\mathbb{C}^* -ACTIONS ON \mathbb{C}^3 ARE LINEARIZABLE

S. KALIMAN, M. KORAS, L. MAKAR-LIMANOV, AND P. RUSSELL

(Communicated by Hyman Bass)

ABSTRACT. We give the outline of the proof of the linearization conjecture: every algebraic \mathbb{C}^* -action on \mathbb{C}^3 is linear in a suitable coordinate system.

1. Introduction

The purpose of this note is to outline the main ingredients in a proof of the following

Linearization Theorem. Every algebraic action of the torus $T = \mathbb{C}^*$ on affine space $X = \mathbb{C}^3$ is linearizable, that is linear in suitably chosen coordinates for X.

It is known that the action has a fixpoint $0 \in X$ ([B-B]). The weights of the action are the weights

$$a_1, a_2, a_3$$

of the (diagonalized) action on the tangent space T_0X . (They are independent of the choice of fixpoint [KbR].) We will assume tacitly that the action is effective, or, equivalently, that $GCD(a_1, a_2, a_3) = 1$. Put

$$\delta = \dim X//T, \quad \tau = \dim X^T.$$

Then $2 \ge \delta \ge \tau \ge 0$.

It is known that *fixpointed* actions, that is those for which all weights have the same sign, are linearizable [KbR]. This settles the following cases:

 $\delta = 0 = \tau$, or three nonzero weights of the same sign;

 $\delta = 1 = \tau$, or one zero weight, two nonzero weights of the same sign;

 $\delta = 2 = \tau$, or two zero weights, one nonzero weight.

The case

 $\delta = 2, \tau = 1$, or one zero weight, two nonzero weights of opposite sign, was settled in [KR1].

It remains to consider the

Hyperbolic Case. $\delta = 2, \tau = 0$, or three nonzero weights, not all of the same sign.

A program to settle this case was proposed in [KR2]. It has two quite distinct components.

Step I, the quotient. Show that X//T is as expected for a linear action, i.e.

$$X//T \simeq T_0 X//T$$
.

Let $\omega_{\alpha} \subset \mathbb{C}^*$ be the group of α -roots of 1. Linearizability follows from Step I (see 1.4 below) in the case dim $X^{w_{\alpha}} \leq 1$ for all $\alpha > 1$, or equivalently, if the weights are pairwise relatively prime. This leads to

 $Step\ II$, reduction of weights. Reduction of the proof to the case of pairwise relatively prime weights.

If $\alpha > 1$ and α divides two weights, then $X' = X/\omega_{\alpha}$ is a smooth, affine threefold, but only after linearizability has been established is it at all clear that $X' \simeq \mathbb{C}^3$. We are therefore led to study more general \mathbb{C}^* -threefolds.

- 1.1. **Standard conditions.** Let X be a \mathbb{C}^* -threefold. We consider the following conditions.
 - (i) X is smooth and the action of $T = \mathbb{C}^*$ is hyperbolic,

i.e. there is a unique fixpoint 0 and dim X//T=2.

- (ii) X is contractible.
- (iii) $\overline{\kappa}(X) = -\infty$ ($\overline{\kappa} = \text{logarithmic Kodaira dimension}$).

If we have 1.1 (i), the weights of the action are defined as above for $X = \mathbb{C}^3$, and we assume

$$a_1 < 0, \ a_2 > 0, \ a_3 > 0, \qquad GCD(a_1, a_2, a_3) = 1.$$

We put

$$\alpha_i = GCD(\{a_1, a_2, a_3\} - \{a_i\}).$$

Then

$$-a_1 = a\alpha_2\alpha_3$$
, $a_2 = b\alpha_1\alpha_3$, $a_3 = c\alpha_1\alpha_2$

with a, b, c > 0 and reduced (pairwise relatively prime).

