CONVERGENCE OF A CONTINUOUS GALERKIN METHOD
WITH MESH MODIFICATION
FOR NONLINEAR WAVE EQUATIONS

OHANNES KARAKASHIAN AND CHARALAMBOS MAKRIDAKIS

Abstract. We consider space-time continuous Galerkin methods with mesh
modification in time for semilinear second order hyperbolic equations. We
show a priori estimates in the energy norm without mesh conditions. Under
reasonable assumptions on the choice of the spatial mesh in each time step
we show optimal order convergence rates. Estimates of the jump in the Riesz
projection in two successive time steps are also derived.

1. Introduction

We consider space-time continuous Galerkin methods with mesh modification in
time for the model problem
\begin{align}
  u_{tt} - \Delta u &= f(u), \quad \text{in } \Omega \times [0, T], \\
  u &= 0, \quad \text{on } \partial \Omega \times [0, T], \\
  u(\cdot, 0) &= u_0, \quad \text{in } \Omega, \\
  u_t(\cdot, 0) &= u_1, \quad \text{in } \Omega,
\end{align}

where \( \Omega \) is a bounded domain in \( \mathbb{R}^2 \), \( u \) is a real-valued function defined on \( \overline{\Omega} \times [0, T] \),
and \( f \) is a given Lipschitz function.

The continuous Galerkin method [AM], [BL], [FP] is a space-time finite element
method whose Runge-Kutta counterpart is the class of Gauss-Legendre methods
and thus is particularly useful for hyperbolic problems where the conservation of
certain quantities is important. This method has been analyzed for linear wave
equations in [BL], [FP]. For nonlinear problems with possible singular behavior
it is important to consider methods that allow adaptive mesh refinement. In this
direction a continuous Galerkin method with mesh modification in time was pro-
posed and analyzed in [KM2] for the nonlinear Schrödinger equation; see also [D].
In [Y] a first order in time fully discrete method with mesh modification for lin-
ear hyperbolic problems is considered and error estimates in the energy norm are
derived. In this paper we continue our investigation by considering continuous
Galerkin methods with mesh modification for nonlinear wave equations of the form
(1.1). The method proposed reduces to the classical one in the linear case, [BL],
[FP], if we have the same spatial mesh for all times. For other space-time finite
element methods for the wave equation cf. [E], [HH], [J].

Mesh modification can have negative effects on the a priori analysis. In fact, in extreme cases it might cause the divergence of the numerical method, as was pointed out by Dupont [D]. Therefore the order of the method should not be taken for granted even when “reasonable” mesh modification takes place. In the error analysis we have to either impose restrictions in the selection of the mesh as was done, e.g., in [EJ] or allow new terms, known as “jump terms”, to make an appearance in the error estimates as in [KMI], [KM2]. These terms, albeit small, are multiplied by the number of time levels where a spatial mesh modification has occurred. In this paper, we have devoted special attention to this important issue. In one approach, we show how to eliminate such terms (cf. Section 4) while the second consists in obtaining superconvergence results for these terms (cf. Section 5).

The continuous Galerkin method. To introduce the method, we need some notation. Let $H^\ell = H^\ell(\Omega)$ be the standard $L^2$-based Sobolev spaces of order $\ell$ with norm $\| \cdot \|_{H^\ell}$. Also $(\cdot, \cdot)$ denotes the inner product, and $\| \cdot \|$, the corresponding norm on $L^2(\Omega)$, $\| \cdot \|_\infty$, denotes the norm of $L^\infty(\Omega)$ and $\| \cdot \|_{1, \infty}$ the norm of $W^{1, \infty}(\Omega)$. We shall also use the “energy” norm on $H^1_0(\Omega)$ by $\|(u, v)^T\| = \{\|\nabla u\|^2 + \|\nabla v\|^2\}^{1/2}$. For a space-time domain $\Omega \times I$, $L^2(I; H^2(\Omega))$ will denote the usual space of functions defined on $I$ and with values in $H^2(\Omega)$ with norm denoted by $\| \cdot \|_{L^2(I; H^2)}$.

We consider a partition of $[0, T]$, $0 = t^0 < t^1 < \cdots < t^N = T$, and we let $I_n = (t^n, t^{n+1}]$, $k_n = t^{n+1} - t^n$. We associate a partition $T_{hn}$ of $\Omega$ and a finite element space $S^0_h$ to each interval $I_n$:

$$S^0_h = \{ \chi \in H^1_0(\Omega) : \chi|_K \in \mathbb{P}_{r-1}(K), K \in T_{hn} \},$$

where $\mathbb{P}_p(S)$ is the space of polynomials of degree $p$. (We associate $S^{-1}_h$ to \{0\} but for simplicity we take $S^{-1}_h = S^0_h$.) In the sequel we shall denote by $K$ an element of the partition $T_{hn}$. Also $h_K$ stands for the diameter of the element $K$, and $h_n = \max_{K \in T_{hn}} h_K$.

