Irregular Prime Divisors of the Bernoulli Numbers

By Wells Johnson

Abstract. If p is an irregular prime, $p < 8000$, then the indices $2n$ for which the Bernoulli quotients $B_{2n}/2n$ are divisible by p^2 are completely characterized. In particular, it is always true that $2n > p$ and that $B_{2n}/2n \not\equiv (B_{2n+p-1}/2n + p - 1) \pmod{p^2}$ if $(p, 2n)$ is an irregular pair. As a result, we obtain another verification that the cyclotomic invariants μ_p of Iwasawa all vanish for primes $p < 8000$.

1. Introduction and Summary. Let B_n denote the sequence of Bernoulli numbers in the "even-index" notation of [1]. If $B_{2n} = P_{2n}/Q_{2n}$ with $(P_{2n}, Q_{2n}) = 1$, then the prime factorization of the denominator Q_{2n} is given precisely by the von Staudt-Clausen theorem. The prime divisors of P_{2n}, however, are more difficult to obtain. Their importance stems from the fact that, more than a century ago, Kummer proved that the Fermat equation $x^p + y^p = z^p$ has no integral solutions if p is a regular prime, that is, one for which p does not divide $P_2P_4P_6 \cdots P_{p-3}$.

A rather old result, now commonly known as J. C. Adams' theorem (cf. [10, p. 261]), states that if p is a prime not dividing Q_{2n} and p^e divides n for some $e \geqq 1$, then p^e also divides P_{2n}. Thus, given any prime power p^e for $p > 3$, $e \geqq 1$, there exist infinitely many Bernoulli numerators P_{2n} which are divisible by p^e. If we add the restriction that $(p, n) = 1$, however, then the problem of determining when p^e divides P_{2n} becomes more difficult. It turns out to be convenient to study the quotients $B_{2n}/2n = P_{2n}/2nQ_{2n}$, which, when reduced, are p-integers if $p - 1 \nmid 2n$ by the theorems of von Staudt-Clausen and J. C. Adams.

The general problem, then, is to determine, for a given prime-power p^e, those indices, $2n$, $p - 1 \nmid 2n$, for which p^e divides the p-integer $B_{2n}/2n$. It follows immediately from a congruence of Kummer that p must be irregular, and that p divides $B_{2n}/2n$ if and only if p divides $P_{2n'}$, where $2n'$ is the least positive residue of $2n \pmod{p - 1}$. This settles the case $e = 1$. Moreover, we see that any irregular prime p divides infinitely many Bernoulli numerators P_{2n} with $(p, n) = 1$.

This paper reports on some computations done recently on the PDP-10 computer at Bowdoin College to investigate the case $e = 2$. About fifty years ago, Pollaczek [9] noted that 37^2 divides $B_{284}/284$, showing that the case $e = 2$ is possible. Montgomery [8] raised the question whether or not p^2 divides P_{2n} for $0 < 2n < p - 1$. Our computations show that the answer to this is negative for all irregular primes $p < 8000$. Further, for the irregular primes $p < 8000$, we can characterize precisely those indices $2n$ for which p^2 divides $B_{2n}/2n$. Our results show that the *square* of any irregular prime $p < 8000$ divides infinitely many Bernoulli numerators P_{2n} with $(p, n) = 1$. Finally, we compare some of our computations to those done earlier

by Pollaczek [9] and discuss the important relationship of these results to the determination of the cyclotomic invariants μ_p of Iwasawa.

If p is an irregular prime and p divides P_{2n} for $0 < 2n < p - 1$, then we shall refer to $(p, 2n)$ as an *irregular pair*. For a given irregular prime p, the number of such irregular pairs is called the *index of irregularity of p*.