- **1.2.** Proposition ([KR3], 2.5). Let X satisfy 1.1 (i).
 - (i) Suppose $\alpha_i > 1$. Then dim $X^{\omega_{\alpha_i}} = 2$ and

$$X' = X/\omega_{\alpha_i}$$

satisfies 1.1 (i) for $T' = T/\omega_{\alpha_i} \simeq \mathbb{C}^*$ with weights a_i and a_j/α_i for $j \neq i$.

- (ii) $X^{\#} = X/\omega_{\alpha_1\alpha_2\alpha_3}$ satisfies 1.1 (i) for $T^{\#} = T/\omega_{\alpha_1\alpha_2\alpha_3} \simeq \mathbb{C}^*$ and reduced weights -a, b, c.
 - (iii) $X//T = X'//T' = X^{\#}//T^{\#}$.
 - (iv) If X satisfies 1.1 (ii) or (iii), then so do X' and $X^{\#}$.

Let X satisfy 1.1 (i) and (ii). We put ([KR3], 1.4)

$$X^+ = \{x \in X | \lim_{t \to 0} t \cdot x = 0\}.$$

Then $X^+ \simeq \mathbb{C}^2$ and $X^+ = F^{-1}(0)$, where F is semiinvariant of weight a_1 . ω_{a_1} acts on

$$X_1 = F^{-1}(1)$$

and we have ([KR1], Lemma 2)

1.3. $X//T \simeq X_1/w_{a_1}$.

The reduction of the proof to Steps I and II is now contained in

1.4. Proposition ([KR3], 2.3, 2.8, and 1.10). Let X satisfy 1.1 (i) and (ii) and suppose the weights are reduced. If

$$X//T \simeq T_0 X//T$$
,

or equivalently

$$X_1/\omega_a \simeq \mathbb{C}^2/\omega_a$$

where ω_a acts diagonally on \mathbb{C}^2 with weights $\equiv b, c \mod a$, then

$$X_1 \simeq \mathbb{C}^2$$
,

and

$$X \simeq_e \mathbb{C}^3$$

(X is equivariantly isomorphic to $\mathbb{C}^3 = T_0 X$).

2. The quotient

2.1. Theorem ([KR4], 1.2). Suppose X satisfies all conditions of 1.1. Then

$$S' = X//\mathbb{C}^* \simeq T_0 X//\mathbb{C}^*.$$

By 1.2, we may assume the weights are reduced when studying the quotient. Also, 2.1 is known ([KR2]) when S' is smooth, or equivalently a=1. So we assume a>1. Then by [KR4], 2.4

- 2.2. S' is contractible, $\overline{\kappa}(S') = -\infty$, S' has a unique singular point q, q is analytically of the type of the origin in \mathbb{C}^2/ω_a , and $\mathrm{Pic}(S'-q) \simeq \mathbb{Z}/a\mathbb{Z}$.
- **2.3. Theorem** ([K]). If S' is as in 2.2, then
 - (i) if $\overline{\kappa}(S'-q) = -\infty$, then $S' \simeq \mathbb{C}^2/\omega_a$,
 - (ii) $\overline{\kappa}(S'-q) \neq 0, 1$.

It remains to rule out $\overline{\kappa}(S'-q)=2$ to complete Step I.

2.4. Theorem ([KR4], 1.1). Let

$$S' = X//T$$

with X satisfying all conditions of 1.1. Then

$$\overline{\kappa}(S'-q)<2.$$

The proof is rather involved. It relies in a crucial way on the theory of open algebraic surfaces, in particular the inequalities of Miyaoka [M] and Kobayashi [Ko] and the results on the existence of affine rulings of Miyanishi and Tsunoda [MT].

2.5. Proposition ([KR4], 2.8). Let S' be as in 2.4. There exists a desingularization S of S' admitting an \mathbb{A}^1 -ruling with all but one component E of the exceptional locus \hat{E} in fibres. Moreover, $S - \Delta$ is simply connected, where $\Delta = \hat{E} - E$.

The proof of 2.4 proceeds by a detailed analysis of such "good" rulings under the conditions of 2.2.

