it is clear that the development of all areas of real algebraic geometry will benefit greatly from the existence of *Géométrie algébrique réelle*.

HENRY C. KING
UNIVERSITY OF MARYLAND

Addison-Wesley has just reissued Serre’s 1968 treatise on 1-adic representations in their Advanced Book Classics series. This circumstance presents a welcome excuse for writing about the subject, and for placing Serre’s book in a historical perspective.

The theory of 1-adic representations is an outgrowth of the study of abelian varieties in positive characteristic, which was initiated by Hasse and Deuring (see, e.g., [3, 1]) and continued in Weil’s 1948 treatise [12]. Over the complex field C, an abelian variety $A$ of dimension $g$ may be viewed as an (algebrizable) complex torus $W/L$, where $L \approx \mathbb{Z}^{2g}$ is a lattice in the C-vector space $W$ of dimension $g$. The classical study of $A$ relies heavily on the lattice $L$, which is intrinsically the first homology group $H_1(A, \mathbb{Z})$. However, the quotients $L/nL$ (for $n \geq 1$) have a purely algebraic definition. Indeed, over $\mathbb{C}$ the quotient $L/nL$ is canonically the group

$$A[n] = \{P \in A \mid n \cdot P = 0\}$$

of $n$-division points on $A$. Over an arbitrary field $K$, one defines $A[n]$ as the group of points on $A$ (with values in a separable closure $\overline{K}$ of $K$) of order dividing $n$. When $n$ is prime to the characteristic of $K$, $A[n]$ is a free $\mathbb{Z}/n\mathbb{Z}$-module of rank $2g = 2 \dim A$, just as in the classical case. Moreover, the module $A[n]$ carries natural commuting actions of the Galois group $\text{Gal}({\overline{K}}/K)$ and the ring $\text{End}_K(A)$ of $K$-endomorphisms of $A$. Most information provided by $L$ can be extracted from the collection of groups $A[l^n]$ ($\nu \geq 1$), where $l$ is a fixed prime which is different from the characteristic of $K$.

In the 1950's, J. Tate suggested packaging together the groups $A[l']$ in the projective system

$$\cdots \to A[l^3] \to A[l^2] \to A[l]$$

in which the maps are induced by multiplication by $l$. The projective limit $T_l(A) = \lim_{l' \to A} A[l']$ is a free rank-2g module over $\mathbb{Z}_l$ (the $\mathbb{Z}_l$-adic Tate module attached to $A$). The $\mathbb{Q}_l$-adic Tate module

$$V_l(A) = T_l(A) \otimes_{\mathbb{Z}_l} \mathbb{Q}_l$$

is then a $\mathbb{Q}_l$-vector space of dimension $2g$. The natural continuous representation

$$\rho_{l,A} : \text{Gal}(\overline{K}/K) \to \text{Aut} T_l(A) \subseteq \text{Aut} V_l(A)$$

is the $l$-adic representation of $\text{Gal}(\overline{K}/K)$ attached to $A$.

The image of this representation is a compact, hence closed, subgroup of the $l$-adic Lie group $\text{Aut} V_l(A) \approx \text{GL}(2g, \mathbb{Q}_l)$. It is therefore a Lie subgroup of $\text{Aut} V_l(A)$. Its Lie algebra $\mathfrak{g}_l$ is then a subalgebra of $\text{gl}(V_l(A)) \approx \text{gl}(2g, \mathbb{Q}_l)$ which measures $\rho_{l,A}(\text{Gal}(\overline{K}/K))$ "up to finite groups." In particular, $\mathfrak{g}_l$ remains unchanged if $K$ is replaced by a finite extension of $K$ in $\overline{K}$.

A fundamental problem is to determine the Lie algebras $\mathfrak{g}_l$ attached to $A$ when the base field $K$ is a number field. The conjectured "answer" involves fixing an embedding $K \hookrightarrow \mathbb{C}$ and exploiting the resulting interpretation of $V_l = V_l(A)$ as $L \otimes \mathbb{Q}_l$, where $L$ is the lattice $H_l(A(C), Z)$, as above. The Hodge decomposition of $L \otimes \mathbb{C}$ defines a certain algebraic subgroup $\text{MT}(A)$ of the algebraic group $\text{GL}_{L \otimes \mathbb{Q}} \approx \text{GL}(2g)$ over $\mathbb{Q}$. This is the Mumford-Tate group of $A/C$. Its Lie algebra is a subalgebra $\mathfrak{h}$ of $\text{gl}(L \otimes \mathbb{Q})$, so that $\mathfrak{h}_l = \mathfrak{h} \otimes \mathbb{Q}_l$ is a subalgebra of $\text{gl}(V'_l)$. An important conjecture of Mumford and Tate [5, 7] states that $\mathfrak{g}_l = \mathfrak{h}_l$ inside $\text{gl}(V'_l)$ for each prime $l$. In particular, the family of Lie algebras $\mathfrak{g}_l$ is conjectured to be "independent of $l$.”

