IMPROVED CONVERGENCE RATES FOR INTERMEDIATE PROBLEMS

CHRISTOPHER BEATTIE AND W. M. GREENLEE

ABSTRACT. Improved convergence rate estimates are derived for a variant of Aronszajn-type intermediate problems that is both computationally feasible and convergent for problems with nontrivial essential spectra. In a previous paper the authors obtained rate of convergence estimates for this method in terms of containment gaps between subspaces. In the present work, techniques for estimating relatively unbounded perturbations are refined in order to apply the Kato-Temple inequalities. This yields convergence rates for the intermediate operator eigenvalues in terms of squares of containment gaps between subspaces. Convergence rate estimates are also obtained for the intermediate problem eigenvectors, and comparisons are made with previously known results for the method of special choice.

1. Introduction

The method of intermediate problems of Weinstein and Aronszajn (cf. [33]) provides a systematic method for generating improvable bounds for eigenvalues of selfadjoint operators which are complementary to the Rayleigh-Ritz bounds. Convergence criteria for Weinstein's method date back to Aronszajn and Weinstein [2, 3] for problems with compact resolvent, and for Aronszajn's method to Aronszajn [1] and Bazley and Fox [5] for problems with compact resolvent and relatively bounded perturbations. The approximation method of Weinberger [30, 32], which is closely related to the method of intermediate problems (cf. [16]), is the first method for which convergence criteria were given in settings admitting a nontrivial essential spectrum. For intermediate problem applications that admit nontrivial essential spectra and perturbations that are not relatively bounded—as occur, e.g., in many quantum mechanical eigenvalue problems—convergence results are relatively recent, including those of Beattie [9], Beattie and Greenlee [10], Brown [13, 14], and Greenlee [19].

Convergence rates for eigenvalues of intermediate problems were first derived by Weinberger [29] for Weinstein's method. Subsequently, Fix [15] and Birkhoff...
and Fix [12] obtained convergence rates for Bazley's method of special choice [4] in the case of bounded perturbations, and Poznyak [25, 26] derived rate of convergence results for variants of Aronszajn's method with relatively bounded perturbations of the base operator. These results on convergence rates all depend on compactness in some fashion. Even less is known about convergence rates for eigenprojections and eigenvectors. Estimates such as those found in Kato [22], Weinberger [31], and Bazley and Fox [6], depend on both upper and lower bound information, while in [12, 15] convergence rates for the method of special choice have been obtained in the case of bounded perturbations.

Herein we refine the rate of convergence estimates of our recent paper [11] for a particular method of Aronszajn type known variously as “truncation including the remainder” [9, 10], or as “Aronszajn’s method with a truncated base problem” [19]. This method was first discussed by Bazley and Fox [8] who verified two interesting features of the method. First, with an appropriate selection of trial vectors, this method dominates Weinberger's method and, secondly, this method is always dominated by Aronszajn’s method without truncation. Thus, we simultaneously obtain convergence rates for other variants of Aronszajn’s method as well. Truncation including the remainder is the only method of Aronszajn type known to be both computationally feasible and convergent for problems with nontrivial essential spectra. This method also requires relatively unbounded perturbations of the base operator whenever the operator of interest is itself unbounded, and, like Weinberger’s method, can be employed for constraint problems (cf. [19]).

In §2 we formulate Aronszajn’s method with a truncated base operator, and review previous results on convergence that are relevant to the sequel. The theorems of §3 depend on an estimate of Kato [22]. Theorem 3.1 effectively squares the rate of convergence estimate for eigenvalues obtained in [11]. Both of these estimates depend strongly on implementation of a construction of [19] to estimate relatively unbounded perturbations by means of abstractly defined bounded perturbations. While this device enables one to estimate relatively unbounded perturbations, it does not immediately yield convergence information for the eigenvectors actually constructed in the approximation method, contrary to a remark in [19]. Then, in Theorem 3.2, we derive estimates for eigenprojections and eigenvectors. While these estimates may be somewhat crude, they appear to be the first that are applicable in the presence of nontrivial essential spectra and relatively unbounded perturbations without prior upper bound information. Finally, in §4 we extend the technique of [11] for implementing the convergence rate estimates in differential eigenvalue problems so as to apply Theorems 3.1 and 3.2. For illustration we directly compare rates of convergence obtained from our theorems with rates derived in [12, 15] for approximation of Sturm-Liouville problems by the method of special choice, and provide two computational examples that illustrate the derived rates.

2. The approximation method

Let \( \mathcal{H} \) be a separable complex Hilbert space with norm \( \|u\| \) and inner product \( \langle u, v \rangle \). Let \( A \) be a selfadjoint operator with domain \( \mathcal{D}(A) \) dense in \( \mathcal{H} \). We suppose that \( A \) is bounded below with spectrum that begins with isolated eigenvalues of finite multiplicity,
\[ \lambda_1(A) \leq \lambda_2(A) \leq \cdots \leq \lambda_\infty(A), \]

and corresponding orthonormal eigenvectors \( u_1, u_2, \ldots \). Here, \( \lambda_\infty(A) \) denotes the least point of the essential spectrum of \( A \), where by convention we set \( \lambda_\infty(A) = \infty \) if the essential spectrum of \( A \) is empty. The closure of the quadratic form \( \langle Au, u \rangle \) is denoted by \( a(u) \).

To apply the method of intermediate problems, we require knowledge of another closed quadratic form \( a_0(u) \), satisfying \( a_0(u) \leq a(u) \) for all \( u \in \mathcal{D}(a) \). Furthermore, we require that the spectral problem for the self-adjoint operator \( A_0 \) corresponding to \( a_0 \) is solved explicitly, and that the spectrum of \( A_0 \) also begins with isolated eigenvalues of finite multiplicity,

\[ \lambda_1(A_0) \leq \lambda_2(A_0) \leq \cdots \leq \lambda_\infty(A_0), \]

with corresponding orthonormal eigenvectors \( u_0^0, u_0^1, \ldots \). The second monotonicity principle implies that \( \lambda_\infty(A_0) \leq \lambda_\infty(A) \), and that for each \( i \) such that \( \lambda_i(A) < \lambda_\infty(A_0) \), \( \lambda_i(A_0) \) exists and \( \lambda_i(A_0) \leq \lambda_i(A) \). Without loss of generality we may assume that the difference between \( a \) and \( a_0 \) is strictly positive, i.e.,

\[ \hat{a}(u) = a(u) - a_0(u) \geq \alpha \|u\|^2, \]

for some \( \alpha > 0 \) and all \( u \in \mathcal{D}(a) \).

Now pick a real number \( \gamma \) satisfying \( \lambda_1(A_0) < \gamma \leq \lambda_\infty(A_0) \), with the restriction that \( \gamma < \lambda_\infty(A_0) \) if \( A_0 \) has an infinity of eigenvalues below \( \lambda_\infty(A_0) \). Define the truncation of \( A_0 \) at \( \gamma \) by

\[ A_0^{(\gamma)} = A_0 E_\gamma - [A_0] + \gamma (I - E_\gamma - [A_0]), \]

where \( E_\gamma[A_0] \) is the right-continuous resolution of the identity for \( A_0 \). Observe that \( A_0^{(\gamma)} \) has the same action as \( A_0 \) on the finite-dimensional subspace

\[ \mathcal{U}_0^\gamma = \mathcal{R}(E_\gamma - [A_0]) = E_\gamma - [A_0] \cdot \mathcal{H}, \]

and acts as scalar multiplication by \( \gamma \) on vectors in \( (\mathcal{U}_0^\gamma)^\perp \). The corresponding quadratic form \( a_0^{(\gamma)} \) may be used to define a second positive form,

\[ \hat{a}(u) = a(u) - a_0^{(\gamma)}(u) \geq \hat{a}(u) \geq \alpha \|u\|^2. \]

Obviously, \( \mathcal{D}(\hat{a}) = \mathcal{D}(a) \), \( \hat{a} \) is a closed quadratic form, and the corresponding selfadjoint operator is given by \( \tilde{A} = A - A_0^{(\gamma)} \) on \( \mathcal{D}(A) = \mathcal{D}(A) \).

