THE DIAMETER AND THE MEAN DISTANCE OF A RIEMANNIAN MANIFOLD

BOJAN MOHAR

Let $M$ be a compact Riemannian manifold. For $x, y \in M$, denote by $\rho(x, y)$ the distance between $x$ and $y$, i.e., the infimum of lengths of continuous piecewise $C^1$ paths between $x$ and $y$. (Notice that for geodesically complete manifolds there is always a path from $x$ to $y$ of length $\rho(x, y)$.)

The invariants of $M$ based on the distance $\rho$ are called metrical invariants. Most of them are related to the geometry of $M$. Let us mention a few of them.

The **diameter**, $\text{diam}(M)$, of $M$ is the maximal value of $\rho(x, y)$ for $x, y \in M$. If two points $x, y$ are at distance $\text{diam}(M)$, they are called antipodal.

Denote by $w = \int_M \rho(x, y) dV(y)$ the average distance of points in $M$ from $x$. Then

$$
(1) \quad \rho(x, M) = \frac{1}{\text{Vol}(M)} \int_M \rho(x, y) dV(y)
$$

the average distance of points in $M$ from $x$. Then

$$
(2) \quad \rho(M) = \frac{1}{\text{Vol}(M)} \int_M \rho(x, M) dV(x)
$$

is called the **mean distance** of $M$. These distances are important metric invariants of $M$, but, surprisingly enough, they have not been extensively investigated yet.

Denote by $\Delta$ the Laplace-Beltrami differential operator (Laplacian for short) on $M$. It is well known that the spectrum of $\Delta$ is a discrete set of real numbers, $\lambda_0 = 0 < \lambda_1 \leq \lambda_2 \leq \lambda_3 \leq \ldots$. The first nontrivial eigenvalue $\lambda_1(M)$ of the Laplacian is related to many geometric properties of $M$. In this note we present inequalities between the diameter, or the mean distance of $M$, and $\lambda_1(M)$. For $\delta > 0$, let $B(x, \delta)$ denote the ball of radius $\delta$ centered at $x \in M$, and let

$$
\nu(M, \delta) := \min_{x \in M} \text{Vol}(B(x, \delta)).
$$

**Theorem 1.** Let $M$ be a compact Riemannian manifold with the first nontrivial eigenvalue of the Laplace operator on $M$ equal to $\lambda_1$. Then for any $\delta > 0$,

$$
(3) \quad \text{diam}(M) \leq 2 \left( \delta + \frac{2}{\sqrt{\lambda_1}} \left[ \log_2 \frac{\text{Vol}(M)}{2\nu(M, \delta)} \right] \right).
$$

Theorem 2. Under the same assumptions as above and for arbitrary $x \in M$, 

$$\bar{p}(x, M) < \delta + \frac{2}{\sqrt{\lambda_1}} \left[ \log_2 \frac{\text{Vol}(M)}{\text{Vol}(\delta)} \right] + \frac{\delta \text{Vol}(M, \delta)}{\text{Vol}(M)}.$$  

Of course, (4) gives rise to the same upper bound on the mean distance $\bar{p}(M)$.

The main idea in the proofs of both theorems is the same. We sketch only the slightly simpler proof of Theorem 1. The details will appear elsewhere.

The main step in proving Theorem 1 is to show that large $\lambda_1$ forces fast growth of the manifold: By the Rayleigh's Theorem for the Laplacian $\Delta$ on $M$, 

$$\lambda_1 = \min \left\{ \frac{(\Delta f, f)}{(f, f)} \mid f \in C^2(M), \int_M f = 0, f \neq 0 \right\}$$

where $(f, g) = \int_M fg$. This implies a similar, handier formula 

$$\lambda_1 = 2 \text{Vol}(M) \min_{\Phi} \frac{(\Delta g, g)}{\int_M \int_M [g(x) - g(y)]^2 dV(x) dV(y)}$$

where $\Phi$ is the set of all nonconstant $C^2$ functions on $M$.

Let $N$ be a compact submanifold of $M$ of codimension one which divides $M$ into two disjoint open submanifolds $M_1, M_2$ with common boundary $N = \partial M_1 = \partial M_2$. For $\varepsilon > 0$, let $N_\varepsilon := \{ x \in M_2 \cup N \mid \rho(x, N) < \varepsilon \}$. Applying the function 

$$g(x) = \begin{cases} 
0, & x \in M_1, \\
\frac{\rho(x, N)}{\varepsilon}, & x \in N_\varepsilon, \\
1, & x \in M_2 \setminus N_\varepsilon,
\end{cases}$$

in (5) one obtains, after some computation, that if $\text{Vol}(M_1) \leq \text{Vol}(M_2 \setminus N_\varepsilon)$, 

$$\varepsilon^2 \lambda_1 < \frac{\text{Vol}(M) \text{Vol}(N_\varepsilon)}{\text{Vol}(M_1) \text{Vol}(M_2 - \frac{1}{2} \text{Vol}(N_\varepsilon))}.$$ 

If, moreover, $\text{Vol}(M_2 \setminus N_\varepsilon) \geq \frac{1}{2} \text{Vol}(M)$ then (6) implies for $\varepsilon = \frac{\lambda_1}{2\lambda_1}$ that 

$$\text{Vol}(M_1 \cup N_\varepsilon) > 2 \text{Vol}(M_1).$$ 

It is a matter of routine to derive (3) from (7). It should be mentioned that (7) also implies (4) but some additional work is required.

The obtained inequalities, upper bounds on $\text{diam}(M)$ and $\bar{p}(M)$, hold in general, whereas in previous works a similar result was obtained by Burger and Schroeder [BS] in the case only, when $M$ is a compact quotient of $\mathbb{H}^n$, $F$ being one of the rings $\mathbb{R}, \mathbb{C}, \mathbb{H},$ or $\mathbb{O}$ (this one for $n = 2$ only). Another work [B] uses the results of [BS] and some further analysis to obtain bounds on the diameter of a compact Riemannian manifold and its covers.
