# SPACE CREMONA TRANSFORMATIONS OF ORDER $m+n-1^{1}$ 

EDWIN J. PURCELL

1. Introduction. This paper discusses a space Cremona transformation of order $m+n-1$ ( $m, n$ any integers) generated by two rational twisted curves. One special position of the defining curves gives rise to an involution recently described, ${ }^{2}$ while another special position results in an involution somewhat similar to one which was defined in a different manner by Montesano. ${ }^{3}$
2. Cremona transformation. Consider a curve $C_{n}$ of order $n$ having $n-1$ points on each of two skew lines $d$ and $d^{\prime}$, and a curve $C_{m}{ }^{\prime}$ of order $m$ having $m-1$ points on each of $d$ and $d^{\prime}(m, n$, any integers). A generic point $P$ determines a ray through it intersecting $C_{n}$ once in $\alpha$ and $d$ once in $\beta . P$ also determines a ray through it intersecting $C_{m}{ }^{\prime}$ once in $\gamma$ and $d$ once in $\delta$. We define $P^{\prime}$, the correspondent of $P$, to be the intersection of lines $\alpha \delta$ and $\beta \gamma$.

It is to be noted that if $C_{n}$ should become identical with $C_{m}{ }^{\prime}$ but $d$ and $d^{\prime}$ remain distinct, there would result the Cremona involution we discussed in a recent paper (loc. cit.).

Let the equations of $d$ be $x_{1}=0, x_{2}=0$, and those of $d^{\prime}$ be $x_{3}=0$, $x_{4}=0$. Let $C_{n}$ be

$$
\begin{array}{ll}
x_{1}=(a s+b t) \prod_{1}^{n-1}\left(t_{i} s-s_{i} t\right), & x_{2}=(c s+d t) \prod_{1}^{n-1}\left(t_{i} s-s_{i} t\right) \\
x_{3}=(e s+f t) \prod_{n}^{2 n-2}\left(t_{i} s-s_{i} t\right), & x_{4}=(g s+h t) \prod_{n}^{2 n-2}\left(t_{i} s-s_{i} t\right)
\end{array}
$$

where $s_{i}, t_{i}$ for $i=1,2, \cdots, n-1$ are values of the parameters of $C_{n}$ for points on $d$, and for $i=n, n+1, \cdots, 2 n-2$, for points on $d^{\prime}$.

Let the equations of $C_{m}{ }^{\prime}$ be

$$
\begin{aligned}
& x_{1}=(A S+B T) \prod_{1}^{m-1}\left(T_{i} S-S_{i} T\right), \quad x_{2}=(C S+D T) \prod_{1}^{m-1}\left(T_{i} S-S_{i} T\right), \\
& x_{3}=(E S+F T) \prod_{m}^{2 m-2}\left(T_{i} S-S_{i} T\right), \quad x_{4}=(G S+H T) \prod_{m}^{2 m-2}\left(T_{i} S-S_{i} T\right)
\end{aligned}
$$

[^0]where $S_{i}, T_{i}$ for $i=1,2, \cdots, m-1$ are values of the parameters of $C_{m}{ }^{\prime}$ for points on $d$, and for $i=m, m+1, \cdots, 2 m-2$, for points on $d^{\prime}$. Then the equations of the transformation are
\[

$$
\begin{aligned}
& x_{1}^{\prime}=k\left(Q_{1} x_{3}+Q_{2} x_{4}\right)\left(\prod_{1}^{n-1} \theta_{i}\right)\left(\prod_{1}^{m-1} \Phi_{i}\right), \\
& x_{2}^{\prime}=k\left(R_{1} x_{3}+R_{2} x_{4}\right)\left(\prod_{1}^{n-1} \theta_{i}\right)\left(\prod_{1}^{m-1} \Phi_{i}\right), \\
& x_{3}^{\prime}=K^{\prime}\left(r_{2} x_{1}-q_{2} x_{2}\right)\left(\prod_{n}^{2 n-2} \theta_{i}\right)\left(\prod_{m}^{2 m-2} \Phi_{i}\right) \\
& x_{4}^{\prime}=K^{\prime}\left(q_{1} x_{2}-r_{1} x_{1}\right)\left(\prod_{n}^{2 n-2} \theta_{i}\right)\left(\prod_{m}^{2 m-2} \Phi_{i}\right),
\end{aligned}
$$
\]

