

WAVELETS ON GENERAL LATTICES, ASSOCIATED WITH GENERAL EXPANDING MAPS OF \mathbf{R}^n

A. CALOGERO

(Communicated by Stuart Antman)

ABSTRACT. In the context of a general lattice Γ in \mathbf{R}^n and a strictly expanding map M which preserves the lattice, we characterize all the wavelet families, all the MSF wavelets, all the multiwavelets associated with a Multiresolution Analysis (MRA) of multiplicity $d \geq 1$, and all the scaling functions. Moreover, we give several examples: in particular, we construct a single, MRA and $C^\infty(\mathbf{R}^n)$ wavelet, which is nonseparable and with compactly supported Fourier transform.

1. INTRODUCTION

An orthonormal wavelet is a function $\psi \in L^2(\mathbf{R})$ such that the set

$$(1) \quad \{\psi_{j,k} \equiv 2^{j/2}\psi(2^j x - k) : j, k \in \mathbf{Z}\}$$

is an orthonormal basis for $L^2(\mathbf{R})$. A complete characterization of these wavelets is given by the equations

$$(I) \quad \begin{aligned} a) \quad & \sum_{j \in \mathbf{Z}} |\widehat{\psi}(2^j \xi)|^2 = 1 && \text{a.e. } \xi \in \mathbf{R}, \\ b) \quad & \sum_{j=0}^{\infty} \widehat{\psi}(2^j \xi) \overline{\widehat{\psi}(2^j(\xi + 2k\pi))} = 0 && \text{a.e. } \xi \in \mathbf{R}, k \in 2\mathbf{Z} + 1, \end{aligned}$$

together with the assumption $\|\psi\|_2 \geq 1$. These two equations have been known since the beginning of the theory of wavelets (see [L1] and [L2]), but the proof of this characterization did not appear in the literature until recently (see [Gr], [W], [H-W-W3], [Ga]). A much more direct argument gives us two equations that characterize the orthonormality of the system $\{\psi_{j,k}\}$, $j, k \in \mathbf{Z}$:

$$(II) \quad \begin{aligned} a) \quad & \sum_{k \in \mathbf{Z}} |\widehat{\psi}(\xi + 2k\pi)|^2 = 1 && \text{a.e. } \xi \in \mathbf{R}, \\ b) \quad & \sum_{k \in \mathbf{Z}} \widehat{\psi}(2^j(\xi + 2k\pi)) \overline{\widehat{\psi}(\xi + 2k\pi)} = 0 && \text{a.e. } \xi \in \mathbf{R}, \text{ if } j > 0. \end{aligned}$$

These two equations clearly must be a consequence of (I) (see [H-W], Chapter 7).

These four equations are most useful for the construction of very general examples of wavelets. An immediate consequence is that $|\widehat{\psi}(\xi)| \leq 1$ a.e. when ψ satisfy

Key words and phrases. Wavelets, multiresolution analysis (MRA), general lattices in \mathbf{R}^n , MSF wavelets, multiwavelets.

(I) a), or (II) b). Integrating the series in (II) a) on $[0, 2\pi)$ it then follows that $\text{meas}(\text{supp } \widehat{\psi}) \geq 2\pi$ and we have equality if and only if $|\widehat{\psi}| = \chi_K$, with K a measurable subset of \mathbf{R} of measure $|K| = 2\pi$. Wavelets of this last described form are known as Minimally Supported Frequency (MSF) wavelets. It is an easy exercise that the MSF wavelets are characterized by the equations (I) a) and (II) a) (see [H–W]).

Another important way for constructing wavelets is the use of the Multiresolution Analysis (MRA) method which yields what is known as the MRA wavelets. This type of wavelets has been completely characterized by Gripenberg and Wang ([Gr], [W]) in the following way: the wavelet ψ is an MRA wavelet if and only if

$$(2) \quad D_\psi(\xi) = \sum_{j=1}^{\infty} \sum_{k \in \mathbf{Z}} |\widehat{\psi}(2^j(\xi + 2k\pi))|^2 = 1 \quad \text{a.e. } \xi \in \mathbf{R}.$$