For a positive integer $q$, let $V_q = V_{hk}(q)$ be the space of piecewise polynomial functions $\varphi : \Omega \times (0, T] \to \mathbb{R}$ of the form: $\varphi|_{\Omega \times I_n} = \sum_{j=0}^q t^j \chi_j(x)$, $\chi_j \in S^0_h$. Hence, the functions of $V_q$ are for each $t \in I_n$ elements of $S^0_h$, but they may be discontinuous (in $t$) at the nodes $t^n$, $n = 0, \ldots, J - 1$. For this reason, we introduce the notation $\nu^{n+} = \lim_{t \to t^n} v(t)$. Let also $V^n_q = \{ \varphi|_{\Omega \times I_n} : \varphi \in V_q \}$. Let $A^n_h : H^1_0(\Omega) \to S^0_h$ be the discrete operator defined by

$$A^n_h \varphi, \chi = (A^n_h v, \chi) = (\nabla v, \nabla \chi), \quad \forall \chi \in S^0_h,$$

and let $L^n_h : H^1_0(\Omega) \times L^2(\Omega) \to S^0_h \times S^0_h$ be defined by

$$L^n_h = \begin{pmatrix} 0 & -I \\ A^n_h & 0 \end{pmatrix}.$$

Henceforth, $(\cdot, \cdot)$ will denote the usual $L^2$ inner product on the product space $L^2 \times L^2$.

We will consider approximations of (1.1) written in the usual first order (in time) system form. In particular we will seek $U \in V_q \times V_q$, $U = (U_1, U_2)^T \approx (u, u_t)^T$ such
that
\[
\begin{align*}
(1.3) \quad & \int_{I_n} \{(U_t, \Phi) + (\mathcal{L}_h^t U, \Phi)\} \, dt = \int_{I_n} ((F_h(U), \Phi)) \, dt, \quad \forall \Phi \in V_{q-1} \times V_{q-1},
\end{align*}
\]
where \( U^0 = (u^0, u^1)^T \), and \( F_h(U) = (0, P^n f(U_1))^T \), \( P^n \) is the \( L^2 \) projection into \( S_h^n \) and \( \Pi^n \) denotes an appropriate projection operator into \( S_h^n \times S_h^n \). The analysis in this paper requires the choice \( \Pi^n = \begin{pmatrix} P^n_E & 0 \\ 0 & P^n \end{pmatrix} \), where \( P^n_E \) is the elliptic projection operator into \( S_h^n \). Note however that if \( S_h^{n-1} \subset S_h^n \), which would result if one refines the mesh locally, then \( U^{n+} = U^n \). Also, in practice, one could presumably use a Lagrangian type interpolation operator as a less expensive alternative to \( \Pi^n \). This will involve calculations only on the altered part of the mesh; cf. Remark 3.1 for a comment on the influence of this choice in the error analysis.

**Main results.** The convergence properties of this method are discussed in the next sections. To simplify the presentation, we assume here that \( f \) is globally Lipschitz; the general case of locally Lipschitz \( f \) can be treated as in [KM2]. Although we follow the basic ideas in [KM2], the approach taken here is different and does not follow with straightforward adaptations of the analysis in [KM2] for the nonlinear Schrödinger equation. One of the main difficulties presented here is the need to directly work with the energy norm. This requires special choices and more involved consistency analysis. On the other hand the analysis in this paper is more condensed and based rather on finite element type techniques compared with those of [KM1], [KM2].

In Theorem 3.1 we show that
\[
\begin{align*}
(1.4) \quad & \max_{t \in [0,T]} \left( \|u(t) - U_1(t)\| + \|u_t(t) - U_2(t)\| \right) \\
& \leq C \left\{ \max_n k_n^{2q+1} C_l(u) + \max_n h_n^r C_x(u) + \sqrt{N_C} \max_n \|J^n\| \right\},
\end{align*}
\]
where \( C_l(u) \) and \( C_x(u) \) are quantities depending on various temporal and spatial derivatives of \( u \), \( N_C \) denotes the number of times where \( S_h^j \neq S_h^{j-1} \), \( j = 1, \ldots, N - 1 \), and \( J^n = (\omega_n^{+} - \omega_n^{-}, \omega_n^{+} - \omega_n^{-})^T \) is the jump in the elliptic projection of \((u, u_t)^T \) at time \( t^n \) (cf. Theorem 3.1 for the details). Theorem 3.2 provides the “local” spatial mesh version of the estimate proved in Theorem 3.1. In addition a direct consequence of the estimates in the energy norm in Theorem 3.1 is the \( L^\infty \) estimate
\[
\begin{align*}
(1.5) \quad & \max_{t \in [0,T]} \|u(t) - U_1(t)\|_{\infty} \leq C L_h \left\{ \max_n k_n^{2q+1} C_l(u) + \max_n h_n^r C_x(u) + \sqrt{N_C} \max_n \|J^n\| \right\},
\end{align*}
\]
where \( L_h \) is a factor that grows logarithmically with \( h \). As in [KM2], an interesting feature in the proofs is the right choice of two time interpolating operators. These are the interpolants at the Gauss-Legendre (stability analysis) and at the Lobatto points of each \( I_n \) (consistency analysis). Note in addition that due to the mesh modification with \( n \) we have chosen to work with the energy norm, rather than with the weaker norm introduced in [BB] and used in [BL], [FP]. We show that we can retain the optimal order of convergence in the \( L^2 \) and \( L^\infty \) norms. See also [M] where this was done in a different context.
Note, however, the presence of the gradient in the jump terms due to the mesh modification (compare with [KM2]). Indeed, \( \|J^n\| = O(h^{-r-1}) \). In Section 4 we show that it is possible to eliminate the jump terms under the reasonable assumption that all meshes contain a reference mesh \( T_h \). Indeed, we show the optimal order estimate:

\[
(1.6) \quad \max_{t \in [0,T]} \left( \|u(t) - U_1(t)\| + \|u_t(t) - U_2(t)\| \right) \leq C \left( \max_n k^{q+1} c_n(u) + h^r c_x(u) \right).
\]

In particular this shows that optimal convergence rates can be retained when mesh modification is performed in many practical applications.