3. Reduction of Weights and "Exotic Affine Spaces"

Step II, the reduction of weights, is achieved in a roundabout way. In [KR3], an explicit construction is given of a class of smooth, contractible \mathbb{C}^* -threefolds that encompasses, in the equivariant sense, all possible counterexamples to linearization. It is then shown in [KM-L] that only the "obviously" equivariantly trivial threefolds in the class are isomorphic to \mathbb{C}^3 (without reference to the \mathbb{C}^* -action). The others are in themselves interesting examples of "exotic affine spaces" (algebraic varieties homeomorphic to \mathbb{C}^3). They include the threefolds described in [D], 4.36.

3.1. Theorem ([KR3], 4.1). The threefolds

$$X = \operatorname{Spec} A$$

satisfying 1.1 (i) and (ii) and

$$X//\mathbb{C}^* \simeq T_0 X//\mathbb{C}^*$$

are precisely the ones obtained as follows.

(1) Let

$$-a = a_1', b = a_2', c = a_3'$$

be a triple of reduced weights with a,b,c>0. (These define a hyperbolic \mathbb{C}^* -action on

$$W=\operatorname{Spec} B\simeq \mathbb{C}^3$$

with $B = \mathbb{C}[\eta, \xi, \zeta]$ and η, ξ, ζ homogeneous of weight -a, b, c).

(2) Let

$$\alpha_1, \alpha_2, \alpha_3$$

be a reduced triple of positive integers with $GCD(\alpha_i, a_i') = 1, i = 1, 2, 3.$

- (3) Let C_2 and C_3 be ω_a -homogeneous "lines" (curves isomorphic to \mathbb{C}) in $W_1 = \operatorname{Spec} k[\xi, \zeta] \simeq \mathbb{C}^2$, identified with $\eta^{-1}(1) \subset W$, such that
 - (i) C_2 and C_3 meet normally in $r \geq 1$ points, including the origin,
 - (ii) $U_i = \overline{\mathbb{C}^* \cdot C_i} \subset W$ is smooth, i = 2, 3.
 - (4) Let $U_1 = W^+ = \eta^{-1}(0)$.

Then X is the "tri-cyclic" cover of W ramified to order α_i over U_i , i = 1, 2, 3, that is,

$$A = B[z_1, z_2, z_3],$$

where $z_i^{\alpha_i} = u_i$ with $u_1 = \eta$ and for $i = 2, 3, u_i$ is an equation for U_i and uniquely determined by

$$s^{-a_i'} f_i(\xi s^{a_2'}, \zeta s^{a_3'}) = u_i(s^{-a_1'}, \xi, \zeta),$$

where f_i is an equation for $C_i \subset W_1$.

Moreover,

$$B = \mathbb{C}[u_1, u_2, u_3^*] = \mathbb{C}[u_1, u_2^*, u_3],$$

with u_i and u_i^* homogeneous of weight a_i' and if

$$u_2 = G_2(u_1, u_2^*, u_3)$$
 and $u_3 = G_3(u_1, u_2, u_3^*),$

then the equations

$$z_2^{\alpha_2} = G_2(z_1^{\alpha_1}, z_2^*, z_2^{\alpha_3})$$
 and $z_3^{\alpha_3} = G_3(z_1^{\alpha_1}, z_2^{\alpha_2}, z_3^*)$

describe X (in two ways) as a hypersurface in \mathbb{C}^4 .

- 3.1.1. Remark. 1) (3)(ii) imposes a rather mild restriction that can be made quite explicit ([KR3], 1.11.1).
- 2) Possibilities for f_2 , f_3 , and hence for G_2 , G_3 , can be worked out explicitly with the help of the *epimorphism theorem* of Abhyankar, Moh and Suzuki [AM], [S].

The key to 3.1 is the following observation.

