

On a Problem of Hasse

By H. Zassenhaus and J. Liang

Abstract. A p -adic method to construct explicitly a generating automorphism of the Hilbert classfield over $\mathbf{Q}(\sqrt{-47})$ and to perform Tshirnhausen transformations for generating equations of the real subfield is developed.

I. Let $f(x)$ be a monic polynomial with coefficients in \mathbf{Z} , irreducible of degree n over \mathbf{Q} , with θ a real root, let

$$\begin{aligned} k &= \mathbf{Q}(\sqrt{d}), & d < 0 \\ E &= \mathbf{Q}(\theta), \end{aligned}$$

$K = E(\sqrt{d})$ and K is normal over \mathbf{Q} and cyclic of degree n over k . How to find a generating element of $G(K/k)$, where $G(K/k)$ is the Galois group of K over k ?

Here we give a p -adic method to construct such an automorphism. In the end, we shall give some examples to demonstrate our method.

By a theorem given in [2] there are infinitely many rational prime numbers p which decompose in k into the product of two distinct prime ideals which stay indecomposed in K . Those are the ones with decomposition group equal to $G(K/k)$ and not dividing the discriminant of K over \mathbf{Q} . Among them there is one which does not even divide the characteristic b of the factor module of \mathfrak{D}_K over $\mathfrak{D}_E \cdot \mathfrak{D}_k$. (We denote by \mathfrak{D}_F the ring of the algebraic integers of the algebraic number field F .)

Let $p = \mathfrak{p}_1 \mathfrak{p}_2$ in k , $\mathfrak{p}_1 \neq \mathfrak{p}_2$ are prime ideals in k and let $\mathfrak{P}_i = \mathfrak{p}_i \mathfrak{D}_K$, $i = 1, 2$, \mathfrak{P}_i prime ideals in \mathfrak{D}_K . Since k is imaginary quadratic the two prime ideals $\mathfrak{p}_1, \mathfrak{p}_2$ are complex conjugate. The same applies to $\mathfrak{P}_1, \mathfrak{P}_2$.

Then we know there exists an automorphism σ , namely the Frobenius automorphism in G such that

$$\sigma \xi \equiv \xi^p \pmod{\mathfrak{P}_1} \quad \text{for every } \xi \in \mathfrak{D}_K$$

and in particular,

$$\sigma \theta \equiv \theta^p \pmod{\mathfrak{P}_1}.$$

Let $\sigma_{1,0}(x) \equiv x^p \pmod{f(x)}$ where $\sigma_{1,0}(x)$ is a polynomial of $\mathbf{Z}[x]$ of degree less than n . It follows that $\sigma_{1,0}(\theta) = \theta^p \equiv \sigma \theta \pmod{\mathfrak{P}_1}$.

Since p is unramified in K , we have p as \mathfrak{P}_1 -adic generator of \mathfrak{P}_1 , i.e. $p \in \mathfrak{P}_1$, but $p \notin \mathfrak{P}_1^2$.

In order to obtain the action of σ on θ modulo powers of \mathfrak{P}_1 , we proceed as follows: let $\sigma \theta \equiv \sigma_{1,0}(\theta) + p g_1(\theta) \pmod{\mathfrak{P}_1^2}$ where $g_1(x)$ is a polynomial of $\mathbf{Z}[x]$ of degree less than n .

How to find g_1 ?

We know that

$$(*) \quad f(\sigma_{1,0}(\theta) + p g_1(\theta)) \equiv 0 \pmod{\mathfrak{P}_1^2}$$

Received November 13, 1968.

and by Taylor-Maclaurin

$$(**) \quad f(\sigma_{1,0}(\theta) + pg_1(\theta)) \equiv f(\sigma_{1,0}(\theta)) + pf'(\sigma_{1,0}(\theta))g_1(\theta) \pmod{\mathfrak{P}_1^2}.$$

Since

$$(***) \quad f(\sigma_{1,0}(\theta)) \equiv 0 \pmod{\mathfrak{P}_1}$$

we can write $f(\sigma_{1,0}(x)) \equiv pf_1(x) \pmod{f}$ where f_1 is a polynomial of $\mathbf{Z}[x]$ of degree less than n .