The method of approximation to be studied is simply Aronszajn’s method with the truncated base operator \( A_0^{(\gamma)} \) instead of the original base operator \( A_0 \) (cf. [18, 19]). The method proceeds by selecting a set of trial vectors \( \{p_i\}_{i=1}^\infty \subset \mathcal{D}(\tilde{A}) \) and defining for each \( n \)

\[ (2.1) \quad P_n u = \sum_{i,j=1}^n \langle u, \tilde{A}p_i \rangle b_{ij} p_j , \]

where \( [b_{ij}] \) is the matrix inverse to \( [(p_i, \tilde{A}p_j)]_{i,j=1}^n \). Then \( P_n \) is the projection onto \( \mathcal{P}_n = \text{span}\{p_1, \ldots, p_n\} \) that is orthogonal with respect to the inner product induced by \( \hat{a} \).
For each \( n \), define the intermediate form
\[
a_n(u) = a_0^{(\gamma)}(u) + \tilde{a}(P_n u)
\]
for \( u \in \mathcal{D}(a_n) = \mathcal{H} \), with the corresponding selfadjoint operator
\[
A_n = A_0^{(\gamma)} + \tilde{A} P_n.
\]
By construction,
\[
a_0^{(\gamma)}(u) \leq a_n(u) \leq a_{n+1}(u) \leq a(u)
\]
for all \( u \in \mathcal{D}(a) \), and thus the second monotonicity principle provides
\[
\lambda_i(A_0) = \lambda_i(A_0^{(\gamma)}) \leq \cdots \leq \lambda_i(A_n) \leq \lambda_i(A_{n+1}) \leq \cdots \leq \lambda_i(A),
\]
for all \( i \) such that \( \lambda_i(A) < \gamma \). Thus, the intermediate operators, \( \{A_n\} \), have eigenvalues that provide improving lower bounds to the eigenvalues of \( A \) as the index \( n \) is increased. For discussion of practical issues involving computation of intermediate operator eigenvalues, see [7, 32, 33]. Convergence criteria for this approximation method are given by the following theorem [10].

**Theorem 2.1.** If the set of vectors \( \{p_i\}_{i=1}^{\infty} \) is complete in \( \mathcal{D}(A) \) with respect to the norm \( \|Au\| \), then \( \lim_{n \to \infty} \lambda_i(A_n) = \lambda_i(A) \) for each \( i \) such that \( \lambda_i(A) < \gamma \), \( \lim_{n \to \infty} \lambda_i(A_n) \geq \gamma \) for each \( i \) such that \( \lambda_i(A) \geq \gamma \), and \( \|E_\lambda[A] - E_\lambda[A_n]\| \to 0 \) as \( n \to \infty \) for every \( \lambda < \gamma \).

Our convergence rate estimates are motivated by the following conditions for exactness (cf. [11]). Define \( \mathcal{U}^{\gamma} = \mathcal{R}(E_\gamma [A]) = E_\gamma [A] \cdot \mathcal{H} \), and let \( P_n^* \) denote the adjoint of \( P_n \) in \( \mathcal{H} \), as usual.

**Theorem 2.2.** Suppose the convergence criteria of Theorem 2.1 are satisfied. If for all \( n \geq N \),
\[
(2.2) \mathcal{R}(P_n^*) \supset \mathcal{U}^{\gamma} + \mathcal{U}_0^{\gamma},
\]
then for all \( n \geq N \),
\[
(2.3) \mathcal{R}(P_n) \supset \mathcal{U}^{\gamma},
\]
and furthermore, when (2.3) holds for \( n \geq N \), then also \( \lambda_i(A_n) = \lambda_i(A) \) for all \( n \geq N \) and each \( i \) such that \( \lambda_i(A) < \gamma \).

It is thus appropriate to seek rate of convergence estimates in terms of a notion of separation between the “approximating subspaces”, \( \mathcal{R}(P_n^*) \), and the “exact subspaces” \( \mathcal{U}^{\gamma} + \mathcal{U}_0^{\gamma} \). An appropriate measure of separation is the containment gap for a subspace \( \mathcal{N} \) by a subspace \( M \).

**Definition 2.3.** Let \( M \) and \( \mathcal{N} \) be closed subspaces of \( \mathcal{H} \) with \( \dim \mathcal{N} > 0 \). The containment gap for \( \mathcal{N} \) by \( M \) is
\[
\delta_{\mathcal{N}}(M) = \sup_{0 \neq u \in \mathcal{N}} \frac{\|(I-Q)u\|}{\|u\|} = \|(I-Q)P\|,
\]
where \( Q \) is the orthogonal projection onto \( \mathcal{M} \) and \( P \) is the orthogonal projection onto \( \mathcal{N} \).

Unlike the gap of [23, p. 197], \( \delta_{\mathcal{N}}(M) \) is not symmetric in \( M \) and \( \mathcal{N} \), and \( \delta_{\mathcal{N}}(M) = 0 \) if and only if \( M \supset \mathcal{N} \). We now state the basic estimate of [11]. Herein we let \( \mathcal{R}_n = \mathcal{R}(P_n) \), and then one has \( \tilde{A} \mathcal{R}_n = \mathcal{R}(P_n^*) \).
Theorem 2.4. There exists a constant $K > 0$, independent of $n$, such that for each $i$ satisfying $\lambda_i(A) < \gamma$,

$$|\lambda_i(A) - \lambda_i(A_n)| \leq K \{ \delta_\mathcal{L}(\tilde{A}_n) + \delta_\mathcal{M}(\tilde{A}_n) \},$$

where $\mathcal{L} = \mathcal{U}_0^\gamma$ and $\mathcal{M} = \mathcal{U}_\gamma$.

Observe that the convergence criteria of Theorem 2.1 are not hypothesized in Theorem 2.4. Thus Theorem 2.4 immediately yields the following theorem, which is reminiscent of conditions for convergence of Weinberger's method [30, 32]. Herein, $\text{cl}(Z)$ represents the closure of a set $Z$ in the underlying Hilbert space $\mathcal{H}$.

Theorem 2.5. If $\text{cl}(\bigcup_{n=1}^{\infty} \tilde{A}_n) \supset \mathcal{U}_\gamma + \mathcal{U}_0^\gamma$, then $\lim_{n \to \infty} \lambda_i(A_n) = \lambda_i(A)$ for all $i$ such that $\lambda_i(A) < \gamma$.

To improve on the estimate of Theorem 2.4, we use the following eigenvalue estimate due to Kato [22]. The estimate (2.5) for eigenprojections is contained within Kato's proof of Lemma 18.4 in [22], and is also developed in [18] together with the explicit eigenvector bound (2.6). As usual, $\delta_{kl}$ denotes the Kronecker symbol.