where $k \equiv(b c-a d), K^{\prime} \equiv(F G-E H)$, and

$$
\begin{array}{rlrl}
Q_{1} & \equiv(A H-B G), & & Q_{2} \equiv(B E-A F) \\
R_{1} & \equiv(C H-D G), & & R_{2} \equiv(D E-C F) \\
q_{1} & \equiv(a h-b g), & & q_{2} \equiv(b e-a f) \\
r_{1} & \equiv(c h-d g), & & r_{2} \equiv(d e-c f) \\
\theta_{i} & \equiv\left\{t_{i}\left(b x_{2}-d x_{1}\right)-s_{i}\left(c x_{1}-a x_{2}\right)\right\} \\
\Phi_{i} & \equiv\left\{T_{i}\left(H x_{3}-F x_{4}\right)-S_{i}\left(E x_{4}-G x_{3}\right)\right\}
\end{array}
$$

The inverse transformation is

$$
\begin{aligned}
& x_{1}=K\left(q_{1} x_{3}^{\prime}+q_{2} x_{4}^{\prime}\right)\left(\prod_{1}^{n-1} \phi_{i}^{\prime}\right)\left(\prod_{1}^{m-1} \Theta_{i}^{\prime}\right) \\
& x_{2}=K\left(r_{1} x_{3}^{\prime}+r_{2} x_{4}^{\prime}\right)\left(\prod_{1}^{n-1} \phi_{i}^{\prime}\right)\left(\prod_{1}^{m-1} \Theta_{i}^{\prime}\right) \\
& x_{3}=k^{\prime}\left(R_{2} x_{1}^{\prime}-Q_{2} x_{2}^{\prime}\right)\left(\prod_{n}^{2 n-2} \phi_{i}^{\prime}\right)\left(\prod_{m}^{2 m-2} \Theta_{i}^{\prime}\right), \\
& x_{4}=k^{\prime}\left(Q_{1} x_{2}^{\prime}-R_{1} x_{1}^{\prime}\right)\left(\prod_{n}^{2 n-2} \phi_{i}^{\prime}\right)\left(\prod_{m}^{2 m-2} \Theta_{i}^{\prime}\right),
\end{aligned}
$$

where $K \equiv(B C-A D), k^{\prime} \equiv(f g-e h)$,

$$
\begin{aligned}
\phi_{i}^{\prime} & \equiv\left\{t_{i}\left(h x_{3}^{\prime}-f x_{4}^{\prime}\right)-s_{i}\left(e x_{4}^{\prime}-g x_{3}^{\prime}\right)\right\} \\
\Theta_{i}^{\prime} & \equiv\left\{T_{i}\left(D x_{1}^{\prime}-B x_{2}^{\prime}\right)-S_{i}\left(A x_{2}^{\prime}-C x_{1}^{\prime}\right)\right\}
\end{aligned}
$$

Both the direct and inverse transformations are of order $m+n-1$, where $m$ and $n$ are any integers.

The fundamental system and its images for the direct transformation are as follows.
$d$ is an $(n-1)$-fold $F$-line of simple contact. The fixed tangent planes are $\theta_{i}=0$, where $i=1,2, \cdots, n-1$. It is of the first species and its $P$-surface consists in the planes $\phi_{i}^{\prime}=0$, where $i=1,2, \cdots$, $n-1$, which pass through $d^{\prime}$.
$d^{\prime}$ is an ( $m-1$ )-fold $F$-line of simple contact. The fixed tangent planes are $\Phi_{i}=0$, where $i=m, m+1, \cdots, 2 m-2$. It is of the first species and its $P$-surface consists in the $m-1$ planes $\Theta_{i}^{\prime}=0$ through $d$, where $i=m, m+1, \cdots, 2 m-2$.