From (*), (**), (***), we then obtain

$$g_1(\theta) = -f_1(\theta)/f'(\sigma_{1,0}(\theta)) \pmod{\mathfrak{P}_1}.$$

Continue this process for higher powers of \mathfrak{P}_1 until we reach an exponent $2^{\nu+1}$. The number ν is to be determined later and a bound for the number ν was given in [1].

In the same manner, we should compute $\sigma\theta$ modulo powers of \mathfrak{P}_2 . Noting that \mathfrak{P}_1 and \mathfrak{P}_2 are complex conjugates, but that θ is real and that $\sigma\theta \equiv \theta^p \pmod{\mathfrak{P}_1}$, it follows if τ is the automorphism of K over \mathbf{Q} such that $\tau: a + ci \rightarrow a - ci$, a, c real, then applying τ to the above congruence, we have

$$(\tau\sigma)\theta \equiv \theta^p \pmod{\mathfrak{P}_2}$$

and $(\tau\sigma\tau^{-1})\theta \equiv \theta^p \pmod{\mathfrak{P}_2}$ and hence $\tau\sigma\tau^{-1} \neq \sigma$. On the other hand $G(K/k)$ is normal in $\text{Aut}(K/\mathbf{Q}) = \langle \tau, G(K/k) \rangle$ and therefore $(\tau\sigma\tau^{-1})\theta = (\sigma^j)\theta$ where $1 < j < n$, so $\sigma\theta \equiv h^*(\theta) \pmod{\mathfrak{P}_2}$ where $h^*(\theta) \equiv (\sigma^j)\theta \pmod{\mathfrak{P}_1}$.

Again, let $\sigma_{2,0}(x) \equiv h^*(x) \pmod{f(x)}$ we then have

$$\sigma\theta \equiv \sigma_{2,0}(\theta) \pmod{\mathfrak{P}_2}.$$

Proceed from here as before to obtain actions of σ modulo powers of \mathfrak{P}_2 until $\mathfrak{P}_2^{2^{\nu+1}}$. We then have the following congruence conditions:

$$\begin{aligned} \sigma\theta &\equiv \sigma_{1,0}(\theta) \pmod{\mathfrak{P}_1}, \\ \sigma\theta &\equiv \sigma_{1,1}(\theta) \pmod{\mathfrak{P}_1^2}, \\ &\vdots \\ &\vdots \\ \sigma\theta &\equiv \sigma_{1,\nu+1}(\theta) \pmod{\mathfrak{P}_1^{2^{\nu+1}}}; \\ \sigma\theta &\equiv \sigma_{2,0}(\theta) \pmod{\mathfrak{P}_2}, \\ &\equiv \sigma_{2,1}(\theta) \pmod{\mathfrak{P}_2^2}, \\ &\vdots \\ &\vdots \\ &\equiv \sigma_{2,\nu+1}(\theta) \pmod{\mathfrak{P}_2^{2^{\nu+1}}}. \end{aligned}$$

Before we go any further, we would like to make the following remark:

By applying the Euclidean algorithm, one can easily obtain the inverse $\hat{h}_0 = h_0(\theta)$ of $f'(\sigma_{1,0}(\theta))$ modulo \mathfrak{P}_1 . In order to find \hat{h}_1 as solution to $f'(\sigma_{11}(\theta))\hat{h}_1 \equiv 1 \pmod{\mathfrak{P}_1^2}$, we proceed as follows:

Since $\hat{h}_1 \equiv \hat{h}_0 \pmod{\mathfrak{P}_1}$, we may write the polynomial equation $\hat{h}_1 = \hat{h}_0 + pQ_2$, $Q_2 \in \mathbf{Z}[x]$, so that $f'(\sigma_{11}(\theta)) \cdot (\hat{h}_0 + p\hat{Q}_2) \equiv 1 \pmod{\mathfrak{P}_1^2}$, $\hat{Q}_2 = Q_2(\theta)$; let $f'(\sigma_{11}(\theta))\hat{h}_0 \equiv 1 + pR_2(\theta) \pmod{\mathfrak{P}_1^2}$, $R_2 \in \mathbf{Z}[x]$.