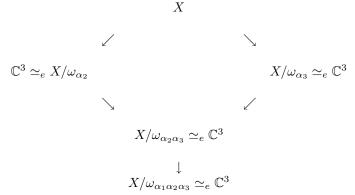

3.2. Proposition ([KR3], 2.6, 2.7). Suppose X is as in 3.1 and $\alpha_2 = 1$, $\alpha_3 > 1$. Then

$$X/\omega_{\alpha_3} \simeq_e \mathbb{C}^3 \text{ implies } X \simeq_e \mathbb{C}^3.$$

A similar result holds if $\alpha_2 > 1$, $\alpha_3 = 1$. Also,

$$X/\omega_{\alpha_1} \simeq_e \mathbb{C}^3 \text{ implies } X \simeq_e \mathbb{C}^3.$$

In view of 1.4 we obtain a commutative diagram

- 3.1 is an elaboration of the possibilities for such a diagram. It is not difficult to decide when X is equivariantly isomorphic to \mathbb{C}^3 (see 3.4). The question of just isomorphism with \mathbb{C}^3 , on the other hand, proved to be much more elusive.
- 3.3. Let us for instance choose $a=b=c=1, \ \alpha_2=2$ and $\alpha_3=3$ and a parabola and straight line for C_2 and C_3 . Then in suitable coordinates X is defined in \mathbb{C}^4 by

$$x + x^2y + z^2 + t^3 = 0.$$

X is dominated birationally by \mathbb{C}^3 and there exists a surjective quasi-finite map $\mathbb{C}^3 \to X$ ([KR3], 7.7 and 7.8). It is shown in [M-L1] that, nevertheless, X is not isomorphic to \mathbb{C}^3 . The proof is based implicitly on the computation of the following invariant:

$$AK(X) = \bigcap_{\partial \in LND(X)} \operatorname{Ker} \partial$$

where LND(X) is the set of locally nilpotent derivations on the ring $\mathbb{C}[X]$ of regular functions on X. For this hypersurface $AK(X) \neq \mathbb{C}$, but clearly $AK(\mathbb{C}^3) = \mathbb{C}$.

Let X be as in 3.1. We define

$$\varepsilon = (r-1)(\alpha_2 - 1)(\alpha_3 - 1)$$

($\varepsilon = \text{rank } \pi_2(X - X^+)$ is an invariant of the higher-dimensional knot (X, X^+) ([KR3], 4.8)).

3.4. Theorem ([KR3], remark following 5.1). Let X be as in 3.1. Then $X \simeq_e \mathbb{C}^3$ if and only if $\varepsilon = 0$.

3.5. Theorem ([KM-L]). Let X be as in 3.1. If $\varepsilon > 0$, then $X \not\simeq \mathbb{C}^3$.

If now X is \mathbb{C}^3 with a hyperbolic \mathbb{C}^* -action, then by 2.1 it is one of the X in 3.1 and hence $X \simeq_e \mathbb{C}^3$ by 3.4 and 3.5.

4. The computation of AK(X)

4.1. Theorem 3.5 is again the consequence of the fact that $AK(X) \neq \mathbb{C}$ [KM-L]. More precisely, $AK(X) = \mathbb{C}[X]$ unless X is isomorphic to a hypersurface in \mathbb{C}^4 given by one of the following equations:

(i)
$$x + x^k y + z^{\alpha_2} + t^{\alpha_3} = 0$$
 or

(ii)
$$x + y(x^k + z^{\alpha_2})^l + t^{\alpha_3} = 0$$

where $k \geq 2, l \geq 1$, and in the second equation $(kl, \alpha_3) = 1$. In case (i) AK(X) is the restriction of $\mathbb{C}[x]$ to X and in case (ii) AK(X) is the restriction of $\mathbb{C}[x, z]$ to X.

4.2. The scheme of the computation of AK(X) is discussed below. Every X from 3.1 is the hypersurface P(x, y, z, t) = 0 where

$$(x, y, z, t) = (z_3^*, z_1, z_2, z_3)$$
 and $P(x, y, z, t) = t^{\alpha_3} - G_3(y^{\alpha_1}, z^{\alpha_2}, x)$.

