[\infty]$ is defined over $\mathbb{Q}$. In fact, by [6, Example 11.7.c], $A:=\left(X_{K}(N),[\infty]\right)$ is the elliptic curve

$$
y^{2}=x^{3}-27 \quad(36 \mathrm{C})
$$

which is 3 -isogenous to $E$. We have $A(\mathbb{Q})=A(\mathbb{Q})[2] \cong \mathbb{Z} / 2 \mathbb{Z}$. For the first case (resp. the second case), take $f$ to be the identity morphism on $E$ (resp. on $A$ ). Denote by

$$
j=\left(\begin{array}{cc}
1 & 0 \\
-a & -1
\end{array}\right) \in K^{-}
$$

Lemma 3.8. Take $w \in \mathrm{GL}_{2}(\widehat{\mathbb{Q}})$ the Atkin-Lehner operator defined in Section 2.1, More precisely, for the Heegner hypothesis case, $w=j^{(36)} w_{2} w_{3}$ while for the second case, $w=j^{(3)} w_{3}$. Then $w$ normalizes $\widehat{R}^{\times}$and $w=t_{0} j u$ for some $t_{0} \in \widehat{K}^{\times}$and $u \in \widehat{R}^{\times}$. Moreover, $f+f^{w}$ is a constant map and its image is not in $2 E(\mathbb{Q})$ for the Heegner hypothesis case or not in $2 A(\mathbb{Q})=\{O\}$ for the other case.

Proof. By Lemma 2.12, it suffices to prove the "Moreover" part.
For the first case, denote by $\operatorname{Hom}_{[\infty]}\left(X_{0}(N), E\right)$ the space of $\mathbb{Q}$-morphisms from $X_{0}(N)$ to $E$ taking $[\infty]$ to $O$ and $\operatorname{Hom}_{[\infty]}^{0}\left(X_{0}(N), E\right)=\operatorname{Hom}_{[\infty]}\left(X_{0}(N), E\right) \otimes_{\mathbb{Z}} \mathbb{Q}$. By Atkin-Lehner theory, $f^{w}=-f$ in $\operatorname{Hom}_{[\infty]}^{0}\left(X_{0}(N), E\right)$. So $f^{w}+f$ is a constant map. However, $f([\infty])=O, f^{w}([\infty])=f([0])=[0]$, while [0] is the generator of $E(\mathbb{Q})=\mathbb{Z} / 6 \mathbb{Z}$. Thus, the image of $f+f^{w}$ is not in $2 E(\mathbb{Q})$.

For the second case, view $f \in \operatorname{Hom}_{[\infty]}^{0}\left(X_{K}(N), A\right)$. Then $f^{w_{3}}=\epsilon\left(A / \mathbb{Q}_{3}\right) f=f$. As $f$ and $f^{j_{2}}$ are both $K_{2}^{\times}$-invariant and such elements in $\operatorname{Hom}_{[\infty]}^{0}\left(X_{K}(N), A\right)$ form a $\mathbb{Q}$-vector space of dimension 1 , there is a sign $\epsilon \in\{ \pm 1\}$ such that $f^{j_{2}}=\epsilon_{2} f$. By [11, Theorem 4], the sign $\epsilon_{2}=+1$ if and only if $\epsilon\left(A / \mathbb{Q}_{2}\right)=\epsilon\left(A^{(-\ell)} / \mathbb{Q}_{2}\right)=1$. Since $\epsilon\left(A / \mathbb{Q}_{2}\right)=-1$, we obtain $f^{j_{2}}=-f$. Thus $f^{w}=-f$ and, as a morphism from $X_{K}(N)$ to $A, f+f^{w}=T$ for some torsion point $T \in A(\mathbb{Q})$. To see $T \neq O$, it suffices to show $[\infty] \neq[\infty]^{w}$. This is equivalent to saying that $w \notin P(\mathbb{Q}) \widehat{R}^{\times}$with $P$ the upper-triangular matrices in $\mathrm{GL}_{2}$. This holds since $w_{3} \notin P\left(\mathbb{Q}_{3}\right) R_{3}^{\times}$. In fact, $P\left(\mathbb{Q}_{3}\right) w_{3} \subset\left\{\left(\begin{array}{ll}a & b \\ c & 0\end{array}\right): b c \in \mathbb{Q}_{3}^{\times}\right\}$, while $R_{3}^{\times}=\left\{\left(\begin{array}{ll}a & b \\ c & d\end{array}\right) \in \mathrm{GL}_{2}\left(\mathbb{Z}_{3}\right): 9 \mid c\right\}$.