Theorem 2.6. For $S$ a selfadjoint operator in $\mathcal{H}$, let $v_1, \ldots, v_m \in \mathcal{D}(S)$ be $m$ vectors for which

$$\langle v_k, v_l \rangle = \delta_{kl}, \quad \langle S v_k, v_l \rangle = \eta_k \delta_{kl}, \quad k, l = 1, \ldots, m,$$

$$\eta_1 \leq \eta_2 \leq \cdots \leq \eta_m,$$

and let $\theta_k = \| (S - \eta_k) v_k \|$, $k = 1, \ldots, m$. Further, let $(c, d)$ be an interval whose intersection with the spectrum of $S$ consists solely of eigenvalues of total multiplicity at most $m$. If $c < \eta_1$, $\eta_m < d$, and

$$\sum_{k=1}^{m} \frac{\theta_k^2}{(\eta_k - c)(d - \eta_k)} < 1,$$

then there are exactly $m$ eigenvalues $\Lambda_1 \leq \Lambda_2 \leq \cdots \leq \Lambda_m$ of $S$ in the interval $(c, d)$, and they satisfy

$$-\sum_{k=l}^{m} \frac{\theta_k^2}{d - \eta_k} \leq \Lambda_l - \eta_l \leq \sum_{k=l}^{m} \frac{\theta_k^2}{\eta_k - c}, \quad l = 1, \ldots, m.$$

Furthermore, if $P$ is the orthogonal projection onto the $m$-dimensional subspace spanned by the eigenvectors of $S$ corresponding to $\Lambda_1, \ldots, \Lambda_m$, and $\delta_k = \min\{\eta_k - c, d - \eta_k\}$, then

$$\| P v_k - v_k \| \leq \theta_k / \delta_k, \quad k = 1, \ldots, m.$$

If $m = 1$ and $w_1$ is the corresponding eigenvector of $S$ normalized by $\| w_1 \| = 1$ and $\langle w_1, v_1 \rangle \geq 0$, then

$$\| w_1 - v_1 \|^2 \leq 2 \theta_1^2 / \delta_1^2 [1 + (\theta_1^2 / \delta_1^2)]^{1/2}.$$

3. Convergence rates

We begin with a rate of convergence estimate for the eigenvalues of $A$ below $\gamma$. The proof is based on an implementation of Theorem 2.6 by means of a
construction of [11, 19], which is also basic to the proof of Theorem 2.4. We sketch this construction in the course of the proof, but full details are available in [11, 19].

**Theorem 3.1.** Let \( \lambda_h(A) = \lambda_{h+1}(A) = \cdots = \lambda_{h+m-1}(A) \) be an eigenvalue of \( A \) below \( \gamma \) with multiplicity \( m \) and corresponding eigenspace \( \mathcal{S} \). Further, assume that the convergence criteria of either Theorem 2.1 or Theorem 2.5 are satisfied. Then for each \( j = h, h+1, \ldots, h+m-1, \) and all \( n \) large enough,

\[
|\lambda_j(A) - \lambda_j(A_n)| \leq K\{\delta^2 \mathcal{M}(A_n) + \delta^2 \mathcal{N}(A_n)\},
\]

where \( \mathcal{M} = \mathcal{U}^\gamma, \mathcal{N} = \mathcal{S} + \mathcal{U}_0^\gamma \), and \( K \) is independent of \( n \).

**Proof.** Consider the truncation of \( A \) at \( \gamma \),

\[
A^{(\gamma)} = AE_{\gamma-}[A] + \gamma(I-E_{\gamma-}[A]),
\]

and introduce the auxiliary self-adjoint operator,

\[
A' = A^{(\gamma)} + P_n(A^{(\gamma)} - A^{(\gamma)})P_n.
\]

It follows easily that \( \langle A'u, u \rangle \leq \langle A_nu, u \rangle \) for all \( u \in \mathcal{S} \), so

\[
|\lambda_j(A) - \lambda_j(A_n)| \leq |\lambda_j(A) - \lambda_j(A')| \leq |\lambda_j(A) - \eta_k| + |\eta_k - \lambda_j(A')|,
\]

where \( \eta_k \) will be specified below. Evidently, it will suffice to prove that the last two terms are dominated by the right-hand side of (3.1).

We now assume that \( A \) is bounded, and will treat the unbounded case later. We will employ Theorem 2.6 with \( S = A' \), \((c, d)\) any isolating interval for \( \lambda_k(A) \), and \( \{v_k\}_{k=1}^m \) an orthonormal basis for the eigenspace \( \mathcal{S} \) which also diagonalizes the \( m \times m \) matrix \( [(A'nv_k, v_k)] \), yielding matrix eigenvalues \( \eta_1 \leq \eta_2 \leq \cdots \leq \eta_m \) given by \( \eta_k = (A'nv_k, v_k), \ k = 1, \ldots, m. \) Then \( \theta_k = \|A'v_k - \eta_kv_k\|, \) for \( k = 1, \ldots, m. \) The vectors \( v_k \) and the numbers \( \eta_k, \theta_k \) may depend on \( n \), but we are free to use a notation that suppresses that dependence.

Thus,

\[
\eta_k - \lambda_h(A) = \eta_k - \langle A^{(\gamma)}v_k, v_k \rangle = \langle (A' - A^{(\gamma)})v_k, v_k \rangle
\]

\[
= \langle (A' + P_n(A^{(\gamma)} - A^{(\gamma)})P_n - A')v_k, v_k \rangle
\]

\[
= \langle (P_n - I)(A^{(\gamma)} - A^{(\gamma)})(P_n - I) + (A^{(\gamma)} - A^{(\gamma)})(P_n - I)
\]

\[
\quad + (P_n - I)(A^{(\gamma)} - A^{(\gamma)})v_k, v_k \rangle.
\]

Now,

\[
\langle (P_n - I)(A^{(\gamma)} - A^{(\gamma)})v_k, v_k \rangle
\]

\[
= \langle (P_n - I)(I - Q_n)(A^{(\gamma)} - A^{(\gamma)})v_k, v_k \rangle
\]

\[
= \langle (I - Q_n)(A^{(\gamma)} - A^{(\gamma)})v_k, (P_n - I)v_k \rangle,
\]

where \( Q_n \) is the orthogonal projection onto \( \mathcal{R}(P_n) = \mathcal{A} \mathcal{P}_n \). Hence,

\[
\|((P_n - I)(A^{(\gamma)} - A^{(\gamma)})v_k, v_k)\|
\]

\[
\leq \|((I - Q_n)(A^{(\gamma)} - A^{(\gamma)})v_k \cdot (I - P_n)v_k)\|
\]

\[
\leq (\gamma - \lambda_1(A))\delta^2 \mathcal{M}(\mathcal{A} \mathcal{P}_n)\|I - P_n\|v_k\|
\]
where $\mathcal{N} = \mathcal{S} + \mathcal{P}_0^{(y)}$. The last inequality uses the facts that $\|v_k\| = 1$, $(A^{(y)} - A_0^{(y)})v_k = (\lambda_h(A) - A_0^{(y)})v_k \in \mathcal{N}$, and $\|A^{(y)} - A_0^{(y)}\| \leq \gamma - \lambda_1(A_0)$. Now observe that, since $\tilde{A}(I - P_n)$ is selfadjoint,

$$\|(I - P_n)v_k\| \leq \alpha^{-1}\|\tilde{A}(I - P_n)v_k\| = \alpha^{-1}\|(I - P_n^*)\tilde{A}v_k\|.$$ 

