Michelle Chu* (michu@uic.edu) and **Alexander Kolpakov**. *Counting hyperbolic manifolds which bound geometrically.*

A hyperbolic n -manifold is said to bound geometrically if it is isometric to the boundary of a hyperbolic $(n+1)$ -manifold with totally geodesic boundary. We might expect that most hyperbolic manifolds will not bound geometrically, and if they do then their volumes should be quite big. In this talk I will discuss how the number of arithmetic hyperbolic manifolds which bound geometrically grows with volume. This is joint work with Sasha Kolpakov. (Received August 29, 2019)
