

# THE IMPOSSIBILITY OF FILLING $E^n$ WITH ARCS

BY STEPHEN L. JONES<sup>1</sup>

Communicated by R. H. Bing, August 17, 1967

The purpose of this paper is to outline a proof of the following

**MAIN THEOREM.** *If  $f$  is a closed continuous map of  $E^n$  onto any space  $S$ , then some point in  $S$  has an inverse image which is not an arc.*

In 1936 J. H. Roberts [1] showed that there does not exist an upper semicontinuous (usc) collection of arcs filling the plane. Recently L. B. Treybig [2] has obtained some partial results for polygonal arcs in  $E^n$ . In 1955 Eldon Dyer [3] outlined a proof that there is no continuous decomposition of  $E^n$  into arcs. This proof incorporates some of the ideas of both Roberts and Dyer.

We will suppose that all statements are for  $E^n$  for a given  $n$ .

**DEFINITIONS.** If  $U$  and  $V$  are sets with disjoint closures, we say that an arc  $\alpha$  has  $k$  folds between  $U$  and  $V$  if  $\alpha$  contains  $k+1$  disjoint subarcs between  $U$  and  $V$ . Furthermore, if the distance between each pair of the  $k+1$  subarcs is greater than  $\epsilon$ , we say that the *width* of the folds is greater than  $\epsilon$ . If  $\alpha$  contains a subarc which has endpoints in  $U$  and which intersects  $V$ , then  $\alpha$  is said to have a fold with the *bend* in  $V$ .

If  $K$  is a set,  $\epsilon > 0$ , let  $N_\epsilon(K)$  denote the open  $\epsilon$ -neighborhood of  $K$  in  $E^n$ . If  $H$  is a collection of sets, let  $H^*$  denote the set of all points covered by elements of  $H$ .

Suppose  $A$  is compact and  $B$  is a closed subset of  $A$ . If any two points of  $E^n - A$  which are separated by  $A$  are also separated by  $B$ , then  $B$  is said to be *essential* in  $A$ . If  $H$  is a usc collection of arcs and points filling  $A$  and  $B$  intersects each element of  $H$ , then  $B$  is said to be *full* in  $A^H$ . If  $B$  meets each element of  $H$  in a continuum, then  $B$  is said to be a *quasi-section* of  $A^H$ .

Assume  $H$  is a usc collection of arcs and points filling the compact set  $X$ .

**LEMMA 1.** *If  $Y$  is a quasi-section of  $X^H$  then  $Y$  is essential in  $X$ .*

The proof is an exercise in the Vietoris mapping theorem on the Čech homologies of  $X$ ,  $Y$ , and the decomposition space.

**LEMMA 2.** *If  $K$  is full in  $X^H$ ,  $U$  is open,  $\bar{U} \cap K = \emptyset$ , and no element*

<sup>1</sup> The results presented in this paper are a part of the author's Ph.D. thesis at the University of Wisconsin, written under the direction of Professor R. H. Bing.

of  $H$  has a fold between  $K$  and  $U$  with bend in  $U$ , then  $X$  has an essential subset that misses  $U$ .

It follows from the hypothesis that for each  $h \in H$ ,  $h - (h \cap U)$  contains a unique component which intersects  $K$ . If  $Y$  is the union of all such components,  $Y$  is a quasi-section of  $X^H$  and hence  $Y$  is an essential subset that misses  $U$ .

REMARK. Obviously, under the above conditions if  $U$  is connected,  $U$  cannot intersect two distinct components of  $E^n - X$ .

Suppose  $G$  is a usc collection of arcs and points filling some complete metric space. The collection  $G$  is said to be *continuous* at an element  $g$  if for every finite chain  $\mathcal{K}$  of open sets covering  $g$ , there exists an  $\epsilon > 0$  such that each element of  $G$  contained in  $N_\epsilon(g)$  intersects each element of  $\mathcal{K}$ . The collection  $G$  is said to be *equicontinuous* at  $g$  if  $G$  is continuous at  $g$  and no element of  $G$  contained in  $N_\epsilon(g)$  contains a fold between two nonadjacent links of  $\mathcal{K}$ . Roberts proved that the set  $G_1$  of elements at which  $G$  is continuous is dense in  $G$ , and the set  $G_2$  of elements at which  $G_1$  is equicontinuous is dense in  $G_1$ .