Finally, in Section 5 we show how to obtain increased accuracy for the jump terms under the assumption that the meshes differ only in a region of small area. In the two-dimensional case, and assuming that this region is of area \( \|J^0\| = O(h^r) \). Thus in this case also the convergence rates are optimal provided \( N_C \) remains bounded.

**Plan of the analysis.** The analysis in the forthcoming Sections 2 and 3 is based on several steps that we briefly describe. One of the main ingredients of our approach is the use of the connection of the continuous Galerkin method to the Runge-Kutta–Gauss-Legendre family. This connection is used as a motivation for the representation of \( U \) in terms of its values at the Gauss points of each \( I_n \) (cf. (2.3))

\[
U(x, t) = \sum_{j=0}^{q} \hat{e}_{n,j}(t)U^{n,j}(x), \quad (x, t) \in \Omega \times I_n, \quad t^{n,0} = t^n.
\]

Here \( t^{n,j} \), \( j = 1, \ldots, q \), are the Gauss Legendre points of \( I_n \) and \( \{\hat{e}_i\}_{i=0}^q \) are the Lagrange polynomials of degree \( q \) associated with the \( q+1 \) points \( t^{n,j} \), \( j = 1, \ldots, q \), plus the point \( t^{n,0} = t^n \). Here, of course, \( U^{n,0} = U^{n+1} = \Pi^n U \) is the given starting value. This representation is crucial throughout the paper. Its first use is in the uniqueness proof, Lemma 2.1 and Theorem 2.1: Indeed in view of (2.7) and Lemma 2.1 we can gain control of \( \sum_{j=0}^{q} \|U^{n,j}\|^2 \) by appropriate selection of the test function in (2.7). Then the existence-uniqueness follows by applying known arguments; cf., e.g., [KM2]. Essentially the same argument is used later in the stability analysis for the control of the \( L^2(I_n; L^2) \) norm of the error by using (2.4); cf. Lemma 3.4.

**Consistency analysis—the basic error equation.** The error is decomposed as \( U - u = (U - W) + (W - u) \), where \( W = (W_1, W_2)^T \in V_q \times V_q \). The choice of \( W \) is essential since it should be chosen such that \( W - u \) has the right order and in addition \( W \) has desirable consistency properties. This is achieved by the definition of the components of \( W \) through (3.6), (3.7). Note first that the definitions are based on the interpolation operator \( T^n_{L_q} \) at the \( q+1 \) Lobatto points of \( I_n \) and the elliptic projection operator, (3.1). Lobatto interpolation is important since it preserves continuity at both endpoints of the interval and its corresponding quadrature has the same accuracy as that of the Gauss rule with \( q \) points. A more natural choice for \( W_1 \) would be just \( W_1(x, t) = T^n_{L_q} \omega(x, t) \), but then (3.8) is not valid. It turns out that (3.8) is essential in the sequel in order to avoid “spatial” error terms in the first component of the right-hand side of (3.9), and therefore \( W_1 \) given by (3.7) has all the desirable properties. The approximation properties of \( (W_1, W_2) \) are established in part (ii) of Lemma 3.3. It remains to estimate \( E = U - W \). In view of the definition of the scheme and the properties of \( W \) we conclude in Lemma 3.2.
that $E$ satisfies the basic error equation (3.9). Then the consistency terms that appear in its right-hand side are estimated in Lemma 3.3(ii).

**Stability analysis—estimate of $E$.** Next, the basic error equation (3.9) will be the starting point to prove the final estimate for $E$. Notice that we choose to work with the energy norm $\|E\| = (\|\nabla E_1\|^2 + \|E_2\|^2)^{1/2}$. This norm is a natural choice for the wave equation; in [BL], [FP] the weaker $L^2 \times H^{-1}$-like norm introduced in [BH] was used. The choice of the energy norm is important since it allows us to handle the mesh modification in a proper way. Next, by selecting $\Phi = P_i^{n,q-1}A_h^n E$ in (3.9), we conclude the first estimate (3.23). It is evident now that an additional bound of $\|E\|_{L^2(I_n;L^2)}$ is needed. This is obtained in Lemma 3.4. Indeed as in [KM2], we will consider for $q \geq 1$, the Gauss-Legendre integration rule,

$$\int_0^1 g(\tau) d\tau \equiv \sum_{j=1}^q w_j g(\tau_j), \quad 0 < \tau_1 < \cdots < \tau_q < 1,$$

which is *exact for all polynomials of degree* $\leq 2q - 1$. Let $\{\ell_i\}_{i=1}^q$ be the Lagrange polynomials of degree $q - 1$ associated with the abscissas $\tau_1, \ldots, \tau_q$.

Using the linear transformation $t = t^n + \tau k_n$ that maps $[0,1]$ onto $T_n$, we adapt the quadrature rule (2.1) to the interval $T_n$ by defining its abscissas and weights as follows:

$$t^{n,i} = t^n + \tau_i k_n,$$
$$\ell_{n,i}(t) = \ell_i(\tau), \quad t = t^n + \tau k_n,$$
$$w_{n,i} = \int_{t^n}^{t^{n,i}} \ell_{n,i}(t) dt = k_n \int_0^1 \ell_i(\tau) d\tau = k_n w_i, \quad i = 1, \ldots, q.$$

We shall also use the Lagrange polynomials $\{\tilde{\ell}_i\}_{i=0}^q$ of degree $q$ associated with the $q + 1$ points $0 = \tau_0 < \tau_1 < \cdots < \tau_q$. In particular, $U|_{I_n}$ is determined by the functions $U^{n,j} \in S_h^n \times S_h^n$ ($U^{n,j} = U(x,t^n)\{x\in\Omega\}$) such that

$$U(x,t) = \sum_{j=0}^q \tilde{\ell}_{n,j}(t)U^{n,j}(x), \quad (x,t) \in \Omega \times I_n, \quad t^{n,0} = t^n,$$

where $U^{n,0} = U^{n+} = \Pi^n U^n$ is given.

