

## The Comparison of Numerical Methods for Solving Polynomial Equations

By Aurél Galántai

**Abstract.** In this paper we compare the Turán process [5]–[6] with the Lehmer-Schur method [2]. We prove that the latter is better.

**1. The Algorithms.** We first describe the Turán process [5]–[6] which can be considered as an improvement of Graeffe's method. For the complex polynomial

$$(1.1) \quad p_0(z) \equiv \sum_{j=0}^n a_{j0} z^j = 0 \quad (a_{j0} \in \mathbb{C}, a_{00} a_{n0} \neq 0),$$

the method can be formulated as follows.

Let

$$(1.2) \quad p_j(z) \equiv p_{j-1}(\sqrt{z}) p_{j-1}(-\sqrt{z}) \equiv \sum_{k=0}^n a_{kj} z^k \quad (j = 1, 2, \dots)$$

be the  $j$ th Graeffe transformation and let

$$(1.3) \quad M[p_0(z), m_0] = \left[ \max_{1 \leq k \leq n} \left| \frac{\sigma_k}{n} \right|^{\mu_0/k} \right]^{-1},$$

where  $\mu_0 = 2^{-m_0}$ ,  $\sigma_0 = 0$ ,

$$(1.4) \quad \sigma_k = \left[ k a_{k m_0} - \sum_{j=1}^{k-1} a_{j m_0} \sigma_{k-j} \right] / a_{0 m_0} \quad (k = 1, \dots, n)$$

and  $m_0 \geq 1$  is fixed.

Let the constants  $\alpha_{m_0}, l$  be defined by the inequalities

$$0.5 < \alpha_{m_0} < 5^{-\mu_0}, \quad l > \pi \left[ \arccos \frac{2.5 + \alpha_{m_0}}{2 + 2\alpha_{m_0}} \right]^{-1} - 1, \quad m_0 \geq 2.$$

Then with the notations

$$(1.5) \quad M^{(0)} = M[p_0(z), m_0], \quad S^{(0)} = 0,$$

the  $d$ th step of the algorithm is the following:

1. *Algorithm (T).* (i) Let

$$S_j^{(d+1)} = S_j^{(d)} + 0.5(1 + \alpha_{m_0}) M^{(d)} \exp\left(j \frac{2\pi i}{l+1}\right),$$

where  $j = 0, 1, \dots, l$  and  $i = \sqrt{-1}$ .

(ii) If there exists an index  $j$  such that  $p_0(S_j^{(d+1)}) = 0$ , then we get a root and the process terminates.

(iii) Let us compute the quantities

$$M_j^{(d+1)} = M[p_0(z + S_j^{(d+1)}), m_0] \quad (j = 0, 1, \dots, l)$$

and let

$$M^{(d+1)} = \min_j M_j^{(d+1)} = M_{j^{(d)}}^{(d+1)}, \quad S^{(d+1)} = S_{j^{(d)}}^{(d+1)}.$$

Turán [5] proved that  $S^{(d)}$  tends to a root of  $p_0(z)$ , and the convergence is linear. Turán [5] also proved that the number of iterations needed to achieve an arbitrary relative error  $\epsilon (> 0)$  is independent of  $p_0(z)$  and depends on degree  $p_0(z)$  only.

Our purpose is to answer the remarks of the last section of [6]. For this reason we compare the Turán process with the Lehmer-Schur method which is often applied in practice ([2], [3], [4]). This algorithm can be described as follows.

Let

$$(1.6) \quad T[p_0(z)] = \sum_{j=0}^{n-1} (\bar{a}_{00}a_{j0} - a_{n0}\bar{a}_{n-j,0})z^j$$

and

$$(1.7) \quad T^j[p_0(z)] = T\{T^{j-1}[p_0(z)]\} \quad (j = 2, \dots).$$

Let us compute the numbers  $c_j = T^j[p_0(0)]$ , ( $j = 1, \dots, k$ ), where

$$(1.8) \quad k = \min\{m \in \mathbf{N} | c_m = 0\}.$$

Here,  $\mathbf{N}$  denotes the set of nonnegative integers. With the aid of the sequence  $\{c_j\}_{j=1}^k$  we define the function  $N[p_0(z)]$  as follows

$$N[p_0(z)] = \begin{cases} 1 & \text{if } \exists j \in \{1, \dots, k-1\} \text{ such that } c_j < 0, \\ 0 & \text{if } c_j > 0 \text{ (} j = 1, \dots, k-1 \text{) and degree } T^{k-1}[p_0(z)] = 0, \\ -1 & \text{otherwise.} \end{cases}$$

Lehmer [2] proved that if  $N[p_0(z)] = 1$  then the polynomial  $p_0(z)$  has a root in  $\{z \in \mathbf{C} | |z| \leq 1\}$ , if  $N[p_0(z)] = 0$  then  $p_0(z)$  has no roots in this set. We shall return to the case  $N[p_0(z)] = -1$ .