We then have

$$\begin{aligned} 1 &\equiv f'(\sigma_{11}(\theta))\hat{h}_0 + pf(\sigma_{11}(\theta))\hat{Q}_2 \\ &\equiv f'(\sigma_{11}(\theta))\hat{h}_0 + pf(\sigma_{10}(\theta))\hat{Q}_2 \pmod{\mathfrak{P}_1^2} \end{aligned}$$

and so,

$$-pR_2 \equiv pf'(\sigma_{10}(\theta))\hat{Q}_2 \pmod{\mathfrak{P}_1^2}$$

or

$$-R_2 \equiv f'(\sigma_{10}(\theta))\hat{Q}_2 \pmod{\mathfrak{P}_1}$$

or

$$-R_2\hat{h}_0 \equiv \hat{Q}_2 \pmod{\mathfrak{P}_1};$$

continuing in the same manner, we should obtain $\hat{h}_2, \dots, \hat{h}_{\nu+1}$.

Now, we are going to apply the Chinese remainder theorem to obtain our final result.

Choose the element e_0 of \mathfrak{D}_k subject to the congruences

$$e_0 \equiv 1 \pmod{\mathfrak{p}_1}, \quad e_0 \equiv 0 \pmod{\mathfrak{p}_2}$$

and let $e_1 = 3e_0^2 - 2e_0^3$; this implies that

$$e_1 \equiv 1 \pmod{\mathfrak{p}_1^2}, \quad e_1 \equiv 0 \pmod{\mathfrak{p}_2^2}.$$

Continuing with the construction we arrive at $e_{\nu+1}$ of \mathfrak{D}_k such that

$$e_{\nu+1} \equiv 1 \pmod{\mathfrak{p}_1^{2^{\nu+1}}}, \quad e_{\nu+1} \equiv 0 \pmod{\mathfrak{p}_2^{2^{\nu+1}}}.$$

For $j = 0, 1, \dots, \nu + 1$ we proceed as follows: set

$$\Sigma_j(\theta) = e_j\sigma_{1j}(\theta) + (1 - e_j)\sigma_{2j}(\theta).$$

We may write $\Sigma_j(\theta)$ as follows:

$$\Sigma_j(\theta) = (\alpha_{j0} + \beta_{j0}\omega) + (\alpha_{j1} + \beta_{j1}\omega)\theta + \dots + (\alpha_{j,n-1} + \beta_{j,n-1}\omega)\theta^{n-1},$$

where $\alpha_{ji}, \beta_{ji} \in \mathbf{Z}$, $0 \leq i \leq n - 1$ and $\mathfrak{D}_k = [1, \omega]$.

In view of the fact that $\mathfrak{D}_K/\mathfrak{D}_E \cdot \mathfrak{D}_k$ has characteristic b we write

$$\Sigma_j(\theta) = \{(\alpha_{j0}b + \beta_{j0}b\omega) + (\alpha_{j1}b + \beta_{j1}b\omega)\theta + \dots + (\alpha_{j,n-1}b + \beta_{j,n-1}b\omega)\theta^{n-1}\}/b$$

and choose α'_{ji} and β'_{ji} such that

$$\alpha'_{ji} \equiv \alpha_{ji}b \pmod{p^{2^j}}, \quad \beta'_{ji} \equiv \beta_{ji}b \pmod{p^{2^j}}$$

and $-p^{2^j}/2 < \alpha'_{ji}, \beta'_{ji} \leq p^{2^j}/2$, $0 \leq i \leq n - 1$.

