SHORTER NOTICES

Sur les Espaces à Structure Uniforme et sur la Topologie Générale. By André Weil.
Paris, Hermann, 1937. 39 pp.

A space E with uniform structure is a topological space restricted as follows.
There exists on E a system of neighborhoods $V_\alpha(p)$, one for each point p of E and
each α in a nonvacuous set of values. Four conditions are fulfilled: (1) For every
(p, α), p is on $V_\alpha(p)$. (2) For any (p, q) distinct in E, there exists an α such that q
is not on $V_\alpha(p)$. (3) For any two indices (α, β), there exists an index γ such that, for
every p, $V_\gamma(p)$ is on the common part of $V_\alpha(p)$ and $V_\beta(p)$. (4) For every α there is a
β such that if (p, q) are both on $V_\beta(r)$, then q is on $V_\alpha(p)$. The author of the book
formulates these conditions as three axioms, combining (1) and (2). Any system
$V'_\lambda(p)$ determines the same uniform structure in E provided each $V_\alpha(p)$ contains a
$V'_\lambda(p)$ and vice versa. The spaces with uniform structure are those in which uniform
continuity has meaning. They are completely regular and they include all metric
spaces and all topologic groups, whether metrisable or not. The article under con-
sideration contains proofs for uniform spaces of a number of results previously
established only with the aid of a metric. The source of these results is seen to inhere
in the possibility of certain comparisons of neighborhoods in different parts of a
uniform space. The work includes an extension theorem for uniformly continuous
functions, a discussion of compact and locally compact spaces with regard to their
uniform structure, and a number of group theoretic applications. There is also, at
the start, a severe criticism of the role often played by the hypothesis that a space be
separable. The author characterizes this hypothesis as an evil parasite which infests
many works, lessening their scope and their clarity. The book terminates with a few
interesting "observations on topologic axioms," in which an attempt is made to
distinguish between those axioms having only a historic interest and those truly
important in the development of topology.

Introduction Mathématique aux Théories Quantiques. Part 2. By Gaston Julia.
(Cahiers Scientifiques, vol. 19.) Paris, Gauthier-Villars, 1938. 6+220 pp.

The present volume is the second of a series in which Julia develops the theory
of unitary spaces and Hilbert space. It is based on a sequence of lectures begun in
1935. After dealing with unitary spaces in his first volume, Julia turns here to the
study of Hilbert space. He divides the discussion into five chapters, as follows:
Section I. Hilbert space: Chapter 1, Vectorial analytic representation of Hilbert
space. Geometrical study. Chapter 2, Functional analytic representation of Hilbert
space. Chapter 3, Axiomatic study of Hilbert space. Axiomatic definition of Hilbert
space. Section II. Linear transformations or operators in Hilbert space: Chapter 4,
Linear operators. General properties. Representation and algebraic calculus of oper-
ators. Chapter 5, Inversion of bounded linear operators. Resolution of infinite
systems of linear equations in Hilbert space.

The separate study of the spaces $\mathfrak{H}_0$ and $\mathfrak{L}_2$ on their own merits in the first two
chapters is followed by the unification of their properties under the abstract or
axiomatic point of view in the third chapter. The fundamental definitions and