Let us introduce the notations

$$(1.9) \quad \alpha_j^{(d)} = \begin{cases} 0.5\gamma_0^{(d)}R^{(d-1)} & (j = 0), \\ 0.4\gamma_j^{(d)}R^{(d-1)} & (j = 1, \dots, 8), \end{cases}$$

and

$$(1.10) \quad \beta_j^{(d)} = \begin{cases} z^{(d-1)} & (j = 0), \\ z^{(d-1)} + \frac{0.75R^{(d-1)}}{\cos \frac{\pi}{8}} \exp\left(\frac{2\pi i(j-1)}{8}\right) & (j = 1, \dots, 8), \end{cases}$$

where the sequences  $\{R^{(d)}\}$ ,  $\{z^{(d)}\}$  and  $\{\gamma_j^{(d)}\}$  are defined by the  $d$ th step of the Lehmer-Schur method ( $d = 1, \dots$ ). Let  $\tilde{p}_0(z) = p_0(z)/\psi$  ( $\psi > 0$ ) and

$$(1.11) \quad z^{(0)} = 0; \quad R^{(0)} = 1 + \max_j \left| \frac{a_{j0}}{a_{n0}} \right|.$$

Then the  $d$ th step can be written as follows.

2. *Algorithm (L).* (i) If there exists an index  $j$  such that  $p_0(\beta_j^{(d)}) = 0$ , then we get a root and the process terminates.

(ii) We choose the index  $j \in \{0, 1, \dots, 8\}$  such that

$$N[\tilde{p}_0(\alpha_j^{(d)}z + \beta_j^{(d)})] = 1$$

and let

$$z^{(d)} = \beta_j^{(d)}, \quad R^{(d)} = \alpha_j^{(d)}.$$

The numbers  $\gamma_j^{(d)} \in [1, 1 + \delta]$ , ( $\delta \leq 0.5$ ) are chosen such that  $N[\tilde{p}_0(\alpha_j^{(d)}z + \beta_j^{(d)})] \geq 0$  will be satisfied (except in unusual circumstances  $\gamma_j^{(d)} = 1$  can be chosen). Lehmer [2] proved that process converges linearly. The number of iteration steps needed to achieve an arbitrary absolute error  $\epsilon$  ( $> 0$ ) depends on  $p_0(z)$ .

2. **The Limitations of the Algorithms.** Denote by  $\mathbf{Z}$  the set of integers and let  $\mathbf{P}_n$  be the set of complex polynomials of degree  $n$ .

A numerical method  $M$  (iterative process) for solving  $p_0(z) = 0$  where  $p_0(z) \in \mathbf{P}_n$  can be identified with the sequence  $\{b_k\} \subset \mathbf{C}$  which rises from the computation. This sequence depends on  $p_0(z)$  and will be denoted by  $\{Mp_0\} = \{b_k\}$ . There exists a subsequence  $\{b_{k_j}\}$  of  $\{b_k\}$  such that

$$(2.1) \quad z^* = \lim_{j \rightarrow \infty} b_{k_j} \quad \text{and} \quad p_0(z^*) = 0.$$

A digital computer can perform elementary (complex) operations only over the finite set

$$(2.2) \quad S[0, K] \cap \mathbf{C}_\delta,$$

where  $S[0, K] = \{z \in \mathbf{C} \mid |z| \leq K\}$  and

$$(2.3) \quad \mathbf{C}_\delta = \{z \in \mathbf{C} \mid z = k\delta + j\delta i: k, j \in \mathbf{Z}\} \quad (\delta > 0).$$

If there exists an element  $b_{k_0}$  in the sequence  $\{b_k\}$  such that  $|b_{k_0}| > K$ , then the algorithm  $M$  cannot continue to run because of overflow.