Suppose  $X$  is compact and  $H$  is a usc collection of arcs and points filling  $X$ .

LEMMA 3. *If  $K$  is full in  $X^H$ ,  $Q$  is a quasi-section of  $X^H$  that contains an endpoint of each element of  $H$ , and  $K \cap Q = \emptyset$ , then there is a quasi-section  $Y$  of  $X^H$  such that  $Q$  is not contained in  $Y$ .*

Let  $h_2$  denote an element of  $H_2$ . We can find an  $\epsilon > 0$  such that  $h_2$  contains no folds between  $N_{2\epsilon}(K)$  and  $N_\epsilon(Q)$ . Since  $H_1$  is equicontinuous at  $h_2$ , if  $h_1 \in H_1$  is near  $h_2$ , then  $h_1$  contains no folds between  $N_{2\epsilon}(K)$  and  $N_\epsilon(Q)$ . Suppose  $h \in H$ ,  $h$  is very near  $h_2$ , and the component of  $h - [h \cap N_\epsilon(K)]$  that meets  $Q$  contains a fold between  $N_{2\epsilon}(K)$  and  $N_\epsilon(Q)$ . This implies that every element of  $H_1$  very near  $h$  must also contain such a fold, since every such element must span between  $K$  and  $Q$ , and to do this it must "follow"  $h$  from  $N_\epsilon(Q)$  to  $N_{2\epsilon}(K)$ , back to  $N_\epsilon(Q)$ , and again to  $N_{2\epsilon}(K)$  before it can intersect  $K$ . Hence from Lemma 2 we have a quasi-section  $Y_1$  of  $X^H$  of arcs from  $\text{Bd } N_\epsilon(K)$  to  $Q$ , and a quasi-section  $Y_2$  of  $Y_1$  which misses a very small open set about  $h_2 \cap Q$ . Trivially,  $Y_2$  is a quasi-section of  $X^H$ , and this completes the proof of Lemma 3.

We will suppose throughout the remainder of the paper that  $G$  is a usc collection of arcs filling  $E^n$ .

Suppose  $g$  is an element at which  $G$  is continuous,  $U$  and  $V$  are open sets with disjoint closures, and each of  $U$  and  $V$  contains an end-

point of  $g$ . Let  $K$  denote a closed neighborhood of the endpoint of  $g$  in  $U$ ,  $K \subset U$ . Let  $M$  denote the set of all elements of  $G$  which intersect  $\text{Bd } N_\epsilon(g)$ , for some small  $\epsilon$ . Hence  $M^*$  is compact and if  $\epsilon$  was selected small enough, then (a)  $M^* \cap K$  is full in  $M^{G|M}$ , and (b)  $V$  meets two components of  $E^n - M^*$ . The remark following Lemma 2 implies there is an arc with a fold between  $K \cap M$  and  $V$ , and hence

**THEOREM 1.** *There exists an element of  $G$  with a fold between  $U$  and  $V$  with the bend in  $V$ .*

To prove the Main Theorem, we need to find some arc with infinitely many folds between  $U$  and  $V$ . It should be noted that it is insufficient to obtain a sequence  $\{\alpha_i\}_{i>0}$  of elements of  $G$  such that each  $\alpha_j$  contains  $j$  folds between  $U$  and  $V$ , since the limit of such a sequence may be an arc with no folds at all. Thus we need sequences  $\{\alpha_i\}_{i>0}$  of arcs of  $G$  and  $\{d_i\}_{i>0}$  of positive numbers such that for each  $j$ , if  $k > j$ ,  $\alpha_k$  contains  $j$  folds between  $U$  and  $V$  of width at least  $d_j$ . The limit of such a sequence would be an arc with infinitely many folds between  $\bar{U}$  and  $\bar{V}$ . The following is an analogue to a lemma of Roberts.