Since $P_n$ and $I - P_n$ are $\tilde{\alpha}$-symmetric for each $n$, and $\tilde{\alpha}$ is bounded, we have the uniform bound $\|P_n - I\| = \|P_n^* - I\| \leq \kappa$, where $\kappa = \|A_1^{1/2}\| \cdot \|A^{-1/2}\|$ with $A_1^{1/2}$ the unique positive definite square root of $A$. Hence,

$$\|(I - P_n)v_k\| \leq \alpha^{-1}\|(I - P_n^*)(I - Q_n)\tilde{A}v_k\| \leq \alpha^{-1}\kappa\|(I - Q_n)\tilde{A}v_k\| \leq \alpha^{-1}\kappa(\gamma - \lambda_1(A_0))^2\delta_\mu(\tilde{A}\mathcal{P}_n),$$

since $\|v_k\| = 1$ and $\tilde{A}v_k = (A - A_0^{(y)})v_k = (\lambda_h(A) - A_0^{(y)})v_k$. Thus,

$$\|\langle(A^{(y)} - A_0^{(y)})(P_n - I)v_k, v_k\rangle\| = \|\langle(A^{(y)} - A_0^{(y)})(P_n - I)v_k, v_k\rangle\| \leq \alpha^{-1}\kappa(\gamma - \lambda_1(A_0))^2\delta_\mu(\tilde{A}\mathcal{P}_n),$$

and similarly,

$$\|\langle(P_n^* - I)(A^{(y)} - A_0^{(y)})(P_n - I)v_k, v_k\rangle\| = \|\langle(A^{(y)} - A_0^{(y)})(P_n - I)v_k, (P_n - I)v_k\rangle\| \leq \kappa(\gamma - \lambda_1(A_0))\|(P_n - I)v_k\|^2 \leq \alpha^{-1}\kappa(\gamma - \lambda_1(A_0))^2\delta_\mu(\tilde{A}\mathcal{P}_n).$$

Thus, $|\eta_k - \lambda_h(A)| \leq K_1\delta_\mu(\tilde{A}P_n)$, for some constant $K_1$ independent of $n$. Note that

$$\theta_k = \|[(A^{(y)} + (A'_n - A^{(y)}) - (\lambda_h(A) + \langle(A'_n - A^{(y)})v_k, v_k\rangle)]v_k\| \leq \|A'_n - A^{(y)}\|.$$

Furthermore, Lemmas 3.1 and 3.2 of [11] together yield

$$\|A'_n - A^{(y)}\| \leq C\{\delta(\tilde{A}\mathcal{P}_n) + \delta(\tilde{A}\mathcal{P}_n)\},$$

where $\mathcal{L} = \mathcal{U}_0^\gamma$, $\mathcal{M} = \mathcal{U}_0^\gamma$, and the positive constant $C$ is independent of $n$, and so

$$\theta_k^2 \leq 2C^2\{\delta(\tilde{A}\mathcal{P}_n) + \delta(\tilde{A}\mathcal{P}_n)\}.$$ 

As $n \to \infty$, the convergence criteria imply that $\theta_k \to 0$ and $\eta_k \to \lambda_h(A)$ for each $k = 1, 2, \ldots, m$ and that $\lambda_j(A'_n) \to \lambda_h(A)$ for each $j = h, h + 1, \ldots, h + m - 1$. The hypotheses of Theorem 2.6 hold for sufficiently large $n$, hence for each $j = h, h + 1, \ldots, h + m - 1$ there is an index $1 \leq k(j) \leq m$ and a constant $K_2$ independent of $n$ such that

$$|\eta_{k(j)}(j) - \lambda_j(A'_n)| \leq K_2\theta_{k(j)}^2 \leq 2K_2C\{\delta(\tilde{A}\mathcal{P}_n) + \delta(\tilde{A}\mathcal{P}_n)\}.$$ 

The conclusion (3.1) now follows immediately.

We now admit the possibility that $A$ is unbounded and observe that the above proof does not apply, since in that case there may not be a bound independent of $n$ for $\|P_n - I\| = \|P_n^* - I\|$. This difficulty will be circumvented by employing a device of [19] which was also used in [11]. We assume without loss of generality...
that the quadratic form \( \langle A_0^{(\gamma)} u, u \rangle \) is nonnegative and consider the auxiliary bounded selfadjoint operator
\[
\tilde{A} = A^{(\mu)} - A_0^{(\gamma)},
\]
where \( \mu \) is some fixed positive number satisfying \( \mu \geq \gamma(1 + (2\gamma/\alpha)) + (\alpha/2) \). Then the corresponding quadratic form satisfies \( \tilde{a}(u) \geq (\alpha/2)\|u\|^2 \) for all \( u \in \mathcal{H} \) (cf. [19]). It follows that
\[
a^{(\mu)}(u) = a_0^{(\gamma)}(u) + \tilde{a}(u),
\]
and we apply Aronszajn's method to this decomposition of \( a^{(\mu)} \) in the following way.

Given the trial vectors \( \{p_i\}_{i=1}^\infty \subset \mathcal{D}(A) \), generate \( \{\tilde{p}_i\}_{i=1}^\infty \) by \( \tilde{p}_i = A - A_0 \tilde{A} p_i \) for each \( i = 1, 2, \ldots \). Define projections \( \tilde{P}_n \) onto \( \tilde{S}_n = \text{span}\{\tilde{p}_1, \ldots, \tilde{p}_n\} \) by
\[
\tilde{P}_n u = \sum_{i,j=1}^n \langle u, \tilde{A} \tilde{p}_i \rangle \tilde{b}_{ij} \tilde{p}_j, \quad u \in \mathcal{H},
\]
where \( [\tilde{b}_{ij}] \) is the matrix inverse to \( [\langle \tilde{p}_i, \tilde{A} \tilde{p}_j \rangle] \). Then \( \tilde{P}_n \) is an orthogonal projection with respect to the inner product induced by \( \tilde{a}(u) \) defined so that for each \( n \),
\[
\tilde{a}(I - \tilde{P}_n) = \tilde{a}(I - P_n) \quad \text{and} \quad \tilde{a}(\tilde{P}_n) = \tilde{a}(P_n).
\]
Moreover, \( \tilde{a}(\tilde{P}_n u) \leq \tilde{a}(P_n u) \) for all \( u \in \mathcal{H} \) (cf. [11, 19]). Hence, the intermediate operators
\[
A''_n = A_0^{(\gamma)} + \tilde{A} \tilde{P}_n
\]
yield eigenvalues \( \lambda_i(A''_n) \) which for each \( i \) with \( \lambda_i(A) < \gamma \) satisfy \( \lambda_i(A''_n) \leq \lambda_i(A) \leq \lambda_i(A_0^{(\gamma)}) \), and \( \lambda_i(A''_n) \to \lambda_i(A^{(\mu)}) = \lambda_i(A) \) as \( n \to \infty \).

Now, since \( A^{(\mu)} \) and \( \tilde{A} = A^{(\mu)} - A_0^{(\gamma)} \) are bounded, the preceding proof for the case of bounded operators yields a constant \( K \) independent of \( n \) such that
\[
|\lambda_j(A^{(\mu)}) - \lambda_j(A''_n)| \leq K \{ \delta^2_\mathcal{M}(\tilde{A} \tilde{P}_n) + \delta^2_\mathcal{N}(\tilde{A} \tilde{P}_n) \},
\]
where \( \mathcal{M} = \mathcal{U}^{\gamma} \) and \( \mathcal{N} = \mathcal{S} + \mathcal{U}_0^{\gamma} \). The proof is now complete, since
\[
\lambda_j(A^{(\mu)}) = \lambda_j(A) \geq \lambda_j(A''_n) \geq \lambda_j(A''_n) \quad \text{and},
\]
by construction, \( \tilde{a}(\tilde{P}_n) = \tilde{a}(P_n) \).

Since the proof of Theorem 3.1 actually proceeds by estimating the differences between the unknown eigenvalues and eigenvectors of the auxiliary operator \( A''_n \) and those of \( A \), it fails to provide useful estimates for the eigenvectors or eigenprojections of \( A_n \). Our next theorem provides such estimates, but yields eigenvalue estimates which are in practice not as good as those of Theorem 3.1.