In order to study the overflow we introduce the class of polynomials

$$(2.4) \quad \mathbf{P}_M(a, K, K^*) = \{p_0(z) \in \mathbf{P}(a, K^*) \mid \{Mp_0\} \subset S[0, K], |\{Mp_0\}| = \infty\},$$

where

$$(2.5) \quad \mathbf{P}(a, K^*) = \{p_0(z) \in \mathbf{P}_n \mid 0 < |z_j| \leq a \ (j = 1, \dots, n), \|p_0(z)\| \leq K^*\}$$

and

$$(2.6) \quad \|p_0(z)\| = \max_j |a_{j_0}|.$$

Here  $|\{Mp_0\}|$  denotes the cardinality of  $\{b_k\}$ , and  $z_j$  is the  $j$ th zero of  $p_0(z)$ .

The set  $P_M(a, K, K^*)$  represents the class of all polynomials which can be solved by  $M$  in a bounded set.

The following statements are valid.

**THEOREM 2.1.** *The set  $P_T(a, K, K^*)$  defined by Algorithm 1 is empty for every  $a, K, K^* > 0$ .*

*Proof.* If the roots of  $p_0(z)$  are arranged so that

$$(2.7) \quad |z_1| \geq |z_2| \geq \dots \geq |z_n|,$$

then the estimate

$$(2.8) \quad 5^{-\mu_0} \leq \frac{|z_n|}{M[p_0(z), m_0]} \leq 1$$

is valid (see [5]–[6]). For this reason the convergence of Algorithm 1 is identical with

$$(2.9) \quad |z_n^{(d)}| \leq cq^d \quad (c > 0, 0 < q < 1),$$

where  $z_n^{(d)}$  is the zero of  $p_0(z + S^{(d)})$ , ( $d = 0, 1, \dots$ ) of minimal absolute value. Using the inequality (2.8), we have

$$(2.10) \quad \frac{n}{5c'} \left(\frac{1}{q}\right)^{d/\mu_0} \leq \frac{n}{5|z_n^{(d)}|^{1/\mu_0}} \leq |\sigma_{k(d)}^{(d)}| \quad (d \geq d')$$

where  $k(d) \in \{1, \dots, n\}$  is the index of the maximal element in (1.3) and

$$(2.11) \quad \frac{n}{5c'} \left(\frac{1}{q}\right)^{d'/\mu_0} > 1.$$

Since  $|\sigma_{k(d)}^{(d)}| = O(w^d)$ , where  $w = (1/q)^{1/\mu_0}$ , therefore for a large index  $d_0$

$$(2.12) \quad |\sigma_{k(d)}^{(d)}| > K \quad (d \geq d_0)$$

is satisfied. Thus the theorem is proved.

**THEOREM 2.2.** *If  $K \geq K^*2^{n+1}(1 + a^n2^n)^{n+1} + 1$ , then*

$$(2.13) \quad P_L(a, K, K^*) = P(a, K^*)$$

*is satisfied for Algorithm 2.*

*Proof.* It is easy to see that the quantities recurring in the algorithm satisfy the inequalities

$$(2.14) \quad |p_0(\beta_j^{(d)})| \leq \begin{cases} \|p_0\|2^{n+1} & (a < 0.5), \\ \|p_0\|(1 + 2^n a^n)^{n+1} & (a \geq 0.5), \end{cases}$$

$$(2.15) \quad \|T^j[p_0(z)]\| \leq \frac{1}{2}(2\|p_0(z)\|)^{2^j} \quad (j = 1, \dots, n)$$

and

$$(2.16) \quad \|p_0(\alpha_j^{(d)}z + \beta_j^{(d)})\| \leq \|p_0(z)\|(2 + 2^{n+1}a^n)^n \quad (j = 0, 1, \dots, 8),$$

for  $d = 0, 1, \dots$ . With the notation

$$\delta = \|p_0(z)\|(2 + 2^{n+1}a^n)^n,$$

and by using (2.15)–(2.16), we have

$$(2.17) \quad \|T^k[p_0(\alpha_j^{(d)}z + \beta_j^{(d)})]\| \leq \frac{1}{2}(2\delta)^{2^k} \quad (k = 1, \dots, n).$$

Since  $K$  is greater than the right side of (2.14) and (2.16), using  $\psi > 2\delta$  we can get  $\tilde{\delta} < 0.5$  which proves the theorem.

The difference between Algorithms 1 and 2 is caused by the fact that Algorithm 1 is based on the inequality (2.8) while Algorithm 2 is based on the characteristic function  $N[p_0(z)]$  which is invariant for the mapping  $p_0(z) \rightarrow p_0(z)/\psi, (\psi > 0)$ .

We remark that Algorithm 1 modified by the mappings

$$p_0(z) \rightarrow p_0(z)/\psi, \quad p_0(z) \rightarrow p_0(z/\psi) \quad (0 < \psi \leq K)$$

also has a  $P_T(a, K, K^*)$  empty for every  $a, K, K^* > 0$ .

