

**SOLVABILITY OF THE FIRST COUSIN PROBLEM AND
VANISHING OF HIGHER COHOMOLOGY GROUPS
FOR DOMAINS WHICH ARE NOT DOMAINS
OF HOLOMORPHY. II**

BY AVNER FRIEDMAN¹

Communicated by F. Browder, September 8, 1965

This work is a continuation of [2]. In [2] we studied the cohomology groups $H^q(X \setminus A, \mathcal{O})$ where $A(\subset X)$ is a closed generalized polydisc. Here we consider the general case where A is the closure of a domain of holomorphy. This general case was treated in [1] for $q=1$, but the present method (for $q \geq 1$) is entirely different.

We adopt the definition in [4] of analytic polyhedron. By an analytic polyhedron in *general position* we mean an analytic polyhedron as defined in [3, p. 288].

THEOREM 1. *Let $A \subset \mathbb{C}^n$ be the closure of a bounded analytic polyhedron in general position and let X be any open set in \mathbb{C}^n , containing A . Then the restriction map*

$$(1) \quad H^q(X, \mathcal{O}) \rightarrow H^q(X \setminus A, \mathcal{O}) \quad (1 \leq q \leq n - 2)$$

is bijective.

We proceed as in [2] except that now we take $G = B \setminus A$ where $B = \{z \in D; f_j(z) \in \Delta'_j \text{ for } j=1, \dots, N\}$ where A is defined by $A = \{z \in D; f_j(z) \in \Delta_j \text{ for } j=1, \dots, N\}$ where f_j are holomorphic in D , Δ'_j is some open neighborhood of $\bar{\Delta}_j$, and $\bar{B} \subset D$. (The argument in [2] can be simplified by dropping out the sets U_{i_1}, \dots, U_{i_q} which occur in the covering $X \setminus A$.) All we need to prove is the following lemma.

LEMMA. $H^p(G, \mathcal{O}) = 0$ for $1 \leq p \leq n - 2$.

PROOF. For simplicity we take Δ_j to be the unit disc and Δ'_j to be a disc with radius $1 + \epsilon$, homothetic to Δ_j . Clearly $G = \bigcup_{i=1}^N U_i$ where U_i is defined as B except for the additional condition $|f_i(z)| > 1$. Thus, each U_i is also an analytic polyhedron. We next proceed analogously to [6, p. 349] and represent $f_{i_0 \dots i_p}$ in $U = \bigcap_{i=1}^N U_i$ as $\sum C_M(f_{i_0 \dots i_p})$ where $M = \{M', M''\}$ is a set of indices j_1, \dots, j_n such that the integration in $C_M(f)$ is taken over $|f_{j_1}| = \gamma_1, \dots, |f_{j_n}| = \gamma_n$ where $\gamma_h = 1$ if $j_h \in M''$ and $\gamma_h = 1 + \epsilon$ if $j_h \in M'$; the above integral representation is that given by the Cauchy-Weil formula [3],

[7]. Actually we should have used the representation in compact subsets of U , but since this does not affect all the arguments below, we simplify the notation by representing $f_{i_0 \dots i_p}$ in U .

One verifies that (α) if $i \in M'', i \notin \{i_0, \dots, i_p\}$ then $C_M(f_{i_0 \dots i_p}) = 0$. Indeed this follows by the Cauchy-Poincaré theorem [3, p. 264] applied in the $(n+1)$ -dimensional set defined by $|f_j| = 1 + \epsilon$ for $j \in M'$, $|f_j| = 1$ for $j \in M'' \setminus \{i\}$, and $|f_i| \leq 1$. Since $p+1 < n$, it follows from (α) that $(\beta) C_M(f_{i_0 \dots i_p}) = 0$ if $M'' = \{1, 2, \dots, n\}$. Next, $(\gamma) C_M(f_{i_0 \dots i_p})$ is holomorphic in $U_{i_0 \dots i_p} = \bigcap_{j=0}^p U_{i_j}$, since, by (α) , we may assume that $M'' \subset \{i_0, \dots, i_p\}$. Finally, (δ) if $i \notin M''$ then $C_M(f_{i_0 \dots i_{p-1}})$ is holomorphic in $U_{i_0 \dots i_{p-1}}$. To construct g with $\delta g = f$ (f any given p -cocycle) it suffices to construct, for each fixed M , g with $\delta g = C_M(f)$. We may assume that there is an $i \notin M'', 1 \leq i \leq n$, since otherwise $C_M(f) = 0$ by (β) . We then take $g_{i_0 \dots i_{p-1}} = C_M(f_{i_0 \dots i_{p-1}})$.