These notions extend to \mathbf{R}^n , $n > 1$. Certain needed changes are obvious (we translate by lattice points and the preservation of the norm is affected by multiplying ψ in (1) by $2^{jn/2}$ instead of $2^{j/2}$). Other changes, however, are more crucial and of a different character. There is a natural extension of the notion of an MRA involving one scaling function. This leads to the same characterization (2) in the n -dimensional case. However, an easy computation shows the necessity of introducing $2^n - 1$ functions $\psi^1, \psi^2, \dots, \psi^L$, $L = 2^n - 1$, that generate the wavelets basis. Moreover, another way in which more than one generator appears is by considering an MRA given by more than one scaling function. Taking into account these features one can, again, characterize all these wavelets by two equations [F–G–W–W] and the basic structure of the 1-dimensional proof applies. This general approach also includes singly generated wavelets (which, of course, cannot be MRA wavelets).

The principal purpose of our work is to show that all this can be extended to the case where the “dilations” are affected by using more general matrices M (not just $M = 2I_n$) and the translations involve a general lattice. In fact, we obtain a theorem that characterizes these more general wavelets and, also, one that characterizes MRA wavelets and scaling functions. Let us be explicit: in the paper [Ca1] that is to appear in the Journal of Geometric Analysis we obtain a generalization of (I) a), b). The characterization of MSF wavelets offers no surprises. We do this explicitly in the second section. Others have considered these dilations and lattices in the general MRA case: Gröchenig, Madych and Strichartz (we will refer to them below). In the third section we give a characterization of the appropriate Multiresolution Analyses and associated scaling functions (that extend the 1-dimensional result in [H–W], Chapter 7). In this connection see also [Ma].

An interesting feature of these general wavelets is that for certain dilations we can construct singly generated MRA wavelets. These and other observations will be made in the fourth section where we list several examples of these more general wavelets. We include a specific method for “smoothing” an MSF wavelet of the plane that, almost certainly, is applicable in much more general situations.

Finally, we wish to thank Guido Weiss for his invaluable advice and help.

2. CHARACTERIZATION OF WAVELET FAMILIES AND MSF WAVELETS

In the mathematical literature there are several papers devoted to the study of wavelets and multiresolution analyses from the point of view of general lattices. The papers [Ma] and [S1] contain detailed illustrations of multiresolution analyses,

generated by lattice translates of the scaling function and their dilations. Moreover, they show how to construct orthonormal wavelets bases in this context. In particular, Gröchenig and Madych [G–M], and Strichartz [S2], starting from self-affine and self-similar tilings of \mathbf{R}^n , construct multiresolution analyses and wavelet bases with the translation lattice and scaling naturally associated with the tiling.

We consider a *lattice* Γ of \mathbf{R}^n as a discrete additive subgroup of \mathbf{R}^n given by the integral linear combinations of n independent vectors. In other words, $\Gamma = A\mathbf{Z}^n$ where A is a $n \times n$ real matrix with $\det A > 0$. Moreover we denote by \mathcal{C} the *fundamental domain* of Γ which is the set $\mathcal{C} = A[-1/2, +1/2)^n$.

We define the *dual lattice* Γ^* as the set of points $\gamma^* \in \mathbf{R}^n$ such that $\langle \gamma, \gamma^* \rangle \in 2\pi\mathbf{Z}$ for all $\gamma \in \Gamma$. It is immediate to see that $\Gamma^* = 2\pi(A^*)^{-1}\mathbf{Z}^n$. Note that for $n = 1$ and $\Gamma = \mathbf{Z}$, we simply have $\Gamma^* = 2\pi\mathbf{Z}$.

We say that a linear transformation $M : \mathbf{R}^n \rightarrow \mathbf{R}^n$ is an *acceptable dilation* for Γ [Ma] if it satisfies the following conditions:

- (1) M is *strictly expanding*, i.e. all the eigenvalues λ of M satisfy $|\lambda| > 1$,
- (2) M *preserves the lattice* Γ , i.e. $M\Gamma \subseteq \Gamma$.

It is easy to see that $m = |\det M|$ is an integer ≥ 2 . We denote by M^* the dual map of M .

A family of functions $\Psi = \{\psi^1, \psi^2, \dots, \psi^L\} \subset L^2(\mathbf{R}^n)$ is a *family of orthonormal wavelets* when

$$(1') \quad \{\psi_{j,\gamma}^l : \gamma \in \Gamma, j \in \mathbf{Z}, l = 1, \dots, L\}$$

is an orthonormal basis for $L^2(\mathbf{R}^n)$, where $\psi_{j,\gamma}^l = m^{j/2}\psi^l(M^j x - \gamma)$.