**3. The Study of Cost Functions.** In the previous section it was proved that Algorithm 1 is unapplicable. Since an approximate solution with a given error  $\epsilon > 0$  can be computed in the bounded set  $S[0, \tilde{K}]$ , where  $\tilde{K}$  depends on  $p_0(z), \epsilon$ , and the method  $M$ , further analysis of the algorithms is necessary.

The cost function of the  $j$ th algorithm ( $j = 1, 2$ ) is defined by the number of additions and multiplications per step and denoted by  $K_a^j$  and  $K_m^j$ .

Assuming that the computing time of the  $k$ th root can be characterized by three additions and three multiplications (which is a rough underestimate), the cost function of Algorithm 1 is

$$(3.1) \quad K_m^1 = (l + 1)(m_0 + 4)\frac{n^2}{2} + (l + 1)(m_0 + 8)\frac{n}{4} + O(1),$$

$$(3.2) \quad K_a^2 = (l + 1)(m_0 + 4)\frac{n^2}{4} + (2l + 3)n + O(1).$$

For the cost function of Algorithm 2 the inequalities

$$(3.3) \quad K_m^2 \leq 27n^2 - 18n,$$

$$(3.4) \quad K_a^2 \leq 9n^2 + 36n,$$

hold.

If we identify the bounds (3.3)–(3.4) with the cost of one step, then the speed of Algorithm 2 is

$$(3.5) \quad |z^{(d)} - z^*| \leq c_2(2/5)^d \quad (d = 0, 1, \dots).$$

The speed of Algorithm 1 is

$$(3.6) \quad |S^{(d)} - z^*| \leq c_1 [q(\alpha_{m_0}, m_0, l)]^d \quad (d = 0, 1, \dots),$$

where

$$(3.7) \quad q(\alpha_{m_0}, m_0, l) = \left[ 1 + 0.25(1 + \alpha_{m_0})^2 - (1 + \alpha_{m_0}) \cos \frac{\pi}{l+1} \right]^{1/2} \alpha_{m_0}^{-1}.$$

If  $\delta = (m_0 + 4)(l + 1)/54 > 1$  and  $n \geq n'$ , then

$$(3.8) \quad K_m^1 \geq \delta K_m^2 \quad \text{and} \quad K_a^1 > \delta K_a^2.$$

**THEOREM 3.1.** *If  $l \geq l'$ , then*

$$(3.9) \quad q(\alpha_{m_0}, m_0, l) > (2/5)^\delta.$$

*Proof.* For a large  $l'$

$$(3.10) \quad q(\alpha_{m_0}, m_0, l)^2 \geq \frac{1 - (\cos \pi/(l+1))^2}{\alpha_{m_0}^2} > \frac{9\alpha_{m_0}^{-2}}{(l+1)^2} \quad (l \geq l')$$

and

$$(3.11) \quad (5/2)^\delta > l + 1.$$

From this fact the theorem immediately follows.

If  $l \geq l'$ , then the cost of  $d$  steps of Algorithm 1 gives  $[\delta d]$  steps using the Lehmer-Schur method. By Theorem 3.1 we have

$$(3.12) \quad c^* [q(\alpha_{m_0}, m_0, l)]^d > (2/5)^{[\delta d]} \quad (c^* > 0, d \geq d_0),$$

which proves that *the Lehmer-Schur process is faster than the Turán process*. For the parameters  $m_0 = 4$ ,  $\alpha_4 = 0.9$ ,  $l = 11$ , (see [5]–[6]) the relation (3.12) is also satisfied. This can be verified easily by (3.10) and (3.11).

In the paper [6] there is a reference to the infinite precision integer arithmetics [1] for the sake of application of Algorithm 1. It is known [1] that the computing time of the multiplication is at most

$$(3.13) \quad l(x)^{1+\tau} \quad (1 \geq \tau > 0)$$

units of time ( $l(x)$  denotes the length of  $x$  in the binary system). Since Algorithm 1 has to use numbers of length at least  $2^m 0^{-2} l(x)$  where  $l(x)$  is needed by Algorithm 2, for the cost functions in the measure of computing time,

$$(3.14) \quad K_m^1(t) \geq (\delta 2^m 0^{-2})^{1+\tau} K_m^2(t)$$

is satisfied. As a simple corollary, in (3.12) we can write  $\delta 2^m 0^{-2}$  instead of  $\delta$ . This fact increases the relative convergence speed of the Lehmer-Schur process.