Each of the $m-1$ intersections of $C_{m}{ }^{\prime}$ and $d$ is an $n$-fold isolated $F$-point. Their $P$-surfaces are $\Theta_{i}^{\prime}=0$, where $i=1,2, \cdots, m-1$, respectively.

Each of the $n-1$ intersections of $C_{n}$ and $d^{\prime}$ is an $m$-fold isolated $F$-point. Their $P$-surfaces are $\phi_{i}^{\prime}=0(i=n, n+1, \cdots, 2 n-2)$ respectively.

The $(n-1)(m-1)$ lines of intersection of the $n-1$ fixed tangent planes through $d$ with the $m-1$ fixed tangent planes through $d^{\prime}$ are simple $F$-lines without contact. They are of the second species.

The $(m-1)(n-1)$ lines joining the $m-1 n$-fold isolated $F$-points on $d$ with the $n-1 m$-fold isolated $F$-points on $d^{\prime}$ are simple $F$-lines without contact. They are of the second species.

We may obtain a description of the fundamental system of the inverse transformation by interchanging $m$ and $n, C_{n}$ and $C_{m}{ }^{\prime}, \theta_{i}$ and $\Theta_{i}^{\prime}, \Phi_{i}$ and $\phi_{i}^{\prime}$, wherever they appear in the foregoing.
$C_{n}, d$, and $d^{\prime}$ lie on the same quadric surface $Q$, and $C_{m}{ }^{\prime}, d$, and $d^{\prime}$ lie on a quadric surface $Q^{\prime}$. These quadrics may be the same or distinct and, while this does not affect the preceding discussion, the invariant systems for the two cases are different.

When $Q$ and $Q^{\prime}$ are distinct, they intersect in $d, d^{\prime}$, and two transversals $l_{1}$ and $l_{2}$. The $d$ and $d^{\prime}$ are common generators of the $\mu$-systems of the two quadrics, while $l_{1}$ and $l_{2}$ are common generators of their $\lambda$-systems. The transformation sends each $\lambda$-generator of $Q$ over into a $\lambda$-generator of $Q^{\prime}$, and each $\lambda$-generator of $Q^{\prime}$ over into a $\lambda$-generator of $Q$. Thus $Q$ as a whole corresponds to $Q^{\prime}$ and vice versa. Each $\lambda$-generator of either quadric belongs to a cycle of index four-that is, four applications of the transformation leave every $\lambda$-generator invariant. The transformation interchanges $C_{n}$ and $C_{m}{ }^{\prime}$. The points of $l_{1}$ are in involution; thus $l_{1}$ is an invariant line and the two fixed points of the involution are invariant points. Similarly for $l_{2}$. These four invariant points are the only invariant points that are not also $F$-points.