In proving special cases of this conjecture, it has often been useful to deal with the entire system $(\rho_{l,A})$ as $l$ varies, rather than to work with a single $\rho_{l,A}$. Transferring information from one $\rho_{l,A}$ to another is frequently possible because of the following compatibility, which was first stressed by Y. Taniyama [11]. Consider a prime ideal $p$ of the ring of integers of $K$ and try
to reduce $A \pmod{p}$.” The attempt succeeds for all $p$ outside a
finite set of primes (those at which $A$ has bad reduction). If $p$
lies outside this exceptional set, the representation $\rho_{l,A}$ is first of
all unramified at $p$ whenever $l$ is prime to $p$. This means that
we can associate to $p$ a distinguished conjugacy class in the image
of $\rho_{l,A}$, the set of Frobenius elements for $p$ in the image. Taking
the characteristic polynomial of any such Frobenius element, we
obtain a polynomial $P_{p,l}(T) \in \mathbb{Q}[T]$. The essential fact is that
this polynomial lies in $\mathbb{Q}[T]$ and depends only on $p$, but not on
the prime number $l$. This compatibility property is proved by
regarding $P_{p,l}$ as the characteristic polynomial of the Frobenius
endomorphism of $A \pmod{p}$, and applying results of Weil.

The Mumford-Tate conjecture was first proved for complex
multiplication (CM) abelian varieties as a corollary of the main
theorems of Shimura and Taniyama [10]. With this case under­
stood, the simplest case to attack was that for which $A$ is an el­
liptic curve ($g = 1$) with no complex multiplications, i.e., one for
which $e\text{End}_{\mathbb{F}}(A) = \mathbb{Z}$. This case was treated by J.-P. Serre in
the book under review, or rather in the original 1968 Benjamin
edition of the book. Serre showed that $g_l = gl(V_l) \approx gl(2, \mathbb{Q}_l)$, by
an argument which we now outline.

The first point is that, for non-CM elliptic curves, $V_l$ is irre­
ducible as a $g_l$-module. This is a theorem of Shafarevich, which
in turn depends on Siegel’s theorem on the finiteness of integral
points on curves. The second point is that $g_l$ cannot be contained
in the subalgebra $sl(V_l)$ of $gl(V_l)$, because of information on the
determinant of $\rho_{l,A}$ which is furnished by the $e_m$ pairings of
Weil. This leaves two possibilities for $g_l$: either $g_l$ is the desired
$gl(2, \mathbb{Q}_l)$, or else $g_l$ is a nonsplit Cartan subalgebra of $gl(2, \mathbb{Q}_l)$
(an abelian semisimple algebra coming from a quadratic field ex­
tension of $\mathbb{Q}_l$). The second possibility occurs for “half” the prime
numbers $l$ in the excluded case of an elliptic curve with complex
multiplication—those $l$ which remain inert in the field of com­
plex multiplication. The other primes $l$ in the CM case lead to
split Cartan subalgebras of $gl(2, \mathbb{Q}_l)$, which act reducibly on their
representation spaces. Serre showed that if at least one $g_l$ is a
Cartan subalgebra, then there are many $g_l$ which are split Cartan
subalgebras, even in the non-CM case. Once proved, this asser­
tion eliminates the second possibility in the non-CM case, since
split Cartan subalgebras of $gl(2, \mathbb{Q}_l)$ are incompatible with Sha­
farevich’s theorem. To prove the assertion, Serre made a detailed
study of semisimple abelian $l$-adic representations with certain local properties; this explains their appearance in the title of the book.

Since the publication of Serre’s book in 1968, there have been numerous advances in the theory of $l$-adic representations attached to abelian varieties over number fields. The most spectacular are contained in Faltings’ paper on the Mordell Conjecture [2], which proves two important facts about the representations $\rho_{l,A}$. First of all, Faltings proved that each $\rho_{l,A}$ is a semisimple representation of $\text{Gal}(\overline{K}/K)$ over $Q_l$. Secondly, Faltings proved the Tate Conjecture on endomorphisms of abelian varieties, which states that the natural map

$$\text{End}(A) \otimes Q_l \rightarrow \text{End}_{g_{l}}(V_l)$$

is an isomorphism for all $l$. This fact immediately rules out the Cartan subalgebra case in the elliptic curve argument, thus proving that $g_l = gl(2, Q_l)$ in the case of non-CM elliptic curves. Similarly, the theorems of Faltings easily prove the conjecture $g_l = h \otimes Q_l$ in the case of abelian varieties with real multiplications: $A$’s whose endomorphism algebras are totally real number fields of degree $2 \dim(A)$ over $Q$. Finally, using Faltings’ theorems, and a family of new ideas suggested by papers of Yu. Zarhin, Serre proved several years ago [9] that $g_l = h \otimes Q_l$ whenever $A$ has no nontrivial endomorphisms and the dimension of $A$ is 2, 6, or an odd number.

Despite these recent developments, the 1968 book of Serre is hardly outmoded. For one thing, as the cover of the new edition reminds us, it’s the only book on the subject. More importantly, it can be viewed as a toolbox which contains clear and concise explanations of fundamental facts about a series of related topics: abstract $l$-adic representations, Hodge-Tate decompositions, elliptic curves, $L$-functions, etc. The algebraic groups introduced in the book form the toric part (or “Serre group”) of the Taniyama group introduced in [4] (see also [6]). The tools introduced in this book have been, and will continue to be, extremely useful in other contexts, such as the study of $l$-adic representations arising from étale cohomology groups $H^i(X_{\overline{K}}, Q_l)$ with $i > 1$ (in particular, representations associated to modular forms). The book remains a valuable textbook and reference.

The new edition differs from the old one in minor ways. First, misprints in the first edition have been corrected. (A list of errata to the first edition was given at the end of [8].) Secondly, a number of remarks concerning recent developments have been squeezed
into the original text. (They are prefaced by arrows → and appear in heavy type.) Thirdly, a 42-item bibliography of post-1968 articles has been added. Finally, a new two-page “Special Preface” begins the volume. In this preface, the condition “Endₖ A = Z” should read “Endₓ A = Z,” as was pointed out to me by the author.