In [Ca1] we have characterized these wavelet families as follows:

Theorem 1. *Suppose $\Psi = \{\psi^1, \psi^2, \dots, \psi^L\} \subset L^2(\mathbf{R}^n)$, with $\|\psi^l\|_2 \geq 1$ for $1 \leq l \leq L$. Then Ψ is a family of orthonormal wavelets if and only if the functions $\psi^1, \psi^2, \dots, \psi^L$ satisfy the following two equations:*

$$(I') \quad \begin{aligned} a) & \sum_{l=1}^L \sum_{j \in \mathbf{Z}} |\widehat{\psi}^l(M^{*j}\xi)|^2 = \det A \quad \text{a.e. } \xi \in \mathbf{R}^n, \\ b) & \sum_{l=1}^L \sum_{j=0}^{\infty} \widehat{\psi}^l(M^{*j}\xi) \overline{\widehat{\psi}^l(M^{*j}(\xi + \gamma^*))} = 0 \quad \text{a.e. } \xi \in \mathbf{R}^n, \gamma^* \in \Gamma^* \setminus M^*\Gamma^*. \end{aligned}$$

This characterization follows the strategy of the proof of Frazier, Garrigós, Wang and Weiss in the classical case. However, there are several differences. For example, in the general case M will not be isotropic, since there may be different eigenvalues. Moreover, M may involve a rotation, so that a neighborhood U of the origin in general will not be contained in MU . Thus, we have to take into account several features of lattices which do not show up in the classical case. In some parts of the proof this results in more technical complications; but, in other parts, we have to prove additional results in order to obtain finer estimates.

We recall (see [H–W–W1] and [H–W–W2]) that a Minimally Supported Frequency (MSF) wavelet is a wavelet in $L^2(\mathbf{R}^n)$ such that the measure of $\text{supp}(\widehat{\psi})$ is minimal. Here, if ψ is an MSF wavelet, then $|\widehat{\psi}| = \sqrt{\det A} \cdot \chi_T$ for some measurable set T in \mathbf{R}^n with $\text{meas}(T) = (2\pi)^n (\det A)^{-1}$. Fang and Wang present a thorough study of MSF wavelets in $L^2(\mathbf{R})$ in the classical context. Dai, Larson and Speegle [D–L–S1] proved that for $\Gamma = \mathbf{Z}^n$ and every acceptable map there exists an MSF wavelet. In other words, there always exists a measurable set $K \subset \mathbf{R}^n$ such that

the single function ψ , defined by $\widehat{\psi} = \text{const} \cdot \chi_K$, is an orthonormal wavelet for $L^2(\mathbf{R}^n)$. This type of set K is called a wavelet set. Soardi and Weiland [S–W] provided explicit examples of such K , for $\Gamma = \mathbf{Z}^n$ and $M = 2I$.

The characterization of all the MSF wavelets can be given in terms of the following definition.

Definition 1. Let us define a *partition* of a measurable set $K \subseteq \mathbf{R}^n$ as a countable collection $\{K_n\}$ of measurable subsets of K , such that $K_n \cap K_m$ has measure zero if $n \neq m$ and such that $\bigcup_n K_n = K$ up to a set of measure zero.

The characterization of all the MSF follows directly from the equations (I').

Theorem 2. Let ψ be a function such that $|\widehat{\psi}| = \alpha \cdot \chi_T$, for some measurable set T and some positive constant α . Then ψ is an MSF wavelet if and only if the following three conditions are satisfied:

- (a) $\alpha^2 = \det A$;
- (b) $\{M^{*j}T : j \in \mathbf{Z}\}$ is a partition of \mathbf{R}^n ;
- (c) $\{T + \gamma^* : \gamma^* \in \Gamma^*\}$ is a partition of \mathbf{R}^n .

Another characterization of MSF wavelets can be found in [B–M–M]. The problem which naturally arises is how to construct the support T of the Fourier transform of an MSF wavelet. In [Ca1] we give a general and constructive method to do this and apply this method to produce some examples which, in particular, involve the quincunx lattice.