Finally, we set

$$\Sigma'_j(\theta) = \{(\alpha'_{j0} + \beta'_{j0}\omega) + (\alpha'_{j1} + \beta'_{j1}\omega)\theta + \dots + (\alpha'_{j,n} + \beta'_{j,n}\omega)\theta^{n-1}\}/b.$$

The number ν should be chosen as the least nonnegative integer for which we have

$$(1a) \quad f(\Sigma'_\nu(\theta)) = 0.$$

In order to have this condition satisfied, it is necessary to have

$$(1b) \quad \Sigma'_\nu(x) \equiv \Sigma'_{\nu+1}(x) \pmod{p^{2\nu+1}}$$

though this congruence may not be sufficient. Therefore it will become necessary to test (1a) even if (1b) is established already.

From our construction one can see that $\Sigma'_\nu(\theta)$ is the action of the automorphism σ applied to θ .

II. The following questions were brought up by Professor H. Hasse. Given three equations:

$$f_H = x^5 + 10x^3 - 235x^2 + 2610x - 9353 = 0, \quad \theta_H \text{ the real root ;}$$

$$f_W = x^5 - x^3 - 2x^2 - 2x - 1 = 0, \quad \theta_W \text{ the real root ;}$$

$$f_F = x^5 - x^4 + x^3 + x^2 - 2x + 1 = 0, \quad \theta_F \text{ the real root ;}$$

$$k = \mathbf{Q}(\sqrt{-47}), \quad E = \mathbf{Q}(\theta_H), \quad K = E(\sqrt{-47}), \quad \omega = (1 + \sqrt{-47})/2,$$

K cyclic of degree 5 over k ,

$G(K/k)$ Galois group of K over k .

Questions:

(1) How to find a generating element $\sigma \in G(K/k)$?

(2) Do $\theta_H, \theta_W, \theta_F$ generate the same field? And if so, how to express them in terms of each other.

Our method given in Section I has been programmed in ALGOL for the IBM 7094 in order to solve the above question (1).

For the polynomials f_W and f_F , we have $d = -47, b = 47, p = 2$, and

$$(2) = \mathfrak{p}_1 \mathfrak{p}_2 = (2, (1 + \sqrt{-47})/2) (2, (-1 + \sqrt{-47})/2) \text{ in } k.$$

$\mathfrak{p}_1, \mathfrak{p}_2$ stay prime in K .

We obtained $\sigma\theta_W$ and $\sigma\theta_F$ at $\nu = 3$. They are as follows:

$$\begin{aligned} \sigma\theta_W &= \{(54 - 14\omega) + (58 - 22\omega)\theta_W \\ &\quad + (55 - 16\omega)\theta_W^2 + (30 - 13\omega)\theta_W^3 + (-56 + 18\omega)\theta_W^4\}/47 \\ \sigma\theta_F &= \{(68 + 5\omega) + (-72 + 3\omega)\theta_F + (-21 - 5\omega)\theta_F^2 \\ &\quad + (22 + 3\omega)\theta_F^3 + (-44 - 6\omega)\theta_F^4\}/47. \end{aligned}$$

The procedure used to solve the second question is even simpler: in order to express θ_H , say, in terms of θ_W , we only have to begin with finding a polynomial $g_0(\theta_W)$ with coefficients in $\mathbf{Z}/2$ of degree less than 5 such that

$$\theta_H \equiv g_0(\theta_W) \pmod{2}.$$

In our cases we have

$$\begin{aligned} \theta_H &\equiv \theta_W^2 + \theta_W \pmod{2}, \\ \theta_W &\equiv \theta_F^4 + 1 \pmod{2}. \end{aligned}$$

Proceed from here by the same method given in Section I until we arrive at a polynomial $g_\mu(x)$ such that $\theta_H = g_\mu(\theta_W) \bmod 2^{2^\mu}$ and $f_H(g_\mu(\theta_W)) = 0$. Again, a bound for μ was given in [1].

We obtain the following results from our ALGOL program:

$$\begin{aligned}\theta_H &= 5\theta_W^2 - 5\theta_W - 2, \\ \theta_W &= -\theta_F^4 - 2\theta_F + 1.\end{aligned}$$