**THEOREM 2.** *There exists an open set  $W$  such that each element of  $G$  that meets  $W$  contains a fold between  $\bar{U}$  and  $\bar{V}$ .*

**REMARK.** For  $\epsilon > 0$  the set of all elements having a fold between  $\bar{U}$  and  $\bar{V}$  of width  $\geq \epsilon$  is closed. Thus using Theorem 2 and the Baire category theorem we easily obtain an open set  $W'$  and a positive number  $d$  such that each element of  $G$  that meets  $W'$  contains a fold of width greater than  $d$ . The proof then proceeds similar to that of Roberts.

The proof of Theorem 2 is crucial and requires more machinery.

Note that since  $U$  and  $V$  were selected arbitrarily it is sufficient to show that for  $\epsilon > 0$ , there is an open set  $W$  such that each element that meets  $W$  contains a fold between  $N_\epsilon(U)$  and  $N_\epsilon(V)$ .

From Theorem 1 there is some arc  $\alpha$  of  $G$  which contains a fold between  $U$  and  $V$  with the bend in  $V$ . Let  $\alpha'$  denote a subarc of  $\alpha$  which has a fold between  $U$  and  $V$  with the bend in  $V$  but no subarc of  $\alpha'$  has this property. Hence  $\alpha'$  minus its endpoints separates  $\alpha$  into two components  $K_1$  and  $K_2$ . Let  $U_1$  and  $U_2$  denote small disjoint open sets about  $K_1$  and  $K_2$  respectively. Thus  $\alpha \cap U \subset U_1 \cup U_2$ , and every element of  $G$  near  $\alpha$  meets either  $U_1$  or  $U_2$  since every such element of  $G$  must intersect  $U$  (every element near  $\alpha$  is also near the element  $g$  at which  $G$  is continuous). Hence if  $\delta$  is small enough, every element of  $G$  contained in  $N_\delta(\alpha)$  which meets both  $U_1$  and  $U_2$  contains a fold

between  $N_\epsilon(U)$  and  $V$ . Thus the following lemma implies Theorem 2.

Suppose  $\alpha \in G$ ,  $U_1$  and  $U_2$  are open sets, each containing an end-point of  $\alpha$ ,  $\epsilon > 0$ , and every element of  $G$  near  $\alpha$  meets either  $U_1$  or  $U_2$ .

LEMMA 4. *There exists an open set  $W$  such that every element of  $G$  that meets  $W$  intersects both  $N_\epsilon(U_1)$  and  $N_\epsilon(U_2)$ .*

We assume this lemma to be false.

Let  $G'$  denote the usc collection of arcs and points filling  $E^n$  such that  $g' \in G'$  if and only if either (a) for some element  $g$  of  $G$ ,  $g'$  is a component of  $g - \{g \cap [N_{\epsilon/2}(U_1) \cup N_{\epsilon/2}(U_2)]\}$  or (b)  $g'$  is a point of  $N_{\epsilon/2}(U_1) \cup N_{\epsilon/2}(U_2)$ . Trivially, if Lemma 4 is false for  $G$  then it is false for  $G'$ .

Let  $L$  denote the set of all elements of  $G'$  which are near  $\alpha$  (here  $\alpha$  is considered as a point set, since  $\alpha \notin G'$ ) and which fail to intersect both  $N_\epsilon(U_1)$  and  $N_\epsilon(U_2)$ .  $L$  is naturally divided into  $L_1$ , those elements intersecting  $N_\epsilon(U_1)$  but not  $N_\epsilon(U_2)$ , and  $L_2$ , those elements intersecting  $N_\epsilon(U_2)$  but not  $N_\epsilon(U_1)$ .