3. CHARACTERIZATION OF MULTI-WAVELET FAMILIES AND SCALING FUNCTIONS

In the wavelet literature and, in particular, in the study of digital signal processing there is an increasing interest in wavelets associated with an MRA of multiplicity $d > 1$, the so called multiwavelets (see for example [H], [Ma], [D–S]). Recent papers show how to convert a single input stream to multi-inputs which give samples of the data at half-intervals. An example is the Geronimo–Hardin–Massopust multiwavelets [G–H–M] which give experimental results in compression.

Let us recall the definition of Multiresolution Analyses (MRA) of multiplicity d . We say that a sequence $\{V_j\}$, $j \in \mathbf{Z}$, of closed subspaces of $L^2(\mathbf{R}^n)$ is a *multiresolution analysis of multiplicity d* if the following four conditions are satisfied:

- (i) $\bigcup_{j=-\infty}^{+\infty} V_j$ is dense in $L^2(\mathbf{R}^n)$;
- (ii) $V_{j-1} \subseteq V_j$, for every $j \in \mathbf{Z}$;
- (iii) for every $f \in L^2(\mathbf{R}^n)$ and $j \in \mathbf{Z}$ we have $f(x) \in V_j \iff f(M^{-j}x) \in V_0$;
- (iv) there exist d functions $\varphi_1, \varphi_2, \dots, \varphi_d$ in V_0 such that $\{\varphi_h(x - \gamma); \gamma \in \Gamma, h = 1, \dots, d\}$ is an orthonormal basis for V_0 .

The functions $\varphi_1, \varphi_2, \dots, \varphi_d$ are called the *scaling functions* of the MRA. Furthermore the wavelets associated with an MRA of multiplicity d are called multiwavelets.

In the study of MRA wavelet families, we note an interesting difference between the dyadic map and some general acceptable maps of \mathbf{R}^n . In the first case one cannot have a single MRA wavelet if $n > 1$, while for such M it suffices to consider the case $m = |\det M| = 2$ to construct such a single ψ , as shown in section 4.

Theorem 3. Let $\Psi = \{\psi^1, \psi^2, \dots, \psi^{(m-1)d}\} \subset L^2(\mathbf{R}^n)$ be a wavelet family associated with the lattice Γ and the acceptable map M . Ψ is an MRA wavelet family of

multiplicity d if and only if

$$(2') \quad D_{\Psi}(\xi) = \sum_{l=1}^{(m-1)d} \sum_{j=1}^{\infty} \sum_{\gamma^* \in \Gamma^*} |\widehat{\psi}^l(M^{*j}(\xi + \gamma^*))|^2 = d \cdot \det A \quad \text{a.e. } \xi \in \mathbf{R}^n.$$

A proof of this result is given in [C–G] as a consequence of a characterization of wavelet families arising from biorthogonal MRA's of multiplicity d . Given the result of Theorem 3, it is of some interest to know which functions can be scaling functions of an MRA. Let us mention existing results on this subject.

The characterization of single scaling functions was previously known in some particular cases: for $n = 1$ and so called localized scaling functions (see e.g. [K–L], [Co]); for scaling functions which are characteristic functions of a prototile of a self-similar tiling of \mathbf{R}^n [G–M]; for certain scaling functions constructed by means of tilings of \mathbf{R}^n [S1]. The book [H–W] (see also [H–W–W3]) contains a characterization of all scaling functions in the case $n = 1$. Madych, in this context of general lattices and acceptable dilations, characterizes the single functions φ which generate an MRA and those whose scaling functions are characteristic functions are completely described.

In the case $d > 1$, Geronimo, Hardin and Massopust [G–H–M] give necessary and sufficient conditions for certain functions, constructed using fractal functions, to form an MRA of $L^2(\mathbf{R})$. Hervé [H] studied the scaling filters which yield an MRA of multiplicity $d > 1$, while De Michele and Soardi [D–S] studied the basic properties of MRA of multiplicity d .

We can prove the following general characterization (see [Ca2]).