In the sequel, the following equivalence of norms will be useful:

$$C_1 \left\{k_n \sum_{j=0}^q \|v^j\|^2\right\}^{1/2} \leq \|v\|_{L^2(I_n;L^2)} \leq C_2 \left\{k_n \sum_{j=0}^q \|v^j\|^2\right\}^{1/2}, \quad v \in V_q$$

2. Notation—preliminaries.

As in [KM2], we will consider for $q \geq 1$, the Gauss-Legendre integration rule,
where \( v = \sum_{j=0}^{q} \hat{\ell}_n,j v^j \in V^n_q \). This is a consequence of the \( L^\infty - L^2 \) inverse property

\[
\max_{I_n} |y(t)| \leq C_l k_n^{-1/2} \left( \int_{I_n} |y(t)|^2 dt \right)^{1/2}, \quad \forall y \in \mathbb{P}_q(I_n),
\]

and of the bound \( \int_{I_n} |\hat{\ell}_n,j(t)| dt \leq c k_n \).

We consider the \( L^2 \)-projection operator \( P^{n,q-1}_t : \mathbb{P}_q[q^n, q^{n+1}] \to \mathbb{P}_q^{-1}[q^n, q^{n+1}] \). Then (cf. [KM2])

\[
P_t^{n,q-1} = T_{GL}^{n,q-1},
\]

where \( T_{GL}^{n,q-1} \) is the Lagrange interpolation operator corresponding to the \( q \) Gauss-Legendre points \( q^n, \ldots, q^q \). This is indeed the case since for \( v \in \mathbb{P}_q[q^n, q^{n+1}] \),

\[
\int_{I_n} (T_{GL}^{n,q-1} v) \phi dt = \sum_{j=1}^{q} w_{n,j} v(t^{n,j}) \phi(t^{n,j}) = \int_{I_n} v \phi dt, \quad \forall \phi \in \mathbb{P}_q^{-1}[q^n, q^{n+1}].
\]

Now, for \( \Phi \in V^n_q \times V^n_q \),

\[
\int_{I_n} ((U_t, \Phi)) = \sum_{i,j=1}^{q} m_{ij} ((U^n_{i,j}, \Phi^i) + \sum_{i=1}^{q} m_{i0} ((U^n, \Phi^i)),
\]

with

\[
m_{ij} = \int_{I_n} \hat{\ell}_n,j(t) \hat{\ell}_n,i(t) dt, \quad i = 1, \ldots, q, \quad j = 0, \ldots, q,
\]

and \( v^i = v(t^{n,i}) \). The stability of the method relies on the positivity of the matrix \( \mathcal{M} \)

\[
\mathcal{M}_{ij} = m_{ij}, \quad i, j = 1, \ldots, q.
\]

In fact it is shown in [KM2] that the array \( \widehat{\mathcal{M}} = D^{-1/2} \mathcal{M} D^{1/2} \), where \( D = \text{diag}\{\tau_1, \ldots, \tau_q\} \) is positive definite:

**Lemma 2.1** ([KM2]). Let \( \alpha := \frac{1}{q} \min_j \frac{w_j}{\tau_j} \). Then

\[
x^T \widehat{\mathcal{M}} x \geq \alpha |x|^2 = \alpha \left( \sum_{i=1}^{q} x_i^2 \right), \quad \forall x \in \mathbb{R}^q.
\]

Employing then similar arguments as in [KM2], we get the existence and uniqueness of the numerical approximations.

**Theorem 2.1.** Let \( U^n \) be given in \( S_h^{n-1} \times S_h^{n-1} \). Then for \( k_n \) sufficiently small there exists a unique solution \( U \in V_q^n \times V_q^n \) of equation (1.3).

### 3. Error estimates

We split the error \( U - u = (U - W) + (W - u) \), where \( W \in V_q^n \times V_q^n \) will be defined below, and we estimate \( E = U - W \) and \( u - W \). To define \( W \), we consider the elliptic projection operator \( P^n_E : H^1_0(\Omega) \to S_h^n \) defined as usual by

\[
(\nabla P^n_E v, \nabla \chi) = (\nabla v, \nabla \chi), \quad \forall \chi \in S_h^n.
\]

We assume that the family of spaces \( S_h^n \) satisfies

\[
\| \nabla (v - P^n_E v) \| \leq c h^{s-1}_n \| v \|_s, \quad v \in H^s \cap H^1_0, \quad 2 \leq s \leq r,
\]
and

\[ \|v - P^n_E v\| \leq c h^n_s \|v\|, \quad v \in H^s \cap H^1_0, \quad 2 \leq s \leq r, \]

where \( c \) is independent of \( n \).

See [BO], [EJ], [BS Chapter 0], and [KM1] for a discussion on these assumptions.

