

## NOTE ON $\Gamma^*$ -SEMIGROUPS

BY TAKAYUKI TAMURA

Communicated by Edwin Hewitt, February 20, 1962

The system  $L(S)$  of all nonvoid subsemigroups of a semigroup  $S$  is generally a semilattice<sup>1</sup> with respect to the inclusion relation.  $L(S)$  is called the subsemigroup semilattice of  $S$ . In the previous paper [1] we determined all the  $\Gamma$ -semigroups,<sup>2</sup> i.e., the semigroups whose subsemigroup semilattices are chains. In detail, all the types of  $\Gamma$ -semigroups are

- (1.1) cyclic groups  $G(p^n)$  of order of prime power,
- (1.2) quasi-cyclic groups  $G(p^\infty)$ ,
- (1.3) unipotent semigroups generated by  $d$  with each of the following defining relations:

$$(1.3.1) \quad d^2 = d^3,$$

$$(1.3.2) \quad d^3 = d^4,$$

$$(1.3.3) \quad d^2 = d^{p^m+2}, \quad p \text{ prime},$$

$$(1.3.4) \quad d^3 = d^{p^m+3}, \quad p \text{ prime} \neq 2.$$

In the present note, we shall define  $\Gamma^*$ -semigroups as generalizations of  $\Gamma$ -semigroups and shall report the structure of  $\Gamma^*$ -semigroups except for a part of infinite  $\Gamma^*$ -groups. The proof will be omitted here but will be given elsewhere.<sup>3</sup>

DEFINITION. A semigroup  $S$  is called a  $\Gamma^*$ -semigroup if every subsemigroup different from  $S$  is a  $\Gamma$ -semigroup.

$S$  is a  $\Gamma^*$ -semigroup if and only if  $L(S)$  is a semilattice satisfying:

Any subset which contains the greatest element is a subsemilattice. A semilattice of this kind is called a  $C_0$ -semilattice. Obviously all the semigroups of order 2 are  $\Gamma^*$ -semigroups, and a homomorphic image of a  $\Gamma^*$ -semigroup is also a  $\Gamma^*$ -semigroup.

LEMMA 1. *Every element of a  $\Gamma^*$ -semigroup is of finite order, that is, for any element  $x$  there is an idempotent  $e$  and a positive integer  $n$  such that  $x^n = e$ .*

LEMMA 2. *A  $\Gamma^*$ -semigroup of order  $> 2$  is unipotent. (i.e., an idempotent element is unique).*

Generally a unipotent semigroup any element of which is of finite

---

<sup>1</sup> By a semilattice we mean a partially ordered set in which there is a join of two elements.

<sup>2</sup> In [1] we called them  $\Gamma$ -monoids.

<sup>3</sup> *Semigroups and their subsemigroups semilattices*, to appear.

order is determined by a group and a  $Z$ -semigroup (i.e., a unipotent semigroup with zero) [2; 3]. By Lemmas 1 and 2, we can make the discussion proceed to  $\Gamma^*$ - $Z$ -semigroups,  $\Gamma^*$ -groups, and then to the general cases.

**THEOREM 1.** *Any  $\Gamma^*$ - $Z$ -semigroup is of order  $\leq 4$ . All the types of  $\Gamma^*$ - $Z$ -semigroups other than  $\Gamma$ -semigroups are listed as follows:*

- (2.1)  $\{0, a, b\}$  of order 3 where  $xy=0$  for all  $x, y$ ,
- (2.2)  $\{0, a, b, c\}$  of order 4 defined as
  - (2.2.1)  $b^2=c^2=a$  and other products  $=0$ .
  - (2.2.2)  $b^2=cb=c^2=a$  and other products  $=0$ .
  - (2.2.3)  $b^2=c^2=bc=cb=a$ , and other products  $=0$ .

As far as the  $\Gamma^*$ -groups are concerned, we shall limit ourselves to the case of  $\Gamma^*$ -groups which are properly homomorphic to  $\Gamma$ -groups.

We can prove that any  $\Gamma^*$ -group which is properly homomorphic to a  $\Gamma$ -group has a normal subgroup of index of a prime number. Making use of the theory of finite groups [4; 5; 6], we have

**THEOREM 2.** *Any  $\Gamma^*$ -group, which is not a  $\Gamma$ -group and is homomorphic to a  $\Gamma$ -group of order  $> 1$ , has one of the following types.*

- (3.1) *The groups of order  $pq$  where  $p$  and  $q$  are different primes. There are two types (3.1).*
- (3.2) *The elementary abelian group:  $G(p) \times G(p)$ .*
- (3.3) *The generalized quaternion group of order 8.*

Incidentally a finite  $\Gamma^*$ -group, which is not a  $\Gamma$ -group, is homomorphic to a  $\Gamma$ -group; a commutative  $\Gamma^*$ -group which is not a  $\Gamma$ -group is the direct product of two groups of prime order. Consequently we see that the result of Theorem 2 includes the cases where a  $\Gamma^*$ -group is homomorphic to a nontrivial finite group or a commutative group. However the problem of determination of the remaining case is still open.