Write $\operatorname{Isom}_{\mathbb{Q}}(A)$ for the group of algebraic isomorphisms of $A$ over $\mathbb{Q}$ and $\operatorname{Aut}_{\mathbb{Q}}(A)$ the subrgroup of algebraic isomorphisms over $\mathbb{Q}$ which fix $O$. Then $\operatorname{Aut}_{\mathbb{Q}}(A)=$ $\mathbb{Z} / 2 \mathbb{Z}$ is generated by multiplication -1 and $\operatorname{Isom}_{\mathbb{Q}}(A)=\left\langle t_{T}\right\rangle \times \operatorname{Aut}_{\mathbb{Q}}(A)$ where $t_{T}: P \mapsto P+T$ the translation on $A$ by $T$.
Lemma 3.9. For any $P \in A, P^{w_{3}}=t_{T}(P)$ and $P^{j^{(3)}}=-P$.
Proof. In the above proof, we have seen that $w_{3} \notin P U_{3}$. Thus $[\infty]^{w_{3}} \neq[\infty]$. Hence for any point $P, P^{w_{3}}=t_{T}(P)$. On the other hand, $P^{w}=t_{T}(-P)$. Therefore, $P^{j^{(3)}}=\left(P^{w}\right)^{w_{3}^{-1}}=-P$.

Let $M=\prod_{i} q_{i}$ where $q_{i}$ are distinct positive integers $\equiv 5(\bmod 12)$. Denoted by $\chi_{M}$ the quadratic character of $K$ is associated to the extension $K(\sqrt{M}) / K$. Let $P_{M} \in X_{K}(N)\left(H_{M}\right)$ be the Heegner point defined in Subsection 2.3 Consider

$$
P_{\chi_{M}}(f)=\sum_{\sigma \in \operatorname{Gal}\left(H_{M} / K\right)} f\left(P_{M}\right)^{\sigma} \chi_{M}(\sigma) \in E(K) .
$$

Proposition 3.10. Up to $\pm 1$,

$$
L^{\mathrm{alg}}\left(1, E^{(M)}\right) \frac{L^{\prime}\left(1, E^{(-\ell M)}\right)}{\Omega\left(E^{(-\ell M)}\right)}=\widehat{h}_{K}\left(P_{\chi_{M}}(f)\right)
$$

Proof. By Theorem 2.14

$$
L^{\prime}\left(1, E, \chi_{M}\right)=\frac{8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(36)}}{\sqrt{\ell} M} \cdot \widehat{h}_{K}\left(P_{\chi_{M}}(f)\right)
$$

Since $L\left(s, E, \chi_{M}\right)=L\left(s, E^{(M)}\right) L\left(s, E^{(-\ell M)}\right)$, and we have proved that $L\left(s, E^{(M)}\right)$ is nonvanishing at $s=1$,

$$
L^{\prime}\left(1, E, \chi_{M}\right)=L\left(1, E^{(M)}\right) L^{\prime}\left(1, E^{(-\ell M)}\right)
$$

As in in the proof of Proposition 3.5

$$
8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(36)}=8 \pi^{2} \int_{\Gamma_{0}(36) \backslash \mathcal{H}}|\phi(x+i y)|^{2} d x d y=i \Omega \Omega^{-} .
$$