**Theorem 3.2.** Let \( \lambda_h(A) = \lambda_{h+1}(A) = \cdots = \lambda_{h+m-1}(A) \) be an eigenvalue of \( A \) below \( \gamma \) with multiplicity \( m \) and corresponding eigenspace \( \mathcal{S} \). Let \( P \) be the orthogonal projection onto \( \mathcal{S} \), and let \( \tilde{P} \) be the projection onto \( \mathcal{S} \) which is orthogonal with respect to the inner product induced by \( \tilde{a} \). Further assume that the convergence criteria of Theorem 2.1 or of Theorem 2.5 are satisfied and that
\[ \|P^*_n\| \delta \gamma(\tilde{A} \mathcal{P}_n) \rightarrow 0 \text{ as } n \rightarrow \infty, \text{ where } \mathcal{N} = \mathcal{S} + \mathbb{R}_0^+ \text{. Then for each } j = h, h+1, \ldots, h+m-1, \text{ and all } n \text{ large enough,} \]

(3.2) \[ |\lambda_j(A) - \lambda_j(A_n)| \leq K\{\|\tilde{A}^{1/2}(I - P_n)\tilde{P}\|^2 + \|P^*_n\|^2 \delta^2 \gamma(\tilde{A} \mathcal{P}_n)\} \]

and

(3.3) \[ \|R_n P - P\| \leq K\|P^*_n\| \delta \gamma(\tilde{A} \mathcal{P}_n), \]

where \( R_n \) is the orthogonal projection onto the \( m \)-dimensional space spanned by the eigenvectors of \( A_n \) corresponding to the eigenvalues \( \{\lambda_j(A_n)\}_{j=h}^{h+m-1} \). In particular, if \( m = 1, \) \( n \) is large enough, and the eigenvector \( u^n_h \) of \( A_n \) corresponding to \( \lambda_h(A_n) \) is normalized by \( \|u^n_h\| = 1 \) and \( \langle u^n_h, u_h \rangle \geq 0 \),

(3.4) \[ \|u^n_h - u_h\| \leq K\|P^*_n\| \delta \gamma(\tilde{A} \mathcal{P}_n). \]

Herein, \( K \) is a generic constant independent of \( n \).

**Proof.** We use Theorem 2.6 with \( S = A_n, \) \((c, d)\) any isolating interval for \( \lambda_h(A) \), and \( \{v_k\}_{k=1}^m \) an orthonormal basis for the eigenspace \( \mathcal{S} \) which also diagonalizes the \( m \times m \) matrix \( [(A_n v_k, v_k)] \), yielding eigenvalues \( \eta_1 \leq \eta_2 \leq \cdots \leq \eta_m \) given by \( \eta_k = \langle A_n v_k, v_k \rangle, \) \( k = 1, \cdots, m \). Then

\[ \eta_k = \langle A v_k, v_k \rangle + \langle (A_n - A) v_k, v_k \rangle = \lambda_h(A) + \langle \tilde{A}(P_n - I) v_k, v_k \rangle = \lambda_h(A) + \tilde{a}((P_n - I) v_k) \]

so that

\[ |\eta_k - \lambda_h(A)| \leq \|\tilde{A}^{1/2}(P_n - I)\tilde{P}\|^2, \]

and

\[ \theta_k = \|(A_n - \eta_k) v_k\| = \|\tilde{A}(P_n - I) - \tilde{A}(P_n - I) v_k, v_k\| v_k\| \]

\[ \leq \|\tilde{A}(P_n - I) v_k\|. \]

Thus, since \( \tilde{A}(P_n - I) \) is selfadjoint,

\[ \theta_k \leq \|(P^*_n - I)\tilde{A} v_k\| = \|(P^*_n - I)(I - Q_n)\tilde{A} v_k\| \leq \|(P^*_n\| + 1)\|(I - Q_n)\tilde{A} v_k\|, \]

where \( Q_n \) is the orthogonal projection onto \( \mathcal{R}(P^*_n) = \tilde{A} \mathcal{P}_n \). Now, \( \|P^*_n\| \geq 1 \), \( \tilde{A} v_k = (\lambda_h(A) - A_0) v_k \in \mathcal{N} \), and \( \|\tilde{A} v_k\| \leq \gamma - \lambda_1(A_0) \), so

\[ \theta_k \leq 2\|P^*_n\|(\gamma - \lambda_1(A_0)) \delta \gamma(\tilde{A} \mathcal{P}_n). \]

By hypothesis, \( \theta_k \rightarrow 0 \) and \( \eta_k \rightarrow \lambda_h(A) \) as \( n \rightarrow \infty \), so Theorem 2.6 implies the conclusions of the theorem. \( \square \)

**4. Applications**

In order to apply the preceding estimates to differential eigenvalue problems, it is convenient to dominate the containment gaps of Theorems 3.1 and 3.2 in terms of spectral projections of an auxiliary operator \( B \). Specifically, let \( B \) be a positive definite selfadjoint operator in \( \mathcal{S} \) such that \( \mathcal{D}(B) \subset \mathcal{D}(\tilde{A}) \) and \( \|Au\| \leq \beta\|Bu\|, \) \( \beta > 0 \), for all \( u \in \mathcal{D}(B) \), with \( B^{-1} \) compact. Let

\[ 0 < \mu_1 \leq \mu_2 \leq \cdots \leq \mu_i \leq \cdots \leq \infty \]
be the eigenvalues of $B$ enumerated as usual according to multiplicity, with corresponding eigenvectors $\{p_i\}$ orthonormal in $\mathcal{H}$. If these vectors $\{p_i\}$ are employed as the trial vectors to construct the projection operators $\{P_n\}$ of (2.1), then the following estimate is obtained in [11].

**Theorem 4.1.** If for all eigenvalues $\lambda_i(A)$ and $\lambda_i(A_0)$ less than $\gamma$, both $u_i$ and $(A - \gamma)^{-1}u_i^\tau$ are in $\mathcal{D}(B^\tau)$ with $\tau > 1$, then

\[
\delta_\mathcal{F}(\widetilde{AP}_n) = o(\mu_n^{1-\tau}) \quad \text{as } n \to \infty,
\]

where $\mathcal{F} = \mathcal{U}^\tau + \mathcal{U}_0^\tau$.

Herein, $o$ is the usual Landau symbol, $B^\tau$ denotes the unique positive definite $\tau$th power of $B$, and we assume without loss of generality that $\gamma$ is in the resolvent set of $A$. Since both $\mathcal{U}^\tau$ and $\mathcal{F} + \mathcal{U}_0^\tau$ are contained in $\mathcal{U}^\tau + \mathcal{U}_0^\tau$, this provides a technique for implementing Theorem 3.1.

A closely related, but simpler, analysis than that leading to (4.1) yields

\[
\|A^{1/2}(I - P_n)\tilde{P}\|^2 = o(\mu_{n+1}) \quad \text{as } n \to \infty,
\]

under slightly weaker hypotheses than those of Theorem 4.1. This reveals that as long as (4.1) is used to estimate $\delta_\mathcal{F}(\widetilde{AP}_n)$, $\mathcal{N} = \mathcal{F} + \mathcal{U}_0^\tau$, the eigenvalue estimate of Theorem 3.2 can only be as good asymptotically as that of Theorem 3.1 if $\{\|P_n\|\}$ is bounded, unless $\|P_n\|\delta_\mathcal{F}(\widetilde{AP}_n) = O(\delta_\mathcal{F}(\widetilde{AP}_n))$ as $n \to \infty$. We now estimate $\|P_n\|$ in terms of $\mu_n$, so that Theorem 3.2 may be applied to obtain eigenvector and eigenprojection estimates in differential problems.