We will also need a temporal interpolation operator: As in [KM2] we consider interpolation at Gauss-Lobatto points. For this let \( 0 = \xi_0 < \cdots < \xi_q = 1 \) be the \( q + 1 \) roots of the polynomial \( L(x) = \frac{d^{q-1}}{dx^{q-1}}[x(1-x)]^q \). The corresponding Gauss-Lobatto quadrature rule, [BS],

\[ \int_0^1 g(\tau) \, d\tau \approx \sum_{j=0}^q b_j g(\xi_j), \]

is exact on \( \mathbb{P}_{2q-1} \). As done with the Gauss-Legendre points, we can define the weights \( b_{n,j} \) corresponding to the interval \( I_n \). In addition let \( I^n_{\text{Lo}} \) be the Lagrange interpolation operator at the \( q + 1 \) Lobatto points \( t^n = \xi^{n,j} < \cdots < \xi^{n,q} = t^{n+1} \).

We define \( \omega \) and \( \eta \) by

\[ \omega(x, t) = P^n_E u(x, t), \quad \eta = u - \omega, \quad (x, t) \in \Omega \times I_n, \quad n = 0, \ldots, N - 1. \]

We next define \( W = (W_1, W_2) \). First let

\[ W_2(x, t)\big|_{I_n} = I^n_{\text{Lo}} \omega_1(x, t), \quad W_2(t^0) = P^0_E u^1, \]

and then,

\[ W_1\big|_{I_n} = I^n_{\text{Lo}} \left( \int_{t^n}^t W_2 \, dt + \omega^{n+} \right). \]

We have

**Lemma 3.1.** It holds that

\[ \int_{I_n} (W_1, t, \varphi) \, dt = \int_{I_n} (W_2, \varphi) \, dt, \quad \forall \varphi \in V_{q-1}. \]

**Proof.** Let \( Z\big|_{I_n} = \int_{t^n}^t W_2 \, dt + \omega^{n+} \). Then \( W_1\big|_{I_n} = I^n_{\text{Lo}} Z \). Using the definition of \( I^n_{\text{Lo}} \) and the exactness of the Gauss-Lobatto integration rule, we get

\[
\int_{I_n} (W_1, t, \varphi) \, dt = - \int_{I_n} (W_1, \varphi_t) \, dt + (Z, \varphi)(t^{n+1}) - (Z, \varphi)(t^{n+})
= - \sum_{j=0}^q b_{n,j} (Z, \varphi_t)(\xi^{n,j}) + (Z, \varphi)(t^{n+1}) - (Z, \varphi)(t^{n+})
= - \int_{I_n} (Z, \varphi_t) \, dt + (Z, \varphi)(t^{n+1}) - (Z, \varphi)(t^{n+})
= \int_{I_n} (Z_t, \varphi) \, dt = \int_{I_n} (W_2, \varphi) \, dt,
\]

since \( (Z, \varphi_t) \in \mathbb{P}_{2q-1} \).
The basic error equation.

Lemma 3.2. Let \( E = E|_{t_n} = U - W \) and

\[
A^n_I := \mathcal{I}^{n,q}_{L_0} \left( \int_{t_n}^t (I - \mathcal{I}^{n,q}_{L_0}) u_t \, ds \right),
\]
\[
A^n_{\mathcal{B}} := u_{tt} - W_{2,t},
\]
\[
A^n_{\mathcal{B}' := f(W_1) - f(u) + (\mathcal{I}^{n,q}_{L_0} - I) \Delta u.
\]

Then for all \( \Phi = (\phi_1, \phi_2)^T \in V^{n}_{q-1} \times V^{n}_{q-1} \) and \( n = 0, 1, \ldots, N - 1 \),

\[
\int_{I_n} ((E_l + \mathcal{L}^n_{h} E, \Phi)) \, dt = \int_{I_n} \{(f(U_1) - f(U_2), \phi_1) - (\Delta A^n_I, \phi_2) + (A^n_{\mathcal{B}} + A^n_{\mathcal{B}'}, \phi_2)\} \, dt.
\]

Proof. To begin, \( E \) satisfies

\[
\int_{I_n} ((E_l + \mathcal{L}^n_{h} E, \Phi)) \, dt = \int_{I_n} \{(F_h(U, \Phi)) - ((W_l + \mathcal{L}^n_{h} W, \Phi))\} \, dt.
\]

Also note that \( (F_h(U, \Phi)) = (f(U_1), \phi_2) \). On the other hand, by Lemma 3.1 we have

\[
\int_{I_n} ((W_l + \mathcal{L}^n_{h} W, \Phi)) \, dt = \int_{I_n} \{(W_{1,t} - W_2, \phi_1) + (W_{2,t}, \phi_2) + (\nabla W_1, \nabla \phi_2)\} \, dt
\]
\[
= \int_{I_n} (W_{2,t}, \phi_2) \, dt + \int_{I_n} (\nabla W_1, \nabla \phi_2) \, dt.
\]

By the definition of \( W_1 \) and (1.1) we obtain

\[
\int_{I_n} (\nabla W_1, \nabla \phi_2) \, dt = \sum_{j=0}^{q} b_{n,j}(\nabla Z, \nabla \phi_2)(\xi^{n,j})
\]
\[
= \sum_{j=0}^{q} b_{n,j}(\nabla (\int_{I_n}^{\xi^{n,j}} u_t ds + u^n), \nabla \phi_2(\xi^{n,j}))
\]
\[
= \int_{I_n} (\Delta A^n_I, \phi_2) + \sum_{j=0}^{q} b_{n,j}(\nabla (\int_{I_n}^{\xi^{n,j}} u_t ds + u^n), \nabla \phi_2(\xi^{n,j}))
\]
\[
= \int_{I_n} (\Delta A^n_I, \phi_2) + \sum_{j=0}^{q} b_{n,j}(\nabla \phi_2(\xi^{n,j}), \nabla \phi_2(\xi^{n,j}))
\]
\[
= \int_{I_n} (\Delta A^n_{\mathcal{B}}, \phi_2) + \int_{I_n} (\nabla u, \nabla \phi_2) + \int_{I_n} (\nabla (\mathcal{I}^{n,q}_{L_0} u - u), \nabla \phi_2)
\]
\[
= \int_{I_n} (\Delta A^n_{\mathcal{B}}, \phi_2) + \int_{I_n} (f(u), \phi_2) - \int_{I_n} (u_{tt}, \phi_2) - \int_{I_n} ((\mathcal{I}^{n,q}_{L_0} - I) \Delta u, \phi_2),
\]

and the proof is complete.