By [25], we know $\Omega\left(E^{(M)}\right)=\Omega / \sqrt{M}$ and up to $\operatorname{sign} \Omega\left(E^{(-\ell M)}\right)=\Omega^{-} / \sqrt{-\ell M}$, so up to sign

$$
\Omega\left(E^{(M)}\right) \Omega\left(E^{(-\ell M)}\right)=\frac{\Omega}{\sqrt{M}} \frac{\Omega^{-}}{\sqrt{-\ell M}}=-\frac{8 \pi^{2}(\phi, \phi)_{\Gamma_{0}(36)}}{M \sqrt{\ell}}
$$

thus up to sign:

$$
L^{\mathrm{alg}}\left(1, E^{(M)}\right) \frac{L^{\prime}\left(1, E^{(-\ell M)}\right)}{\Omega\left(E^{(-\ell M)}\right)}=\widehat{h}_{K}\left(P_{\chi_{M}}(f)\right) .
$$

3.4. Rank one twists. Let $\ell$ be a prime with $\ell \equiv 11(\bmod 12)$. Denote by $K=$ $\mathbb{Q}(\sqrt{-\ell})$. We only prove Theorem 1.2 in the case $\ell \equiv 11(\bmod 24)$, that is, 2 is inert in $K$ and 3 is split in $K$, while its proof for the other case is similar.

Let $M=q_{1} \cdots q_{r}$ where $q_{i}$ are distinct primes such that $q_{i} \equiv 5(\bmod 12)$ and inert in $K$. Denote by $\mathscr{A}=\operatorname{Gal}\left(H_{M} / K\right)$. Then $2 \mathscr{A}=\operatorname{Gal}\left(H_{M} / H_{M}^{0}\right)$, where $H_{M}^{0}=K(\sqrt{q}: q \mid M)$. Let $\widehat{\mathscr{A}}$ (resp. $\widehat{\mathscr{A} / 2 \mathscr{A})}$ ) be the group of characters on $\mathscr{A}$ (resp. on $\mathscr{A}$ which factors through $\left.\operatorname{Gal}\left(H_{M}^{0} / K\right)\right)$.

Let $A$ be the elliptic curve $y^{2}=x^{3}-27$. Observe that $A\left(H_{M}^{0}\right)\left[2^{\infty}\right]=A(\mathbb{Q})\left[2^{\infty}\right]=$ $A(\mathbb{Q})[2]$. In fact, suppose $Q \in A\left(H_{M}^{0}\right)\left[2^{\infty}\right]$ but $Q \notin A(\mathbb{Q})\left[2^{\infty}\right]$. Then the extension $\mathbb{Q}(Q) / \mathbb{Q}$ is unramified outside 2 and 3 . However, as $\mathbb{Q}(Q) \subset H_{M}^{0}, \mathbb{Q}(Q) / \mathbb{Q}$ must be ramified at $\ell$ or $q_{i}$ for some $i$. It's a contradiction. Let $T$ be the nontrivial element in $A(\mathbb{Q})[2]$, and let $C=\# A\left(H_{M}^{0}\right)_{\text {tor }} / 2$ be the cardinality of the odd part of $A\left(H_{M}^{0}\right)_{\text {tor }}$. Denote by

$$
y_{M}=P_{\chi_{M}}(f)=\sum_{\sigma \in \mathscr{A}} f\left(P_{M}\right)^{\sigma} \chi_{M}(\sigma) \in A\left(H_{M}^{0}\right)
$$

Similar to Proposition 3.6, we have

$$
y_{M}=2^{r} y_{0}, \text { where } y_{0}:=\sum_{\sigma \in 2 \mathscr{A}} f\left(P_{M}\right)^{\sigma},
$$

as an equality of divisors in $A\left(H_{M}^{0}\right)$. The key point is the following lemma:

## Lemma 3.11.

$$
\bar{y}_{0}+y_{0}=T .
$$

Proof. By Lemma 2.12, one can write $w=t_{0} j u$ with $t_{0} \in \widehat{K}^{\times}, j=K^{-}$and $u \in \widehat{R}^{\times}$. Take $x_{M} \in \widehat{B}^{\times}$as before such that $P_{M}=\left[h_{0}, x_{M}\right] \in X_{K}(N)\left(H_{M}\right)$ with $h_{0} \in \mathscr{H}^{K^{\times}}$. Thus, for any $\sigma_{t} \in 2 \mathscr{A}$ with $t \in \widehat{K}^{\times}$

$$
f^{w}\left(P_{M}\right)^{\sigma_{t}}=f\left(\left[h_{0}, t x_{M} t_{0} j\right]\right) .
$$