2. The Congruences of Kummer. We state the fundamental congruences of Kummer (cf. [10, p. 266]), valid for $2 \leqq r + 1 \leqq 2n$ and primes p for which $p - 1 \nmid 2n$:

$$\sum_{s=0}^{r} (-1)^s \binom{r}{s} \frac{B_{2n+s(p-1)}}{2n + s(p-1)} \equiv 0 \pmod{p^r}.$$

For $r = 1, 2$ we obtain for $p - 1 \nmid 2n$:

$$\frac{B_{2n}}{2n} \equiv \frac{B_{2n+(p-1)}}{2n + (p-1)} \pmod{p}, \qquad n \geqq 1, \tag{1}$$

$$\frac{B_{2n}}{2n} - 2\frac{B_{2n+(p-1)}}{2n + (p-1)} + \frac{B_{2n+2(p-1)}}{2n + 2(p-1)} \equiv 0 \pmod{p^2}, \qquad n \geqq 2. \tag{2}$$

An analysis of (1) gives the results stated in the previous section for the case $e = 1$ of the general problem. We remark that the argument used here is essential for all known proofs of the existence of infinitely many irregular primes in certain arithmetic progressions (cf. [11], [2], [8], and [7]).

For the case $e = 2$, we use Eq. (2). If p^2 divides $B_{2n}/2n$, then as above, $(p, 2n')$ must be an irregular pair, where $2n'$ is the least positive residue of $2n \pmod{p-1}$. Also, given an irregular pair, $(p, 2n')$, we define $A_t = B_{2n'+t(p-1)}/2n' + t(p-1)$ for $t \geqq 0$. By (1), $A_t \equiv 0 \pmod{p}$, so that we may define a_t by the conditions $A_t \equiv a_t p \pmod{p^2}$, $0 \leqq a_t < p$. Hence p^2 divides A_t if and only if $a_t = 0$. Since $B_2 = \frac{1}{6}$, it follows that $n' > 1$. Equation (2) then implies that

$$a_{t+2} - a_{t+1} \equiv a_{t+1} - a_t \pmod{p}, \qquad t \geqq 0,$$

which gives

$$a_t - a_0 \equiv t(a_1 - a_0) \pmod{p}, \qquad t \geqq 1.$$

Thus p^2 divides $B_{2n}/2n$ if and only if $2n = 2n' + t(p-1)$, where $(p, 2n')$ is an irregular pair, and where $t \geqq 0$ and t satisfies the congruence

$$-a_0 \equiv t(a_1 - a_0) \pmod{p}. \tag{3}$$

Given an irregular pair $(p, 2n')$, if it happens that $a_1 = a_0$, then $a_t = a_0$ for all $t \geqq 1$. If $a_0 \neq 0$, then p^2 divides no $B_{2n}/2n$ with $2n \equiv 2n' \pmod{p-1}$, but if $a_0 = 0$, then p^2 divides every $B_{2n}/2n$ with $2n \equiv 2n' \pmod{p-1}$. If $a_1 \neq a_0$, however, then we can solve (3) for t uniquely $\pmod{p}$. In this case, then, every interval of length $p^2 - p$ contains exactly one index $2n$, $2n \equiv 2n' \pmod{p-1}$, for which p^2 divides $B_{2n}/2n$. The index $2n$ is divisible by p only when $t \equiv 2n' \pmod{p}$. Thus p^2 divides infinitely many Bernoulli numerators P_{2n} with $(p, n) = 1$ if and only if, for some irregular pair $(p, 2n')$, either (a) $a_0 = a_1 = 0$ or (b) $a_0 \neq a_1$ and the unique solution $t \pmod{p}$ to (3) is not $2n'$.