**Theorem 4.2.** One has $\|P_n\| = \|P_n\| = (\beta/\rho)\mu_n$. Further, let $b(u)$ be the closure of the quadratic form $\langle Bu, u \rangle$. If also $\mathcal{D}(\tilde{a}) \subset \mathcal{D}(b)$, and there exists $\rho > 0$ such that $\rho b(u) \leq \tilde{a}(u)$ for all $u \in \mathcal{D}(\tilde{a})$, then

\[
\|P_n\| \leq (\beta/\rho) \left( \mu_n \sum_{i=1}^n \mu_i^{-1} \right)^{1/2}.
\]

**Proof.** Recall that $Bp_i = \nu_i p_i$, and take $(p_i, p_j) = \delta_{ij}$. Further select vectors $q_1, \ldots, q_n$ satisfying $\text{span}\{q_1, \ldots, q_n\} = \text{span}\{p_1, \ldots, p_n\} = \mathcal{P}_n$, $(q_i, q_j) = \delta_{ij}$, $\tilde{a}(q_i, q_j) = \eta_i \delta_{ij}$ with $\eta_1 \leq \eta_2 \leq \cdots \leq \eta_n$. Then

\[
P_n u = \sum_{i=1}^n \frac{\langle u, \tilde{A}q_i \rangle}{\eta_i} q_i,
\]

so that

\[
P_n^* u = \sum_{i=1}^n \frac{\langle u, q_i \rangle}{\eta_i} \tilde{A}q_i.
\]

Define $\sigma_1, \ldots, \sigma_n$ by

\[
\sum_{i=1}^n \frac{\langle u, q_i \rangle}{\eta_i} q_i = \sum_{i=1}^n \sigma_i p_i.
\]

Then,

\[
P_n^* u = \tilde{A}B^{-1} \left( \sum_{i=1}^n \sigma_i \mu_i p_i \right).
\]
and so,
\[ \| P^* u \|^2 \leq \| \tilde{A}^{-1} \| ^2 \sum_{i=1}^{n} \sigma_i^2 \mu_i^2 \leq \beta^2 \mu_n^2 \sum_{i=1}^{n} \sigma_i^2 \]
\[ = \beta^2 \mu_n^2 \sum_{i=1}^{n} \frac{|\langle u, q_i \rangle|^2}{\eta_i^2} \leq (\beta / \alpha)^2 \mu_n^2 \| u \|^2, \]
i.e., \( \| P^* u \| \leq (\beta / \alpha) \mu_n \).

To obtain (4.2), first note that, if also \( pb(u) \leq \tilde{a}(u) \), then
\[ \sum_{i=1}^{n} \sigma_i^2 \mu_i = b \left( \sum_{i=1}^{n} \sigma_i \rho_i \right) \leq \rho^{-1} \tilde{\alpha} \left( \sum_{i=1}^{n} \frac{\langle u, q_i \rangle}{\eta_i} \right) = \rho^{-1} \sum_{i=1}^{n} \frac{|\langle u, q_i \rangle|^2}{\eta_i}. \]

Now \( \{ \eta_i \} \) are the Rayleigh-Ritz eigenvalues of \( \tilde{A} \) corresponding to the subspace \( \mathcal{P}_n \). Since \( pb(u) \leq \tilde{a}(u) \), these dominate the Rayleigh-Ritz eigenvalues of \( \rho B \) corresponding to the subspace \( \mathcal{P}_n \). Thus, \( \rho \mu_i \leq \eta_i, \ i = 1, \ldots, n \). So,
\[ \sum_{i=1}^{n} \sigma_i^2 \mu_i \leq \rho^{-2} \left( \sum_{i=1}^{n} \mu_i^{-1} \right) \| u \|^2. \]

Hence,
\[ \| P^* u \|^2 \leq \| \tilde{A}^{-1} \| ^2 \sum_{i=1}^{n} \sigma_i^2 \mu_i^2 \leq \beta^2 \mu_n^2 \sum_{i=1}^{n} \sigma_i^2 \mu_i \]
\[ \leq (\beta / \rho)^2 \mu_n \left( \sum_{i=1}^{n} \mu_i^{-1} \right) \| u \|^2, \]
which completes the proof. \( \square \)

5. Examples

Two examples of convergence rates for differential eigenvalue problems, with one involving nontrivial essential spectrum, were given previously in [11]. For those examples, Theorem 3.1 squares the convergence rate estimates of [11] for eigenvalues, and Theorem 3.2 provides rate of convergence estimates for eigenvectors and eigenprojections. We present here additional applications to Sturm-Liouville problems, which allow direct comparison of our results with those of [12, 15] for the method of special choice.

Let \( \mathfrak{H} = L^2(0, 1) \) and, for \( u \in H^1_0(0, 1) \)—the closure of \( C^0_0(0, 1) \) in the Sobolev space \( H^1(0, 1) \)—let
\[ a(u) = \int_0^1 (|u'|^2 + q|u|^2) \, dx, \]
where \( q \) is a nonnegative function in \( C^3(0, 1) \). Then \( \mathfrak{D}(A) = H^2(0, 1) \cap H^1_0(0, 1) \), and the eigenvalue problem for \( A \) means
\[ Au = -u'' + qu = \lambda u \quad \text{in} \ (0, 1), \quad u(0) = u(1) = 0. \]

Let
\[ a_0(u) = \int_0^1 |u'|^2 \, dx, \quad u \in H^1_0(0, 1), \]
i.e.,

\[ A_0 u = -u'' \quad \text{in} \ (0, 1), \quad u(0) = u(1) = 0. \]

If we take \( B = A_0 \), so that \( p_k = u_k^0 \) and \( \mu_k = \lambda_k^0 = k^2 \pi^2 \), both (4.1) and (4.2) apply. To find \( \tau \) in (4.1), first note that with \( \lambda_j \equiv \lambda_j(A) \),

\[ Bu_j = A_0 u_j = \lambda_j u_j - qu_j \in H^2(0, 1) \cap H_0^1(0, 1), \]

and so

\[ A_0 u_j = (\lambda_j^2 - 2 \lambda_j q + q^2 + q''(x))u_j + 2q'u_j \in H^1(0, 1). \]

so that \( u_j \in \mathcal{D}(B^\tau) = \mathcal{D}(A_0^\tau) \) for all \( \tau < 9/4 \) (cf. either of [17, 20]). In addition,

\[ A_0(A - \gamma)^{-1}u_j^0 = u_j^0 + (\gamma - q)(A - \gamma)^{-1}u_j^0 \in H^2(0, 1) \cap H_0^1(0, 1), \]

and

\[ A_0^2(A - \gamma)^{-1}u_j^0 = (\lambda_j + \gamma - q)u_j^0 + q''(A - \gamma)^{-1}u_j^0 \\
+ 2q'(A - \gamma)^{-1}u_j^0' + (\gamma - q)^2(A - \gamma)^{-1}u_j^0 \in H^1(0, 1), \]

so that \( (A - \gamma)^{-1}u_j^0 \in \mathcal{D}(A_0^\tau) \) for all \( \tau < 9/4 \). Thus, since \( \mu_n = \lambda_n^0 = n^2 \pi^2 \), Theorems 3.1 and 4.1 yield

\[ |\lambda_j(A) - \lambda_j(A_n)| = o(n^{-\delta}) \quad \text{as} \quad n \to \infty \quad \text{for all} \quad \delta < 5. \]

If we were to integrate by parts on the expressions for \( A_0^2u_j \) and \( A_0^2(A - \gamma)^{-1}u_j^0 \) as in [12], we could improve this estimate to \( O(n^{-5}) \) as \( n \to \infty \), which is the convergence rate given in [12, 15] for the method of special choice. Since the eigenvalues of \( A \) are simple, Theorem 3.2, Theorem 4.1, and (conclusion (4.2) of) Theorem 4.2 now give the eigenvector estimate

\[ \|u_{i}^{[n]} - u_{i}\| = o(n^{-\delta}) \quad \text{as} \quad n \to \infty \quad \text{for all} \quad \delta < 3/2, \]

which would improve to \( O(n^{-3/2}) \) by use of integration by parts in the fashion mentioned above. The special choice rate of [12, 15] is \( O(n^{-5/2}) \).