Note that $x_{M} \in \mathrm{GL}_{2}\left(\mathbb{Q}^{(N)}\right)$ while $t_{0} \in K_{(N)}^{\times} \subset \mathrm{GL}_{2}\left(\mathbb{Q}_{(N)}\right)$. Hence $x_{M} t_{0}=t_{0} x_{M}$ and

$$
f^{w}\left(P_{M}\right)^{\sigma_{t}}=f\left(\left[h_{0}, x_{M} j\right]\right)^{\sigma_{t t_{0}}} .
$$

Finally, we need to show that $x_{M} j \in j x_{M} U$. This reduces to show that for any $q \mid M$, the $q$-part of $x_{M}^{-1} j^{-1} x_{M} j$ belongs to $R_{q}^{\times}=\mathrm{GL}_{2}\left(\mathbb{Z}_{q}\right)$. It is easy to check this holds. Thus

$$
f^{w}\left(P_{M}\right)^{\sigma_{t}}=f\left(\left[h_{0}, j x_{M}\right]\right)^{\sigma_{t t_{0}}}={\overline{f\left(\left[h_{0}, x_{M}\right]\right)}}^{\sigma_{t t_{0}}} .
$$

On the other hand, note that in the proof of Lemma 2.12 $t_{0, p}=1$ for any $p \nmid N_{0}=9$. Denote by $a_{0}=N_{K / \mathbb{Q}}\left(t_{0}\right) \in \widehat{\mathbb{Q}}^{\times}$. Taking determinant for the equation $w=j t_{0} u$, we get $a_{0, p}=1$ if $p \neq 3$ and $a_{0,3} \in 9 \mathbb{Z}_{3}^{\times}$. Thus for any prime $q \mid M$

$$
\sigma_{t_{0}}(\sqrt{q})=\sigma_{a_{0}}(\sqrt{q})=\sqrt{q},
$$

where $\sigma_{a_{0}} \in \operatorname{Gal}(\mathbb{Q}(\sqrt{q}) / \mathbb{Q})$ via the Artin map over $\mathbb{Q}$. Hence, $\sigma_{t_{0}} \in 2 \mathcal{A}$.
Summing up, since $\left[H_{M}: H_{M}^{0}\right]=[H: K] \prod_{q \mid M} \frac{q+1}{2}$ is odd, we get

$$
\bar{y}_{0}+y_{0}=\sum_{\sigma \in 2 \mathscr{A}}\left(f+f^{w}\right)\left(P_{M}\right)^{\sigma}=\left[H_{M}: H_{M}^{0}\right] T=T .
$$

Theorem 3.12. $y_{M} \in A(K(\sqrt{M}))^{-}$and the 2-index of $y_{M}$ is $r-1$ in $A(K(\sqrt{M}))$. Proof. Consider the maps

where $\delta$ is the Kummer map, which is injective, and the horizontal line is the inflation-restriction exact sequence. Since $y_{M}=2^{r} y_{0}$ with $y_{0} \in A\left(H_{M}^{0}\right)$, the image of $\delta\left(y_{M}\right)$ is 0 in $H^{1}\left(H_{M}^{0}, A\left[2^{r}\right]\right)$, hence we see that $\delta\left(y_{M}\right)$ lies in the image of $H^{1}\left(H_{M}^{0} / K(\sqrt{M}), A\left[2^{r}\right]\left(H_{M}^{0}\right)\right)$, which is killed by 2 . It follows that $2 y_{M} \in$ $2^{r} A(K(\sqrt{M}))$; then

$$
y_{M}=2^{r-1} z+t, z=2 y_{0}+s
$$

for some $z \in A(K(\sqrt{M}))$ and $s, t \in A(\mathbb{Q})[2]$.
Let $\sigma \in \operatorname{Gal}(K(\sqrt{M}) / K)$ be the nontrivial element. Then by definition, we have $y_{M}+y_{M}^{\sigma}=0$, so $y_{0}+y_{0}^{\sigma} \in A\left(H_{M}^{0}\right)\left[2^{r}\right]=A(\mathbb{Q})[2]$, so $z+z^{\sigma}=0$. On the other hand