Let  $M$  denote  $B^n - L^*$ , where  $B^n$  is a very large ball containing  $g$ ,  $\alpha$ ,  $L^*$ ,  $U$ ,  $V$ , etc.

LEMMA 4.1.  *$M$  separates  $U_1$  from  $U_2$ .*

This is obvious since  $L^* = L_1^* \cup L_2^*$ .

LEMMA 4.2.  *$L^*$  is dense near  $\alpha$ .*

This is a direct result from the assumption that Lemma 4 is false.

LEMMA 4.3. *No element of  $G'$  near  $\alpha$  contains a fold between  $N_\epsilon(U_1)$  and  $N_\epsilon(U_2)$ .*

Suppose  $\beta' \in G'$  near  $\alpha$  such that  $\beta'$  contains a fold between  $N_\epsilon(U_1)$  and  $N_\epsilon(U_2)$  with the bend in  $N_\epsilon(U_2)$ . Let  $\beta \in G$  such that  $\beta' \subset \beta$ . If  $W$  is a very small open set about a point in the bend of  $\beta$  in  $N_\epsilon(U_2)$ , then every element of  $G$  that meets  $W$  must "follow"  $\beta$  into  $N_\epsilon(U_1)$ , since recall that every element near  $\alpha$  must intersect either  $U_1$  or  $U_2$ . We are assuming such a  $W$  does not exist and hence this completes Lemma 4.3.

Let  $Q$  denote  $\overline{L_1^*} \cap \overline{L_2^*}$ .

LEMMA 4.4. *Every essential subset of  $M$  contains  $Q$ .*

Every subset of  $M$  that fails to contain every point of  $Q$  fails to separate  $L_1^*$  from  $L_2^*$  and hence fails to separate  $U_1$  from  $U_2$ .

LEMMA 4.5.  *$Q$  is a quasi-section of  $M^{G' \setminus M}$  near  $\alpha$ .*

If  $g' \in G'$ , and  $p$  is a point of  $g' \cap Q$ , then there is a subarc  $l_p$  of  $g'$  between  $\text{Bd } N_{\epsilon/2}(U_1)$  and  $\text{Bd } N_{\epsilon/2}(U_2)$  containing  $p$ . We observe that  $l_p$  is the union of a segment in  $\overline{L_1^*}$  and a segment in  $\overline{L_2^*}$ . Thus if  $q$  is another point of  $g' \cap Q$ , since  $g'$  contains no fold between  $N_\epsilon(U_1)$  and  $N_\epsilon(U_2)$ , then  $l_p = l_q$ , and hence  $p$  and  $q$  lie in the same component of  $g' \cap Q$ . Thus  $Q$  is a quasi-section of  $M^{G' \setminus M}$  near  $\alpha$ .

By a similar argument, if we let  $X$  denote  $\overline{L_1^*} \cap M$  near  $\alpha$ , then  $M' = [\text{Closure of } (M - \text{elements of } G' \text{ near } \alpha)] \cup X$  is a quasi-section of  $M^{G' \setminus M}$ . Hence  $M'$  is an essential subset of  $M$  and contains  $Q$  by Lemma 4.4. It follows from the definition of  $X$  that  $X$  is compact,  $G' \setminus X$  is a usc collection of arcs filling  $X$  such that  $\text{Bd } N_{\epsilon/2}(U_1)$  is full in  $X^{G' \setminus X}$ , and  $Q$  is a quasi-section of  $X$  which contains an endpoint of each arc in the decomposition. Lemma 3 implies there is a quasi-section  $Y$  of  $X$  which does not contain  $Q$ . However, if  $M'' = \text{cl } (M' - X) \cup Y$ ,  $M''$  is a quasi-section of  $M'$  and hence a quasi-section of  $M^{G' \setminus M}$ . Thus  $M''$  is an essential subset of  $M$  which does not contain  $Q$ . This contradicts Lemma 4.4 and completes the proof of Theorem 2.