In order to illustrate the derived eigenvalue rate in this setting, we consider the parabolic cylinder equation, which is obtained by setting \( q(x) = x^2 \) above. Intermediate problems are constructed as described in §2, using base problem eigenfunctions to define the projection subspaces \( \mathcal{P}_n = \text{span}\{u_1^0, u_2^0, \ldots, u_n^0\} \). The value of \( \gamma \) is fixed at 90.0, leaving three base problem eigenvalues below the truncation point. Resolution of the resulting intermediate problem of order \( n \) requires the solution of a generalized matrix eigenvalue problem of dimension \( 3 + n \) given by

\[ (5.1) \quad \begin{bmatrix} F & G' \\ G & H \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix} = (\lambda - \gamma) \begin{bmatrix} R & 0 \\ 0 & S \end{bmatrix} \begin{bmatrix} x_1 \\ x_2 \end{bmatrix}, \]

where \( R = \text{diag}\{\|u_1^0\|^2/(\lambda_1^0 - \gamma)\}, \ S = \{(p_k, \tilde{A}p_k)\}, \ F = \text{diag}\{\|u_i^0\|^2\}, \ G = \{(u_i^0, \tilde{A}p_i)\}, \) and \( H = \{(A p_k, A p_i)\} \). Calculations were performed on a Sun 3/60 workstation in double precision (unit roundoff \( \approx 1.1 \times 10^{-16} \)). The QZ method [24] was used to solve the matrix eigenvalue problem (5.1). Matrix eigenvalues associated with bounds were computed to an estimated relative accuracy exceeding \( 10^{-12} \). A selection of results is listed in Table 1 and summarized graphically in Figure 1. Complementary upper bounds were found with a

Rayleigh-Ritz calculation of order 40, using base problem eigenfunctions as trial functions. In order to gauge rates of convergence, Figure 1 presents eigenvalue bracket widths plotted against intermediate problem order $n$, on a log-log scale. Parallel linear asymptotes are evident in each case, with calculated slopes lying between 4.95 and 4.98. This is within a 1% deviation from the theoretically predicted asymptotic slope of 5.

If, for the general Sturm-Liouville problem above, the potential $q(x) \in C^3(0, 1)$ also satisfies the additional condition $q'(0) = q'(1) = 0$, then $A_\eta u_j$ and $A_\alpha^2 (A-\gamma)^{-1} u_j^0$ are in $H^1_0(0, 1)$, so that $u_j$ and $(A-\gamma)^{-1} u_j^0$ are in $\mathcal{D}(A_{0}^{3/2})$.

Hence, 

$$|\lambda_i(A) - \lambda_i(A_n)| = o(n^{-6}) \quad \text{as} \quad n \to \infty,$$

and

$$||u_i^{[n]} - u_i|| = o(n^{-2}) \quad \text{as} \quad n \to \infty.$$
More rapid rates of convergence follow from additional smoothness of \( q \) and the vanishing of additional derivatives of \( q \) at 0 and 1.

Still more rapid rates occur if we were to consider periodic boundary conditions in the preceding. That is, let \( \mathcal{H} = L^2(0, 1) \), let \( q \) be the restriction to \((0, 1)\) of a nonnegative periodic \( C^\infty \) function with period 1, and for \( u \in \{ v \in H^1(0, 1) : v(0) = v(1) \} \) let

\[
a(u) = \int_0^1 (|u'|^2 + q|u|^2) \, dx.
\]

This means

\[
Au = -u'' + qu \quad \text{in } (0, 1), \ u(0) = u(1), \ u'(0) = u'(1).
\]

Take

\[
a_0(u) = \int_0^1 |u'|^2 \, dx, \quad u \in \mathcal{D}(a_0) = \mathcal{D}(a),
\]

which means

\[
A_0u = -u'' \quad \text{in } (0, 1), \ u(0) = u(1), \ u'(0) = u'(1).
\]

The methods of the preceding example may be followed to obtain an “infinite order of convergence” for the eigenvalues and eigenprojections, i.e., \( o(n^{-\delta}) \) for every \( \delta > 0 \). These conclusions are the same as for the method of special choice \([12, 15]\). This rapid estimate for the eigenvalues also follows from the estimate of \([11]\).

As a final example, for \( u \in H^1(\mathbb{R}) \) let

\[
a(u) = \int_{-\infty}^{\infty} (|u'|^2 + q|u|^2) \, dx,
\]

where \( q \in C^\infty(\mathbb{R}) \cap L^2(\mathbb{R}) \) is even with \( q(0) < 0 \), \( q \) is strictly increasing on \([0, x_1]\) to a positive maximum at \( x_1 \), and \( q \) is decreasing on \([x_1, \infty)\) with \( q \) and all derivatives of \( q \) tending to zero at infinity. Some of the conditions on \( q \) can be relaxed in the following, but these hypotheses are consistent with typical potential well considerations in quantum mechanics and provide for ease of exposition. Then, with \( \mathcal{H} = L^2(\mathbb{R}) \), \( \mathcal{D}(A) = H^2(\mathbb{R}) \), the eigenvalue problem for \( A \) means

\[
(5.2) \quad -u'' + qu = \lambda u \quad \text{on } \mathbb{R}, \ u \in L^2(\mathbb{R}).
\]

Let \( x_0 \) be the unique zero of \( q \) in \((0, x_1)\). An explicitly solvable lower bound problem is obtained from

\[
(5.3) \quad -u'' + q_0 u = \lambda u \quad \text{on } \mathbb{R}, \ u \in L^2(\mathbb{R}),
\]

with \( q_0 \) the “square well” potential:

\[
q_0(x) = \begin{cases} 
q(0) + \gamma, & -x_0 \leq x \leq x_0, \\
\gamma, & |x| > x_0.
\end{cases}
\]

Herein, \( \gamma < 0 \) is great enough that all negative eigenvalues of \( A \) are less than \( \gamma \). The negative number \( \gamma \) will, as previously, be our truncation point—and has been added to the usual square well potential so that \( \tilde{a}(u) \), and therefore \( \tilde{a}(u) \),
are positive definite. This eigenvalue problem is obtained from the quadratic form,
\[ a_0(u) = \int_{-\infty}^{\infty} (|u'|^2 + q_0|u|^2) \, dx, \quad u \in H^1(\mathbb{R}), \]
and \( \mathcal{D}(A_0) = \mathcal{D}(A) = H^2(\mathbb{R}). \)

To implement Theorem 4.1, let \( B \) be the harmonic oscillator, i.e.,
\[ B = \frac{d^2}{dx^2} + x^2, \]
with \( \mathcal{D}(B) = H^2(\mathbb{R}) \cap \mathcal{D}(x^2) \), where, as usual,
\[ \mathcal{D}(x^2) = \left\{ u \in L^2(\mathbb{R}) : \int_{-\infty}^{\infty} x^4 |u(x)|^2 \, dx < \infty \right\}. \]

Then \( B \) is selfadjoint on \( \mathcal{D}(B) \) (cf. [28]), and \( \mu_k = 2k - 1 \). An analysis like that of the preceding examples and pp. 225–226 of [11] yields \( u_j \in \mathcal{D}(B^\tau) \) for all \( \tau > 0 \), but only \( (A - \gamma)^{-1}u_j^0 \in \mathcal{D}(B^\tau) \) for all \( \tau < 9/4 \), owing to the jumps in \( q_0 \) at \( \pm x_0 \). On the other hand, if \( q_0 \) was in \( C^\infty(\mathbb{R}) \), we would have \( (A - \gamma)^{-1}u_j^0 \in \mathcal{D}(B^\tau) \) for all \( \tau > 0 \), and thus an infinite-order convergence, but the spectral problem for the base operator would not be explicitly solvable. We wish now to show that Lemma 3.5 of [10] can be used to convert this observation into a proof of an infinite order of convergence of the eigenvalues, starting from the square well base problem.