Theorem 4. *Let $\varphi_1, \varphi_2, \dots, \varphi_d$ be functions of $L^2(\mathbf{R}^n)$ and, for every $j \in \mathbf{Z}$, let*

$$V_j = \overline{\text{span}\{m^{j/2}\varphi_h(M^j x - \gamma) : \gamma \in \Gamma, h = 1, \dots, d\}}.$$

Then the scale of spaces $\{V_j\}_{j \in \mathbf{Z}}$ is an MRA of multiplicity d with scaling functions $\varphi_1, \varphi_2, \dots, \varphi_d$ if and only if for a.e. $\xi \in \mathbf{R}^n$ the following conditions hold:

$$(3) \quad \sum_{\gamma^* \in \Gamma^*} |\widehat{\varphi}_h(\xi + \gamma^*)|^2 = \det A \quad \text{for } h = 1, \dots, d,$$

$$(4) \quad \sum_{\gamma^* \in \Gamma^*} \widehat{\varphi}_h(\xi + \gamma^*) \overline{\widehat{\varphi}_k(\xi + \gamma^*)} = 0 \quad \text{for } h, k = 1, \dots, d \text{ with } k \neq h,$$

$$(5) \quad \lim_{j \rightarrow +\infty} \sum_{h=1}^d |\widehat{\varphi}_h(M^{*-j}\xi)|^2 = \det A,$$

$$(6) \quad \widehat{\varphi}_h(M^*\xi) = \sum_{k=1}^d m_{hk}(\xi) \widehat{\varphi}_k(\xi) \quad \text{for } h = 1, \dots, d,$$

for some functions m_{hk} of $L^2(\mathbf{R}^n/\Gamma^*)$.

We recall that in the case $d = 1$, the function m which satisfies relation (6) is called a low-pass filter.

4. EXAMPLES OF MSF AND MRA WAVELETS, OF MULTIWAVELETS AND A $C^\infty(\mathbf{R}^2)$, NONSEPARABLE WAVELET WITH COMPACTLY SUPPORTED FOURIER TRANSFORM

In this last section we give some examples of wavelets constructed from the previous characterizations. In particular, we concentrate our attention on the case $\Gamma = \mathbf{Z}^2$ and the acceptable map $M(x, y) = (x - y, x + y)$ which was studied in some detail by Cohen and Daubechies [C-D]. For this map $m = |\det M| = 2$. Clearly $M^*(x, y) = (x + y, y - x)$ and $M^{*-1}(x, y) = ((x - y)/2, (y + x)/2)$.

In the first example we produce an MRA, MSF wavelet ψ_0 . In the second example, we smooth the wavelet ψ_0 . So we obtain a single $C^\infty(\mathbf{R}^2)$, nonseparable wavelet with compactly supported Fourier transform. Using the ideas of the construction of ψ_0 , in the third example, we present two wavelets ψ_1 and ψ_2 that are multiwavelets associated with an MRA of multiplicity 2. In the fourth example, we consider a different map and give examples of singly generated wavelts in \mathbf{R}^n .

Example 1. Let us define $T = M^*\mathcal{C}^* \setminus \mathcal{C}^*$. We recall that $\mathcal{C}^* = [-\pi, \pi)^2$. We claim that $\widehat{\psi}_0 = \chi_T$ defines a wavelet ψ_0 associated with a multiresolution analysis of multiplicity 1. Moreover, ψ_0 is also an MSF wavelet.

FIGURE 1. The support T of the Fourier transform of the wavelet ψ_0 .

The proof is an easy application of Theorems 2 and 3. We do not give this proof here, but we indicate how it is possible to construct the wavelet ψ_0 starting from the scaling function φ_0 of the MRA. We define the scale of spaces $\{V_j\}_{j \in \mathbf{Z}}$ of $L^2(\mathbf{R}^n)$, $V_j = \overline{\text{span}\{2^{j/2}\varphi_0(M^j x - \gamma) : \gamma \in \mathbf{Z}^2\}}$, with the scaling function $\widehat{\varphi}_0 = \chi_{\mathcal{C}^*}$ (see Theorem 4). Moreover an easy computation shows that the low-pass filter is $m_0(\xi) = \sum_{\gamma^* \in 2\pi\mathbf{Z}^2} \chi_{(M^{*-1}\mathcal{C}^*)}(\xi + \gamma^*)$.