Let us now consider the case where $C_{n}, C_{m}{ }^{\prime}, d$, and $d^{\prime}$ all lie on the
same quadric $Q \equiv x_{1} x_{4}-x_{2} x_{3}=0$. The transformation causes $C_{n}$ and $C_{m}{ }^{\prime}$ to interchange. The pencil of planes $x_{4}-\lambda x_{3}=0$ is in involution with the pencil $x_{2}-\lambda x_{1}=0$ and this makes each $\lambda$-generator of $Q$ invariant. Consequently $Q$ is invariant. The locus of invariant points is a curve $K_{m+n}$ of order $m+n$ lying on $Q . K_{m+n}$ passes through the $m+n-2$ points of intersection of $C_{n}$ and $C_{m}{ }^{\prime}$ and intersects $d$ and $d^{\prime}$ in the $m+n-2$ isolated $F$-points on each of them. It intersects every $\mu$-generator of $Q$ in $m+n-2$ points and intersects every $\lambda$-generator in two points.
3. Involution. Consider a twisted curve $C_{n}$ having $n-1$ points $\Delta_{i}$ on a straight line $d$, and a curve $C_{m}{ }^{\prime}$ having $m-1$ points $\Sigma_{i}$ on the same straight line $d$ ( $m, n$ any integers). A generic point $P$ determines a ray through it intersecting $C_{n}$ in $\alpha$ and $d$ in $\beta$, and also a ray through it intersecting $C_{m}{ }^{\prime}$ in $\gamma$ and $d$ in $\delta$. We define $P^{\prime}$, the correspondent of $P$ in the involution, to be the intersection of lines $\alpha \delta$ and $\beta \gamma$.

If, in §2, we make $d$ and $d^{\prime}$ identical, we obtain an involution of this kind. However, the curves $C_{n}$ and $C_{m}{ }^{\prime}$ of the present section do not necessarily lie on quadric surfaces.

The involution is of order $m+n-1$.
The fundamental system and its principal images follow.
$d$ is an $(n+m-2)$-fold $F$-line of simple contact. The fixed tangent planes are $\theta_{i}=0$, where $i=1,2, \cdots, n-1$, and $\Theta_{i}=0$, where $i=1,2, \cdots, m-1$. It is of the second species and counts $(n+m-1)$ $\cdot(n+m-2)$ times in the intersection of any two homaloids.

Points $\Delta_{i}$ are isolated $F$-points. Their $P$-surfaces are the planes $\theta_{i}=0(i=1,2, \cdots, n-1)$ respectively.

Points $\Sigma_{i}$ are isolated $F$-points. The $P$-element of each is $\Theta_{i}=0$ ( $i=1,2, \cdots, m-1$ ) respectively.

As we have seen, a general point $P$ determines with $d$ a plane $\pi$ intersecting $C_{n}$ in $\alpha$ and $C_{m}{ }^{\prime}$ in $\gamma$. Call $L$ the intersection of lines $\alpha \gamma$ and $d$. Then $J$, the harmonic conjugate of $L$ with respect to $\alpha$ and $\gamma$, will be the only invariant point of $\pi$ other than points of $d$. As $\pi$ makes one revolution about $d, \alpha$ moves in $\pi$ and crosses $d n-1$ times; $\gamma$ also moves in $\pi$, crossing $d m-1$ times. As $\alpha$ approaches $d$, $J$ approaches the same point on $d$, and the locus of $J$ intersects $d$ in all the points $d$ has in common with $C_{n}$ and $C_{m}{ }^{\prime}$. The locus of $J$ is a rational curve $K_{m+n-1}$ of order $m+n-1$ having $m+n-2$ points on $d . K_{m+n-1}$ is the locus of invariant points.

It is clear that the line $P P^{\prime}$ intersects $K_{m+n-1}$ in $J$ and $d$ in $L$, and that $P$ and $P^{\prime}$ are harmonic conjugates with respect to ${ }^{4} J$ and $L$.

[^1]4. Lower order for particular positions of the defining elements. Each of the fixed tangent planes $\theta_{i}=0$ mentioned in the contact conditions for the involution passes through $d$ and is tangent to $C_{n}$ at the corresponding $\Delta_{i}$. The fixed tangent planes $\Theta_{i}=0$ are similarly related to the curve $C_{m}{ }^{\prime}$.

If $C_{n}$ and $C_{m}{ }^{\prime}$ are so situated that a plane of $\theta_{i}=0(i=1,2, \cdots, n-1)$ coincides with a plane of $\Theta_{i}=0(i=1,2, \cdots, m-1)$, the order of the involution is reduced by one. In this way we may reduce the order by any integer up to, and including, the smaller of the two numbers $n-1$ and $m-1$.