So let \( V_0 \in C^\infty(\mathbb{R}) \) be such that \( V_0 - \gamma \in C^\infty_0(\mathbb{R}) \) and \( V_0 \leq q_0 \). Further, let \( A_0 \) denote the one-dimensional Schrödinger operator corresponding to \( V_0 \). By regularization, such \( V_0 \) may be constructed to approximate \( q_0 \) within any desired tolerance in \( L^2(\mathbb{R}) \) (cf. [21]). Then, since
\[
\int_{-\infty}^{\infty} |(q_0 - V_0)u|^2 \, dx \leq \|u\|_{L^\infty(\mathbb{R})}^2 \cdot \|q_0 - V_0\|_{L^2(\mathbb{R})}^2 \leq \|u\|_{L^2(\mathbb{R})}^2 \cdot \|q_0 - V_0\|_{L^2(\mathbb{R})}^2
\]
for all \( u \in H^1(\mathbb{R}) \), it follows that \( A_0 \) can be chosen to approximate \( A_0 \) arbitrarily closely in the norm resolvent sense (cf. [27]). Thus, we may assume that \( A_0 \) and \( A_0 \) have the same number of eigenvalues below \( \gamma \), and then, given \( \varepsilon > 0 \), there exists such a \( V_0 \) satisfying
\[
\|A_0(\gamma)u - A_0(\gamma)u\| \leq \left[ \sum |\lambda_i(A_0) - \gamma| \langle u, u_i(A_0) \rangle u_i(A_0) \right]
\leq \varepsilon \|u\| \quad \text{for all} \quad u \in L^2(\mathbb{R}),
\]
where the summation is over all eigenvalues below \( \gamma \). Then, for each \( u \in \mathcal{H} = L^2(\mathbb{R}), \)
\[
\langle A_0(\gamma)u, u \rangle - \varepsilon \|u\|^2 \leq \langle A_0(\gamma)u, u \rangle,
\]
i.e.,
\[
\langle (A_0 - \varepsilon)^{(\gamma-\varepsilon)}u, u \rangle \leq \langle A_0(\gamma)u, u \rangle.
\]
As noted above, the intermediate problem eigenvalues obtained from the truncated base operator \( (A_0 - \varepsilon)^{(\gamma-\varepsilon)} \) have an infinite order of convergence. But
by Lemma 3.5 of [10], these give lower bounds for the intermediate problem
eigenvalues obtained from the truncated base operator $A_n^{(\gamma)}$. Hence,

$$|\lambda_i(A) - \lambda_i(A_n)| = o(n^{-\delta}) \quad \text{as} \quad n \to \infty \quad \text{for all} \quad \delta > 0.$$ 

In order to illustrate this last result, consider the one-dimensional Schrödinger
operator (5.2) with potential defined by

$$q(x) = b(x^2 - a^2) \exp(-cx^2).$$

We take (5.3) as base operator, with $x_0 = a$. For convenience, we restrict
ourselves to the even symmetry class of functions solving (5.2) and (5.3). The
lower spectrum of $A_0$ is resolvable and consists of simple eigenvalues that are
solutions in $\lambda$ to

$$\cot(a\sqrt{\lambda + \gamma + ba^2}) = \sqrt{-\left(1 + \frac{ba^2}{\lambda + \gamma}\right)}$$

lying in the interval $(\gamma - ba^2, \gamma)$. The lowest point of the essential spectrum of
$A_0$ is given by $\gamma$, and the number of eigenvalues of $A_0$ smaller than $\gamma$ (repre-
SENTED herein as $M$) is equal to the greatest integer smaller than $(a^2\sqrt{b}/\pi) + 1$.
These eigenvalues below $\gamma$ are labeled as before, $\lambda_0^0 < \lambda_1^0 < \cdots < \lambda_M^0$. The
corresponding (unnormalized) eigenfunctions of $A_0$ are given by

$$u_i^0 = \begin{cases} 
\exp\left(-a\sqrt{\gamma - \lambda_i^0}\right) \cos\left(\sqrt{\lambda_i^0 + ba^2 - \gamma} \cdot x\right), & -a \leq x \leq a, \\
\cos\left(a\sqrt{\lambda_i^0 + ba^2 - \gamma}\right) \exp\left(-\sqrt{\gamma - \lambda_i^0} \cdot |x|\right), & \text{otherwise}. 
\end{cases}$$

Intermediate problems are then constructed as described in §2, using even-
ordered Hermite functions to define the projection subspaces $\mathcal{P}_n = \text{span}(p_1, p_2, \ldots, p_n)$ (i.e., $Bp_k = (4k - 3)p_k$ for $k = 1, 2, \ldots, n$). Similar
to what was done before, resolution of the resulting intermediate problem
of order $n$ requires the resolution of a generalized matrix eigenvalue problem
dimension $M + n$, given by (5.1). In turn, these inner product matrices
may be expressed in terms of the four basic inner product matrices: $[(u_0^0, p_j)]$, $[(u_0^0, Ap_j)]$, $[(Ap_i, Ap_j)]$, and $[(Ap_i, p_j)]$. Analytical expressions may be ob-
tained for $[(Ap_i, p_j)]$ and $[(Ap_i, Ap_j)]$. However, inner products involving the
base problem eigenvectors $\{u_0^0\}$ must be evaluated through quadrature. For rea-
sons of economy and precision, the matrix elements $[(u_0^0, p_j)]$ and $[(u_0^0, Ap_j)]$
are determined from recurrence relations that are derivable from the basic three-
term recurrence for Hermite polynomials. With this approach, transcendental
function evaluations are reduced to the evaluation of the complementary error
function, erfc $z$, and the quadrature of

$$\int_0^a \cos\left(\sqrt{\lambda_i^0 + ba^2 - \gamma} \cdot x\right) \exp(-x^2/2)dx,$$

for $i = 1, 2, \ldots, M$.

---

1 Accurate calculation of the inner product matrices is a fairly involved undertaking in this
case. The authors are grateful to Mr. Gyou-Bong Lee for painstaking technical assistance in the
computations described here.

Rayleigh-Ritz (n = 20)

Results are reported here for $a = 3$, $b = 2$, and $c = 0.01$. Calculations were performed on a VAX 8800 in double precision carrying a unit roundoff $\approx 1.4 \times 10^{-17}$. Numerical quadratures were carried out in extended precision (mantissa length of 112 bits) using a globally adaptive 21 point/10 point Gauss-Kronrod scheme to an estimated relative accuracy of $10^{-14}$. As before, the matrix eigenvalue problem (5.1) was solved using the $QZ$ method [24] with eigenvalues participating in bounds found to a relative accuracy of better than $10^{-11}$. An order-20 Rayleigh-Ritz calculation using even-ordered Hermite trial functions was performed to provide complementary upper bounds. Table 2 provides a sampling of these results for three intermediate problem orders. In Figure 2, the resulting eigenvalue bracket widths are plotted against intermediate

Figure 2. Radial Schrödinger equation
problem order \( n \), on a log-log scale. Notice that no linear asymptote is apparent for any of the three error curves—consistent with the predicted infinite order of convergence.