With this fixed map and lattice, we use that a generic scaling function φ and the associated low-pass filter m produce the wavelet ψ by

$$(7) \quad \widehat{\psi}(M^*(x, y)) = \overline{m(x + \pi, y + \pi)} \widehat{\varphi}(x, y) e^{i(x+y)/2}.$$

We recall that $e^{i(x+y)/2}$ is called the phase and $p(x, y) = \overline{m(x + \pi, y + \pi)} e^{i(x+y)/2}$ is called the high-pass filter. Moreover, we remember (see [D-S]) that p is such that

the matrix

$$\begin{pmatrix} m(x, y) & m(x + \pi, y + \pi) \\ p(x, y) & p(x + \pi, y + \pi) \end{pmatrix}$$

is unitary, a.e. This implies the so called filter relation,

$$|m(x, y)|^2 + |m(x + \pi, y + \pi)|^2 = 1.$$

Returning to our example, since the wavelet ψ_0 is MSF, we can choose an arbitrary phase in (7) and it is an easy exercise to obtain ψ_0 from φ_0 . Now the question is the following: in order to construct a $C^\infty(\mathbf{R}^2)$ wavelet, is it possible to smooth the previous wavelet ψ_0 ? The next example gives us a positive answer.

Example 2. In order to answer the previous question, we do not smooth directly the wavelet ψ_0 , but we smooth the filter m_0 . For every fixed ϵ , with $0 < \epsilon \leq \pi$, we construct two low-pass filters, \widetilde{m}_ϵ and m_ϵ . We will see that the construction of \widetilde{m}_ϵ is very easy but also that this function belongs only to $\text{Lip}_1(\mathbf{R}^2)$. However, the idea underlying the construction of \widetilde{m}_ϵ allows us to produce a more complicated function $m_\epsilon \in C^\infty(\mathbf{R}^2)$.

These constructions are similar to the one that produces the Lemarié–Meyer wavelet from the Shannon wavelet. We begin by defining a $C^\infty(\mathbf{R})$ function θ with the following properties:

$$\begin{aligned} 0 \leq \theta(t) \leq 1 \quad \text{and} \quad \theta(t) = 1 - \theta(1 - t) \quad \text{for every } t \in \mathbf{R}, \\ \theta(t) = 0 \quad \text{if } t \leq 0, \quad \theta(t) = 1 \quad \text{if } t \geq 1. \end{aligned}$$

Moreover let us define the function $\nu(t) = \cos(\frac{\pi}{2}\theta(t))$. Clearly $\nu \in C^\infty(\mathbf{R})$ and $\nu^2(t) + \nu^2(1 - t) = 1$. Starting from this function ν , we construct the low-pass filters.

Let us fix ϵ , with $0 < \epsilon \leq \pi$. For every $(x, y) \in [-\pi, \pi]^2$ we set

$$\widetilde{m}_\epsilon(x, y) = \nu[(|x| + |y| - \pi + \epsilon)/(2\epsilon)].$$

Next, we extend periodically the definition of \widetilde{m}_ϵ so that, for every $\gamma^* \in 2\pi\mathbf{Z}^2 \setminus \{0\}$ and $\xi \in [-\pi, \pi]^2$, we have $\widetilde{m}_\epsilon(\xi + \gamma^*) = \widetilde{m}_\epsilon(\xi)$. Clearly, $\widetilde{m}_\epsilon \in L^2(\mathbf{R}^2/\Gamma^*)$ and belongs to $\text{Lip}_1(\mathbf{R}^2)$. It is easy to verify that \widetilde{m}_ϵ is a low-pass filter.

Let us construct the second low-pass filter m_ϵ . For every $(x, y) \in \mathbf{R}^2$, we set

$$\begin{aligned} n_\epsilon(x, y) = \nu[(x + y - \pi + \epsilon)/(2\epsilon)]\nu[(x - y - \pi + \epsilon)/(2\epsilon)] \\ \cdot \nu[(-x + y - \pi + \epsilon)/(2\epsilon)]\nu[(-x - y - \pi + \epsilon)/(2\epsilon)]. \end{aligned}$$

Since $\text{supp}(n_\epsilon) \subseteq [-\pi - \epsilon, \pi + \epsilon]^2$, we define the function N_ϵ by periodizing n_ϵ :

$$N_\epsilon(\xi) = \sum_{\gamma^* \in 2\pi\mathbf{Z}^2} n_\epsilon(\xi + \gamma^*).$$

Clearly, $N_\epsilon \in L^2(\mathbf{R}^2/\Gamma^*) \cap C^\infty(\mathbf{R}^2)$, but the filter relation is not satisfied. Since $N_\epsilon^2(x, y) + N_\epsilon^2(x + \pi, y + \pi) > 0$, we can prove that the function

$$m_\epsilon(x, y) = \frac{N_\epsilon(x, y)}{\sqrt{N_\epsilon^2(x, y) + N_\epsilon^2(x + \pi, y + \pi)}}, \quad \text{for every } (x, y) \in \mathbf{R}^2,$$

is a low-pass filter belonging to $C^\infty(\mathbf{R}^2)$. We remark that $\text{supp}(\widetilde{m}_\epsilon) = \text{supp}(m_\epsilon)$.