COROLLARY 1. *If $N = n$ in Theorem 1 then there is a surjective map (1) also for $q = n$. If, further, X is a domain of holomorphy, then $H^{n-1}(X \setminus A, \Theta) \neq 0$.*

The first part follows by observing that $H^n(G, \Theta) = 0$ and using the Mayer-Vietoris sequence (see [0, p. 236]) for $B, X \setminus A$. If the second part is false then $H^q(X \setminus A, \Theta) = 0$ for $1 \leq q \leq n$. Employing Dolbeault's theorem and [5, Theorem 4.2.9] it follows that $X \setminus A$ is a domain of holomorphy.

THEOREM 2. *Let $A = \bigcap_{j=1}^\infty X_j$ where $X_{j-1} \supset \bar{X}_j, X_j$ is a bounded domain of holomorphy in \mathbb{C}^n and A is a closed set, and let X be any open set in \mathbb{C}^n , containing A . Then the restriction map (1) is bijective for $1 \leq q \leq n-2$ and injective for $q = n$.*

PROOF. Each X_j can be exhausted by a sequence of analytic polyhedra with $N = n$ (see [4, p. 218]), and by slightly modifying the domains in which the values of the functions (defining the analytic polyhedron) lie, we get a sequence of analytic polyhedra in general position. Thus we can write $A = \bigcap_{j=1}^\infty P_j$ where P_j are analytic polyhedra in general position, and $P_{j-1} \supset \bar{P}_j$. Take a covering W of $X \setminus A$ by domains of holomorphy such that for each $j = 1, 2, \dots$, there is a subset of W which is a covering of $X \setminus \bar{P}_j$ and such that the closure of each set in W does not intersect ∂A . Using Leray's lemma [4] and the fact that the restriction maps

$$(2) \quad H^r(X, \Theta) \rightarrow H^r(X \setminus \bar{P}_j, \Theta) \quad (r = q, q - 1)$$

are bijective (for any $1 \leq q \leq n-2$) it follows by the isomorphisms $H^r(X \setminus \bar{P}_j, \Theta) \rightarrow (H^r(X \setminus P_{j-1}, \Theta))$ and [0, p. 241 and p. 250] that the map (1) is bijective we actually need only the injectivity of (2) for $r = q$ and the surjectivity of (2) for $r = q, q - 1$.

EXAMPLE. If A is a compact convex set, or if ∂A is C^2 and strictly pseudoconvex, then A satisfies the assumptions in Theorem 2. If, in particular, X is a domain of holomorphy, then $H^q(X \setminus A, \Theta) = 0$ for $1 \leq q \leq n-2$.

Added in proof. Theorems 1, 2 remain true if Θ is replaced by any coherent analytic sheaf \mathcal{F} over x , free in a neighborhood of A . Assume now that \mathcal{F} has a free resolution of length d in a neighborhood of ∂A . Then the lemma holds for $1 \leq p \leq n-2-d$. Using a covering of $x \setminus A$ as in [2] and, additionally, a domain of holomorphy U_* containing A but not intersecting the U_j for $j = i_0, \dots, i_q$, we get:

THEOREM 3. *If A, X are as in Theorem 2 and if \mathcal{F} is as above, then the restriction map (1), with Θ replaced by \mathcal{F} , is bijective for $2 \leq q \leq n-2-d$.*

This theorem yields the following result on cohomology with compact support: $H_0^q(\Omega, \mathcal{F}) = 0$ for $2 \leq q \leq n-1-d$, if Ω is a domain of holomorphy in C^n . (Overlapping results were proved, by a different method, in [0], using Serre's duality theorem.)

PROOF FOR $\mathcal{F} = \Theta$: Given a $\bar{\partial}$ -closed q -form f , with compact support in Ω , solve $\bar{\partial}g = f$ in C^n ; then solve $\bar{\partial}v = g$ outside some compact analytic polyhedron in Ω (using Theorem 3). $u = v - \bar{\partial}(\zeta v)$, for some $\zeta \in C_0^\infty$ satisfies $\bar{\partial}u = f$ and has compact support in Ω . For general \mathcal{F} we work with q -cochains and coboundary operators. The above proof, together with $H_0^n(\Omega, \Theta) \neq 0$, leads to:

COROLLARY. *If Ω is a domain of holomorphy and a star domain, and if B is any open set with $\Omega \subset \subset B \subset \subset G$, then $H^{n-1}(B \setminus \bar{\Omega}, \Theta) \neq 0$.*