In the next lemma we show that indeed \( W_1 \) and \( W_2 \) have the right approximation properties and we estimate \( A^n_I, A^n_{\mathcal{B}}, A^n_{\mathcal{B}'} \).
We begin by proving a stability property of the Lobatto interpolation operator $c$.

This in turn gives the required stability result in the $I$.

\begin{equation}
\|W_2 - u_t\|_{L^p(I_n;L^2)} \leq c n^{q+1} \|u(t)\|_{L^p(I_n;L^2)} + c n^q \|u(t)\|_{L^p(I_n;H^r)}
\end{equation}

Proof. \((3.14)\)

We shall also use the inequality \((3.19)\). From \((3.15)\) and \((3.16)\) it follows that

\begin{equation}
\|T^{n,q}_{L_0} \phi\|_{L^2(I_n;L^2)} \leq c \|\phi\|_{L^2(I_n;L^2)} + c n \|\phi\|_{L^2(I_n;L^2)}.
\end{equation}

We shall also use the inequality

\begin{equation}
\|\phi\|_{L^2(I_n;L^2)} \leq c n \|\phi\|_{L^2(I_n;L^2)}, \quad \text{where } \phi = \int_{t_n}^t \psi \, ds.
\end{equation}

Write $W_1 - u = T^{n,q}_{L_0} \int_{t_n}^t (W_2 - \omega_t) \, ds + T^{n,q}_{L_0} \omega - u$. From \((3.15)\) and \((3.16)\) it follows that

\begin{equation}
\|T^{n,q}_{L_0} \int_{t_n}^t (W_2 - \omega_t) \, ds\|_{L^2(I_n;L^2)} \leq c n \|W_2 - \omega_t\|_{L^2(I_n;L^2)}.
\end{equation}

Now, $W_2 - \omega_t = T^{n,q}_{L_0} \omega_t - \omega_t = -T^{n,q}_{L_0} \eta_t - (u_t - T^{n,q}_{L_0} u_t) - \eta_t$. From \((3.15)\),

\begin{equation}
\|T^{n,q}_{L_0} \eta_t\|_{L^2(I_n;L^2)} + \|\eta_t\|_{L^2(I_n;L^2)} \leq c \|\eta_t\|_{L^2(I_n;L^2)} + c n \|\eta_t\|_{L^2(I_n;L^2)}
\end{equation}

The approximation properties of the operator $T^{n,q}_{L_0}$ give

\begin{equation}
\|u_t - T^{n,q}_{L_0} u_t\|_{L^2(I_n;L^2)} \leq c n^{q+1} \|u(t)\|_{L^2(I_n;L^2)}.
\end{equation}

Writing $T^{n,q}_{L_0} \omega - u - \omega_t = -T^{n,q}_{L_0} \eta + T^{n,q}_{L_0} u - u$, as above we obtain

\begin{equation}
\|T^{n,q}_{L_0} \omega - u\|_{L^2(I_n;L^2)} \leq c n \|u\|_{L^2(I_n;L^2)} + c n^{q+1} \|u(t)\|_{L^2(I_n;L^2)}.
\end{equation}

Inequality \((3.10)\) now follows from \((3.17)-(3.20)\). Similarly, writing $u_t - W_2 = u_t - T^{n,q}_{L_0} u_t + T^{n,q}_{L_0} \eta_t$, we see that \((3.11)\) follows from \((3.18)-(3.19)\).
(ii) We next estimate \( \|\Delta A^p_t\|_{L^2(I_n;L^2)} \). From (3.15) and (3.16)
\[
\|\Delta A^p_t\|_{L^2(I_n;L^2)} = \|T^{n,q}_{I_0} \int_{I_n} (I - T^{n,q}_{I_0}) \Delta u_t \, ds\|_{L^2(I_n;L^2)} \\
\leq c_k n \| (I - T^{n,q}_{I_0}) \Delta u_t \|_{L^2(I_n;L^2)} \\
\leq c_k n^{q+1} \|\Delta u^{(q+1)}\|_{L^2(I_n;L^2)}.
\]
Also,
\[
\|A^p_n\|_{L^2(I_n;L^2)} \leq \|f(W_1) - f(u)\|_{L^2(I_n;L^2)} + \| (I - T^{n,q}_{I_0}) \Delta u \|_{L^2(I_n;L^2)} \\
\leq c \|W_1 - u\|_{L^2(I_n;L^2)} + Ck_n^{q+1} \|\Delta u^{(q+1)}\|_{L^2(I_n;L^2)}.
\]