FIGURE 2. The function $|\widehat{\psi}_\epsilon|$, with $\epsilon = 2/5$.

Theorem 5. For every fixed ϵ , with $0 < \epsilon \leq \pi/5$, the function ψ_ϵ defined by

$$\widehat{\psi}_\epsilon(x, y) = \prod_{j=2}^5 m_\epsilon(M^{*-j}(x, y)) m_\epsilon(M^{*-1}(x, y) + (\pi, \pi)) e^{ix/2},$$

is a wavelet of $L^2(\mathbf{R}^2)$ with lattice $\Gamma = \mathbf{Z}^2$ and acceptable map M . This wavelet is MRA and belongs to $C^\infty(\mathbf{R}^2)$. Moreover, ψ_ϵ is nonseparable and with compactly supported Fourier transform.

The proof of Theorem 5 uses (7) and the relation

$$(8) \quad \widehat{\varphi}_\epsilon(\xi) = \prod_{j=1}^{\infty} m_\epsilon(M^{*-j}\xi),$$

where φ_ϵ is the scaling function of the associated MRA.

We remark that the assumption on ϵ guarantees that the set

$$\text{supp}(\widehat{\varphi}_\epsilon) = \bigcap_{j \geq 1} (\text{supp}(m_\epsilon(M^{*-j}\cdot)))$$

is a compact and connected subset of $[-2\pi, 2\pi]^2$. Hence, $\text{supp}(\widehat{\psi}_\epsilon)$ is also compact and connected. These properties together with (8) show that $\widehat{\varphi}_\epsilon$ is the product of only four factors.

It is possible to show that if we assume $\pi/5 < \epsilon \leq \pi$, then we can construct again an MRA wavelet ψ_ϵ but the scaling function φ_ϵ is not a finite product of functions and $\text{supp}(\widehat{\varphi}_\epsilon)$ is unbounded.

Finally, similar results hold with \widetilde{m}_ϵ in place of m_ϵ ; the corresponding functions $\widehat{\varphi}_\epsilon$ and $\widehat{\psi}_\epsilon$ are simpler to describe but less regular.

Example 3. Let us define $\Psi = \{\psi^1, \psi^2\}$ such that $\widehat{\psi}^1 = \chi_{T_1}$ and $\widehat{\psi}^2 = \chi_{T_2}$.

We claim that Ψ is a wavelet family associated with a multiresolution analyses of multiplicity 2. The proof uses Theorems 1 and 3.

Example 4. In this last example, we want to show that for every integer $n \geq 2$, there exists an easy MRA wavelet on the lattice $\Gamma = \mathbf{Z}^n$, associated with an acceptable map M_n with $\det M_n = 2$. Let $\widetilde{\psi} \in L^2(\mathbf{R})$ be an MRA wavelet on the

FIGURE 3. The supports T_1 and T_2 of $\widehat{\psi}^1$ and $\widehat{\psi}^2$ respectively.

usual lattice $\Gamma = \mathbf{Z}$, associated with the usual dyadic map. Moreover, let $\widetilde{\varphi}$ be the scaling function of the MRA. Let us fix $n \geq 2$ and let us consider the map $M_n^*(x_1, x_2, \dots, x_n) = (2x_n, x_1, x_2, \dots, x_{n-1})$. We claim that the function ψ such that

$$\widehat{\psi}(x_1, x_2, \dots, x_n) = \widetilde{\psi}(x_1)\widetilde{\varphi}(x_2)\widetilde{\varphi}(x_3)\cdots\widetilde{\varphi}(x_n)$$

is an MRA wavelet on the lattice \mathbf{Z}^n , associated with the map M_n . The proof is an easy exercise.