The polynomials from 4.1 (i) and (ii) are examples of such P. A derivation ∂ on $\mathbb{C}[X]$ is said to be of *Jacobian type* if $\partial(f)$ coincides with the restriction of $J_{x,y,z,t}(P,\varphi_1,\varphi_2,\varphi)$ to X where $\varphi_1,\varphi_2 \in \mathbb{C}[x,y,z,t]$ are fixed and the restriction of $\varphi \in \mathbb{C}[x,y,z,t]$ to X coincides with $f \in \mathbb{C}[X]$.

4.3. Proposition ([KM-L]). Let $\delta \in LND(X)$ be nontrivial and let φ_1, φ_2 be such that $\varphi_1|_X, \varphi_2|_X \in \text{Ker } \delta$ and P, φ_1, φ_2 are algebraically independent. Then ∂ has the same kernel as δ .

Furthermore, since the transcendence degree of the field of fractions of Ker δ is 2 [M-L1], one can always find φ_1, φ_2 , and therefore ∂ as above.

4.4. We consider degree functions L on $\mathbb{C}[x,y,z,t]$ obtained by assigning real weights to the variables. The L-quasi-leading part φ^L of a nonzero polynomial φ is the sum of the terms from φ whose L-degree coincides with $L(\varphi)$. Suppose, given φ_1 , there exists a degree function L_1 with positive values such that for any other degree function L_2 with positive values each nonzero monomial from φ^{L_2} is also present in φ^{L_1} . We then call

$$\hat{\varphi} := \varphi^{L_1}$$

the quasi-leading part of φ . In cases 4.1 (i) and (ii) \hat{P} coincides with $x^ky+z^{\alpha_2}+t^{\alpha_3}$ and $y(x^k+z^{\alpha_2})^l+t^{\alpha_3}$ respectively. In all other cases \hat{P} also exists and can be computed explicitly by virtue of the Abhyankar-Moh-Suzuki theorem (see 3.1.1 (ii)). Consider further only those degree functions (may be with negative values) which satisfy the condition

$$P^L = \hat{P}$$

4.5. Proposition ([KM-L]). Let ∂ be a nontrivial locally nilpotent derivation of Jacobian type on $\mathbb{C}[X]$. Then polynomials φ_1, φ_2 can be chosen so that $\varphi_1|_X, \varphi_2|_X \in \text{Ker } \partial$ and $\hat{P}, \varphi_1^L, \varphi_2^L$ are algebraically independent.

- 4.6. With ∂ as in 4.5, suppose that \hat{X} is the hypersurface $\hat{P}(x,y,z,t) = 0$ in \mathbb{C}^4 and that ∂^L is the derivation on $\mathbb{C}[\hat{X}]$ such that $\partial^L(f)$ coincides with restriction of $J_{x,y,z,t}(\hat{P},\varphi_1^L,\varphi_2^L,\varphi)$ to \hat{X} , where the restriction of $\varphi \in \mathbb{C}[x,y,z,t]$ to \hat{X} coincides with $f \in \mathbb{C}[\hat{X}]$. Then ∂^L is nontrivial and also locally nilpotent [M-L1].
- 4.7. Since \hat{P} is known explicitly, we can find all nontrivial locally nilpotent derivations of Jacobian type on $\mathbb{C}[\hat{X}]$. If P is not as in 4.1 (i) or (ii) there are no such derivations. By 4.3 and 4.6 there is no nontrivial locally nilpotent derivation on $\mathbb{C}[X]$, that is, $AK(X) = \mathbb{C}[X]$.
- 4.8. In case 4.1 (ii) the kernel of any nontrivial locally nilpotent derivation ∂^L on $\mathbb{C}[\hat{X}]$ is contained in $\mathbb{C}[x,z]|_{\hat{X}}$. Since this is true for every L satisfying condition 4.4, it follows ([KM-L], Theorem 8.4) that the kernel of the corresponding nontrivial locally nilpotent derivation ∂ on $\mathbb{C}[X]$ is contained in $\mathbb{C}[x,z]|_X$. The transcendence degree of the field of fractions of $\ker \partial$ is 2 and $\ker \partial$ is algebraically closed in $\mathbb{C}[X]$ [M-L1]. Hence $\ker \partial = \mathbb{C}[x,z]$. In case 4.1 (ii) nontrivial locally nilpotent derivations on $\mathbb{C}[X]$ exist, for instance $J_{x,y,z,t}(P,x,z,\varphi)|_X$. This yields $AK(X) = \mathbb{C}[x,z]|_X$.
- 4.9. In case 4.1 (i) nontrivial locally nilpotent derivations on $\mathbb{C}[X]$ exist as well. Examples are $J_{x,y,z,t}(P,x,z,\varphi)|_X$ and $J_{x,y,z,t}(P,x,t,\varphi)|_X$. The intersection of the kernels of these locally nilpotent derivations is $\mathbb{C}[x]|_X$, whence it suffices to show that $x \in \operatorname{Ker} \partial$ for every nontrivial $\partial \in LND(X)$. It can be shown that $\operatorname{Ker} \partial^L \subset \mathbb{C}[x,z,t]|_{\hat{X}}$ [KM-L]. Varying L under the condition 4.4 we prove that $\operatorname{Ker} \partial \subset \mathbb{C}[x,z,t]|_X$. From this we deduce that $\partial(\mathbb{C}[x,z,t]|_X) \subset x^k\mathbb{C}[x,z,t]|_X$ with k as in 4.1. Since $\mathbb{C}[x,z,t]|_X \not\subset \operatorname{Ker} \partial$, there exists $f \in \operatorname{Ker} \partial \setminus 0$ which is divisible by x, and then $x \in \operatorname{Ker} \partial$ by [FLN], that is, $AK(X) = \mathbb{C}[x]$.