It remains to estimate \( A^p_n \). Let \( \varphi \in V_{q-1} \). Then \( \eta_t = u_t - \omega_t \)
\[
\int_{I_n} (A^p_n, \varphi) dt = \int_{I_n} (u_{tt} - (T^{n,q}_{I_0} u_t), \varphi) dt + \int_{I_n} ((T^{n,q}_{I_0} \eta_t), \varphi) dt =: \Gamma_1 + \Gamma_2.
\]
To estimate \( \Gamma_1 \), we have since the endpoints of \( I_n \) are included in the Lobatto points
\[
\Gamma_1 = \int_{I_n} (u_{tt} - (T^{n,q}_{I_0} u_t), \varphi) dt = - \int_{I_n} (u_t - T^{n,q}_{I_0} u_t, \varphi_t) dt.
\]
We next let \( T^{n,q+1} \) denote the Lagrange interpolation operator at the \( q + 2 \) points of \([t^n, t^{n+1}]\) consisting of the \( q + 1 \) Lobatto points \( \xi^n_0, \ldots, \xi^n_q \) and any number in \([t^n, t^{n+1}]\) distinct from the above, e.g., the average of any two adjacent Lobatto points. Then, \( (T^{n,q+1} u_t) \varphi_t \) is a polynomial of degree \( 2q - 1 \) in \( t \) and we thus obtain
\[
\int_{I_n} (u_t - T^{n,q}_{I_0} u_t, \varphi_t) dt = \int_{I_n} (u_t - T^{n,q+1} u_t, \varphi_t) dt.
\]
Integrating by parts, we finally get
\[
|\Gamma_1| = |\int_{I_n} [(u_t - T^{n,q+1} u_t)_t, \varphi] dt| \\
\leq Ck_n^{q+1} \|u^{(q+3)}\|_{L^2(I_n;L^2)} \|\varphi\|_{L^2(I_n;L^2)}.
\]
Now viewing \( \eta_t(t^{n+1}) \) as a function constant in time,
\[
\Gamma_2 = \int_{I_n} (T^{n,q}_{I_0} [\eta_t - \eta_t(t^{n+1})], \varphi) dt = \int_{I_n} (T^{n,q}_{I_0} [\int_{t^n}^t \eta_t], \varphi).
\]
Using an \( H^1 \)-\( L^2 \) inverse property (similar to (2.5)), we obtain
\[
|\Gamma_2| \leq c k_n^{-1} \|T^{n,q}_{I_0} [\int_{t^n}^t \eta_t]\|_{L^2(I_n;L^2)} \|\varphi\|_{L^2(I_n;L^2)}.
\]
Inequality (3.13) now follows from (3.15) and (3.16). The proof of the lemma is complete.

**Stability.** Our intention is to derive estimates for \( \|E\| = (\|\nabla E_1\|^2 + \|E_2\|^2)^{1/2} \).
For this, we take \( \Phi = P^{n,q-1}_{t} A^p E \in V_{q-1} \times V_{q-1} \) in (3.9), where
\[
P_{t}^{n,q-1} = \begin{pmatrix} P_{t}^{n,q-1} & 0 \\ 0 & P_{t}^{n,q-1} \end{pmatrix} \quad \text{and} \quad A^p E = \begin{pmatrix} A^p E_1 \\ A^p E_2 \end{pmatrix}.
\]
Then clearly,
\[
(3.21) \quad \int_{I_n} ((E_t, \Phi)) dt = \frac{1}{2} \|E^{n+1}\|^2 - \frac{1}{2} \|E^n\|^2.
\]
We then choose in (3.9)  
\[ \int_{I_n} ((L^n_h E, P^{n,q-1}_h A^n_h E)) dt = \sum_{j=1}^q w_{n,j} ((L^n_h E, A^n_h E)) (t^{n-j}) = 0. \]

As for the right-hand side of (3.9), note that only \( \phi_2 = P^{n,q-1}_h E_2 \) appears. Since \( f \) is Lipschitz, the first term is bounded by \( c \| E_1 \|_{L^2(I_n;L^2)} \| E_2 \|_{L^2(I_n;L^2)} \) and hence by \( c \| \nabla E_1 \|_{L^2(I_n;L^2)} \| E_2 \|_{L^2(I_n;L^2)} \) via Poincaré’s inequality. The remaining terms having been estimated in Lemma 3.3 (estimates (3.12)–(3.14)), from (3.21) and (3.22) it follows that for \( n = 0, \ldots, N - 1 \),

\[ \| E^{n+1} \|^2 \leq \| E^n \|^2 + c \| E \|_{L^2(I_n;L^2)}^2 + c \left( k_n^{q+1} E_t^n + c h_n E_{xx}^n \right)^2, \]

where

\[ E^n_t = E^n_t(u, q) = \| u^{(q+1)} | + u^{(q+2)} | + u^{(q+3)} | + | \nabla u^{(q+2)} | + | \Delta u^{(q+1)} \|_{L^2(I_n;L^2)}, \]

\[ E^n_x = E^n_x(u, r) = \| u | + | u_t | + | u_{tt} \|_{L^2(I_n;H^r)}. \]

We have used this particular presentation of \( E^n_t(u, q) \) and \( E^n_x(u, r) \) for brevity. We have also included the term \( \nabla u^{q+2} \) in anticipation of the term \( B_{n-1} \) that will appear in Lemma 3.5.