Next, let  $S$  be a unipotent  $\Gamma^*$ -semigroup which is neither a group nor a  $Z$ -semigroup. Then we can prove that  $S$  must be finite. The kernel (i.e., the least ideal) of  $S$  is of type  $G(p^n)$ , and the difference semigroup  $D$  of  $S$  modulo  $G(p^n)$ , due to Rees [7] is a  $Z$ -semigroup which has one of the types (1.3.1), (2.1), (2.2.1), (2.2.2), (2.2.3).

Let  $e$  be the unique idempotent of  $S$ , and let  $d$  be a generator of  $D$ .  $G(p^{n-1})$  will denote the subgroup of order  $p^{n-1}$  of  $G(p^n)$ .

**THEOREM 3.** *When  $G(p^n)$  is given, we can determine all the unipotent  $\Gamma^*$ -semigroups, non  $\Gamma$ -semigroups, whose kernel is  $G(p^n)$ , by the product of  $e$  and  $d$  in the following way.*

(4.1) In the case  $D$  of order 2,  $S = G(p^n) \cup \{d\}$ ,  $n \neq 0$ ,

$$ed \in G(p^{n-1}) - G(p^{n-2}).^4$$

(4.2) In the case  $D$  of order 3,  $D$  is of type (2.1) and  $S = G(p^n) \cup \{d_1, d_2\}$ ,  $n \neq 0$ .

(4.2.1)  $ed_1 = ed_2 \in G(p^n) - G(p^{n-1})$ ,

(4.2.2)  $p^n \neq 2$ ,  $ed_1 \neq ed_2$ ;  $ed_1, ed_2 \in G(p^n) - G(p^{n-1})$ .

(4.3) In the case  $D$  of order 4,  $S = G(p^n) \cup \{d_1, d_2, d_3\}$ ,  $d_2^2 = d_3^2 = d_1$ ,  $n \neq 0$ ,  $p \neq 2$ .

- (4.3.1)  $D$  of (2.2.1)
  - (4.3.2)  $D$  of (2.2.2)
  - (4.3.3)  $D$  of (2.2.3)
- $$\left. \begin{array}{l} \\ \\ \end{array} \right\} ed_2 = ed_3 \in G(p^n) - G(p^{n-1}).$$

According to the above-mentioned theorems, we see that if  $S$  is a finite  $\Gamma^*$ -semigroup, the finite  $C_0$ -semilattice  $L(S)$  satisfies Jordan-Dedekind condition (or  $J$ -condition cf. [8]). Generally a finite  $C_0$ -semilattice  $K$  satisfying  $J$ -condition is called a  $C_0J$ -semilattice. Let  $\delta$  denote the dimension of  $K$  (cf. [8]),  $\lambda$  the breadth, i.e., the number of the maximal chains in  $K$ , and  $\mu$  the order, i.e., the number of elements of  $K$ .

$\Gamma$ -Semigroups                      Idempotent Semi-groups of order 2                      (2.1), (3.1)                      (2.2)

**THEOREM 4.** A finite  $C_0J$ -semilattice  $K$  is isomorphic to certain  $L(S)$  for some finite  $\Gamma^*$ -semigroup  $S$  if and only if  $\delta$ ,  $\lambda$ , and  $\mu$  satisfy the following conditions.

- (5.1)  $\delta + \lambda - \mu = 0$ ,
- (5.2)  $\lambda = \alpha + 1$  where  $\alpha = 0$  or 1 or any prime number,

<sup>4</sup>  $A - B$  denotes the set of elements of  $A$  which are not in  $B$ .

(3.1), (3.2)

(3.3)

(4.1), (4.2), (4.3)

- (5.3)  $\begin{cases} \text{if } \lambda = 1 \text{ or } 2, \text{ then } \delta \text{ can be taken as an arbitrary positive integer,} \\ \text{if } \lambda = 3, \text{ then } \delta = 2 \text{ or } 3, \\ \text{if } \lambda = p+1, p \text{ being a prime number } > 2, \text{ then } \delta = 2. \end{cases}$

Finally we shall show the diagrams of  $L(S)$  for a finite  $\Gamma^*$ -semi-group  $S$ .