5. Further results

Once 2.5 and 2.2 are established, the fact that S' = X//T can be forgotten in the proof of 2.4. In special cases, a geometric characterization of \mathbb{C}^2/ω_a is obtained.

5.1. Theorem ([KR4], 10.1). Suppose S' is as in 2.2. If either q is an ordinary a-fold point, that is $b \equiv c \mod a$, or the minimal resolution of q is a single (-a)-curve, or q is a rational double point, that is, $b \equiv -c \mod a$, or the minimal resolution of q is a chain of a - 1 (-2)-curves, then

$$S' \simeq \mathbb{C}^2/\omega_a$$
.

We do not know whether the restriction on the analytic type of q is needed in 5.1.

Extending the arguments of [KP], Popov [P] recently proved that any effective action of a noncommutative, connected reductive group on \mathbb{C}^3 is linearizable. Since effective actions of $(\mathbb{C}^*)^r$, r > 1, are linearizable by [B-B], we obtain

5.2. Theorem. Any action of a connected, reductive group G on \mathbb{C}^3 is linearizable.

It is an open question whether the connectedness assumption in 5.2 can be removed, and in particular, whether finite group actions on \mathbb{C}^3 are linearizable.

It is reasonable to expect that our methods and results will shed some light in general on codimension 2 torus actions on \mathbb{C}^n . As an illustration, consider the possibility that $X \times \mathbb{C} \simeq \mathbb{C}^4$, where X is a \mathbb{C}^* -threefold. For linearizability of the

obvious $(\mathbb{C}^*)^2$ -action the following weak cancellation conjecture is required: Let X be an affine threefold such that $X \times \mathbb{C} \simeq \mathbb{C}^4$. Then $X \simeq \mathbb{C}^3$ or X does not admit an effective \mathbb{C}^* -action.

This is known for nonhyperbolic actions. For hyperbolic actions, one would have to show that $X \times \mathbb{C} \not\simeq \mathbb{C}^4$ for the threefolds in 3.1. This is true in the case when X is not isomorphic to a hypersurface of the form 4.1 (i) or (ii) since $AK(Y \times \mathbb{C}) = \mathbb{C}[Y]$ for every algebraic manifold Y with $AK(Y) = \mathbb{C}[Y]$ [M-L2].

We remark that linearizability of \mathbb{G}_m -actions on \mathbb{A}^3 in positive characteristic is an open question, even in certain nonhyperbolic cases.