3. Computational Results. The values of a_0 and a_1 were computed for each of the 502 irregular pairs $(p, 2n)$, $p < 8000$, previously reported by the author [5]. For all 502 pairs, it was found that $a_0 \not\equiv 0$, and that $a_1 \not\equiv a_0$ so that it was possible to solve (3) for $t \pmod p$. For no pair $(p, 2n)$ did we ever obtain $t = 2n$. We thus have the following:

THEOREM. *If p is an irregular prime, $p < 8000$, then*

(A) *p^2 does not divide any of the Bernoulli numerators $P_2, P_4, P_6, \cdots, P_{p-3}$.*

(B) *$B_{2n}/2n \not\equiv (B_{2n+(p-1)}/2n + (p-1)) \pmod{p^2}$ for all irregular pairs $(p, 2n)$.*

(C) *Every interval of length $p^2 - p$ contains exactly i_p indices $2n$ with $B_{2n}/2n \equiv 0 \pmod{p^2}$, where i_p is the index of irregularity of p. Moreover, for all of these, $(p, n) = 1$, so that there exist infinitely many Bernoulli numerators P_{2n}, $(p, n) = 1$, divisible by p^2.*

For each irregular pair $(p, 2n)$, the values of a_0 and a_1 were computed from the following equations of E. Lehmer [6], valid for $p > 5$, $p - 1 \nmid 2s - 2$:

$$(4) \quad \sum_{r=1}^{[p/6]} (p - 6r)^{2s-1} \equiv (c_{2s}B_{2s}/4s) \pmod{p^2}, \qquad c_{2s} = 6^{2s-1} + 3^{2s-1} + 2^{2s-1} - 1,$$

$$(5) \quad \sum_{r=1}^{[p/4]} (p - 4r)^{2s-1} \equiv (d_{2s}B_{2s}/4s) \pmod{p^2}, \qquad d_{2s} = (2^{2s} - 1)(2^{2s-1} + 1).$$

For each irregular pair $(p, 2n)$, we first tested for the invertibility of $c_{2n} \pmod p$. For $c_{2n} \not\equiv 0 \pmod p$, we next computed the sum $\pmod{p^2}$ in (4) with $2s = 2n$, writing it in the form $e + fp$, $0 \leqq e, f < p$. It was first checked that $e = 0$, again verifying that indeed $(p, 2n)$ is an irregular pair. Then a_0 was computed from the congruence $a_0 \equiv 2c_{2n}^{-1}f \pmod p$. The value of a_1 was found similarly, using (4) with $2s = 2n + p - 1$. For only one irregular pair, (1201, 676), did c_{2n} fail to be invertible. For this pair, $d_{2n} \not\equiv 0 \pmod p$, so that we were able to compute the values of a_0 and a_1 from Eq. (5). After computing $t \pmod p$ from (3), we performed a final check by showing that the sum in (4) or (5) vanishes $\pmod{p^2}$ for $2s = 2n + t(p - 1)$. A partial table of our results is included at the end of this paper.

4. Pollaczek's Results and the Cyclotomic Invariants μ_p of Iwasawa. Pollaczek [9, p. 31] performed these computations some time ago for the three irregular primes $p < 100$. He computed $(-B_{2n}/n)$ rather than $(B_{2n}/2n) \pmod{p^2}$, so that our values of a_0 and a_1 must be multiplied by -2 in order to make valid comparisons. The results agree for $p = 37$ and also for $p = 59$ after a transposition of Pollaczek's indices to correct his obvious inconsistency. For $p = 67$, there seems to be an error in Pollaczek's value of B_{62}', corresponding to our value of a_1. A direct computation of Eq. (4) negates his claim that 67^2 divides P_{190}.

Iwasawa [3, p. 782] has shown that the cyclotomic invariant μ_p, important in the theory of class numbers of cyclotomic fields, vanishes if p is either a regular prime or an irregular prime for which $a_0 \not\equiv a_1$ for all irregular pairs $(p, 2n)$. Iwasawa invoked the computations of Pollaczek to conclude that $\mu_p = 0$ for all primes $p < 100$. More recently, using other tests, Iwasawa and Sims [4] and the author [5] have shown that $\mu_p = 0$ for all primes $p < 8000$. The computations reported here give another verification that this is true.