$$
z+\bar{z}=2\left(y_{0}+\bar{y}_{0}\right)=0,
$$

which implies $z \in A(\mathbb{Q}(\sqrt{-\ell M}))^{-}=A^{(-\ell M)}(\mathbb{Q})$. Therefore

$$
y_{M} \in 2^{r-1} A(\mathbb{Q}(\sqrt{-\ell M}))^{-}+A(\mathbb{Q})[2] .
$$

We will show that the 2-index of $y_{M}$ is exactly $r-1$. Suppose that $y_{M}=2^{r} z+t$ for some $z \in A(\mathbb{Q}(\sqrt{-\ell M}))^{-}$and $t \in A(\mathbb{Q}(\sqrt{-\ell M}))_{\text {tor }}$. Then $2^{r}\left(z-y_{0}\right)+t=0$, which implies $C\left(z-y_{0}\right) \in A(\mathbb{Q})[2]$. Hence $C\left(z-y_{0}\right)+C\left(\bar{z}-\bar{y}_{0}\right)=0$. But we have $z+\bar{z}=0$, so $C\left(y_{0}+\bar{y}_{0}\right)=0$. But this contradicts the fact that $\bar{y}_{0}+y_{0}=T \neq 0$.

The Proof of Theorem 1.2, Observe that $A$ and $E$ are 3-isogenuous, so to prove Theorem 1.2 we only need to prove that it holds for $A$.

By Proposition 3.10, up to $\pm 1$,

$$
L^{\mathrm{alg}}\left(1, A^{(M)}\right) \frac{L^{\prime}\left(1, A^{(-\ell M)}\right)}{\Omega\left(A^{(-\ell M)}\right)}=\widehat{h}_{K}\left(y_{M}\right)
$$

Denote by $R(-\ell M)=\widehat{h}\left(P_{-\ell M}\right)$ where $P_{-\ell M}$ is the generator of $A^{(-\ell M)}(\mathbb{Q}) /$ $A^{(-\ell M)}(\mathbb{Q})_{\text {tor }}$. In particular, by Theorem 3.12

$$
\widehat{h}_{K}\left(y_{M}\right)=2^{2(r-1)} R(-\ell M) .
$$

Thus, if we denote by

$$
L^{\prime} \operatorname{alg}\left(s, A^{(-\ell M)}\right)=\frac{L^{\prime}\left(s, A^{(-\ell M)}\right)}{R(-\ell M) \Omega\left(A^{(-\ell M)}\right)}
$$

then by the result of the rank zero case, we have

$$
v_{2}\left(L^{\prime \operatorname{alg}}\left(1, A^{(-\ell M)}\right)\right)=r .
$$

The Tamagawa numbers of $A^{(-\ell M)}$ are: $c_{2}\left(A^{(-\ell M)}\right)=1$ or $3, c_{3}\left(A^{(-\ell M)}\right)=2$ and $c_{q}\left(A^{(-\ell M)}\right)=2$ for $q \mid \ell M$. On the other hand, $A^{(-\ell M)}(\mathbb{Q})=A^{(-\ell M)}(\mathbb{Q})_{\text {tor }}=$ $\mathbb{Z} / 2 \mathbb{Z}$. Finally, using classical 2-descent, $\amalg\left(A^{(-\ell M)} / \mathbb{Q}\right)[2]=0$. Combining the results above, it is clear that the 2-part of BSD conjecture for $A^{(-\ell M)}$ holds.

Since $A^{(-\ell M)}$ has CM, the $p$-adic height pairing on $A^{(-\ell M)}(\overline{\mathbb{Q}})$ is nondegenerate. Then by [12, Corollary 1.9], $p$-part of the BSD conjecture for $A^{(-\ell M)}$ holds for $p \nmid 6 \ell M$. So the second part of Theorem 1.2 holds for $A$, and hence for $E$.

## Acknowledgment

The authors greatly thank Professor Ye Tian for suggesting this problem and his persistent encouragement.