We next estimate the term \( \| E \|_{L^2(I_n;L^2)} \) in (3.23)

**Lemma 3.4.** For any \( n, 0 \leq n \leq N - 1 \), and \( k_n \) sufficiently small, it holds that

\[ \| E \|_{L^2(I_n;L^2)}^2 \leq c k_n \| E^n \|^2 + c k_n \left( k_n^{q+1} E_t^n + c h_n E_{xx}^n \right)^2. \]

**Proof.** Let \( \bar{E}^{n,j} = \tau_j^{-1/2} E^{n,j}, j = 1, \ldots, q \). Recalling that \( E^{n,0} = E^n \), we have

\[ E(x,t) = \sum_{j=0}^q \hat{E}_{n,j}(t) E^{n,j}(x) = \sum_{j=1}^q \hat{E}_{n,j}(t) \tau_j^{-1/2} \bar{E}^{n,j}(x) + \hat{E}_{n,0}(t) E^n(x). \]

We then choose in (3.9) \( \Phi = \Phi_E := \sum_{i=1}^q \ell_i \hat{E}_{n,i}(t) \tau_i^{-1/2} A^n_h \bar{E}^{n,i} \). As in (3.22)

\[ \int_{I_n} ((L^n_h E, \Phi_E)) = \sum_{j=1}^q w_{n,j} \tau_j^{-1} ((L^n_h E^{n,j}, A^n_h E^{n,j})) = 0. \]

Also, using (2.7) and Lemma 2.1

\[ \int_{I_n} ((E_t, \Phi_E)) dt = \sum_{i,j=1}^q m_{ij} [\nabla \bar{E}^{n,j}_1, \nabla \bar{E}^{n,i}_1] + (\bar{E}^{n,j}_2, \bar{E}^{n,i}_2) \]

\[ + \sum_{i=1}^q m_{i0} \tau_i^{-1/2} [\nabla \bar{E}^{n,i}_1, \nabla \bar{E}^{n,i}_1] + (\bar{E}^{n,i}_2, \bar{E}^{n,i}_2) \]

\[ \geq c \sum_{j=1}^q \| \bar{E}^{n,j} \|^2 - c \left( \sum_{j=1}^q \| \bar{E}^{n,j} \|^2 \right)^{1/2} \| E^n \|. \]

The quantities (norms) \( \sum_{j=1}^q \| \bar{E}^{n,j} \|^2 \) and \( \sum_{j=1}^q \| E^{n,j} \|^2 \) are equivalent modulo constants that depend only on the \( \tau_i \)’s. Similarly, it is easily seen (cf. [KM2]) that
the quantities $\sum_{j=0}^{q} \|E^{n,j}\|^2$ and $\|E\|^2_{L^2(I_n;L^2)}$ are equivalent in the sense that

$$ck_n \sum_{j=0}^{q} \|E^{n,j}\|^2 \leq \|E\|^2_{L^2(I_n;L^2)} \leq c_2k_n \sum_{j=0}^{q} \|E^{n,j}\|^2.$$  (3.26)

The terms on the right side of (3.9) with $\Phi = \Phi_E$ can be estimated just as before. This and (3.25), (3.26) imply (3.24).  

We proceed to estimate $\|E^{n+}\|^2$ which appears both in (3.23) and (3.24). Let $M_n \geq 2$ be a number depending on $n$ which will be specified in the sequel and

$$\beta_n = \frac{\gamma_n}{M_n - 1}, \quad \gamma_n = \begin{cases} 0 & \text{if } S^n_h = S^{n-1}_h, \\ 1 & \text{otherwise}, \end{cases}, \quad n = 1, \ldots, N - 1.$$

**Lemma 3.5.** For any $n$, $1 \leq n \leq N - 1$, it holds that

$$\|E^{n+}\|^2 \leq (1 + \beta_n + k_{n-1})\|E^n\|^2 + \gamma_n(M_n + k_{n-1})\|J^n\|^2 + cB^2_{n-1}$$  (3.27)

where

$$\|J^n\|^2 = \|\nabla(\omega^{n+} - \omega^n)\|^2 + \|\omega^{n+}_t - \omega^n_t\|^2$$

and

$$B_{n-1} \leq ck_{n-1}^q \|u(q+2)\|_{L^2(I_{n-1};L^2)}.$$

**Proof.** We first consider the term $\|E^{n+}_2\|$. Then,

$$\|E^{n+}_2\| = \|U^{n+}_2 - W^{n+}_2\| = \|P^n E^n_2 - P^n [\omega^{n+}_t - \omega^n_t]\|$$

$$\leq \|E^n_2\| + \|\omega^{n+}_t - \omega^n_t\|.$$  (3.28)

Next for $\|\nabla E^{n+}_1\|$ we have

$$\|\nabla E^{n+}_1\| = \|\nabla(P^n E^n_1 - W^{n+}_1)\|$$

$$\leq \|\nabla P^n E^n_1 - W^{n+}_1\| + \|\nabla P^n_1(W^n_1 - W^{n+}_1)\|$$

$$\leq \|\nabla(U^n_1 - W^{n+}_1)\| + \|\nabla(W^{n+}_1 - W^n_1)\|.$$  (3.29)

Now using the definition of $W_1$ we have

$$\|\nabla(W^{n+}_1 - W^n_1)\|$$

$$\leq \|\nabla(W^{n+}_1 - P^n E^n_1 u^n)\| + \|\nabla P^n E^n_1(u^n - \int_{t_{n-1}}^{t_{n}} T_{Lo}^{n-1} a u_t dt - u^{n-1})\|$$

$$\leq \|\nabla(P^n_1 - P^n E^n_1) u^n\| + \|\nabla(u^n - \int_{t_{n-1}}^{t_{n}} T_{Lo}^{n-1} a u_t dt - u^{n-1})\|$$

$$= \|\nabla(\omega^{n+} - \omega^n)\| + \|\int_{t_{n-1}}^{t_{n}} (I - T_{Lo}^{n-1} a) \nabla u_t\|$$

$$\leq \|\nabla(\omega^{n+} - \omega^n)\| + ck_{n-1} B_{n-1}.$$  (3.30)

The result now follows from (3.28)–(3.30) and applications of the arithmetic geometric mean inequality.  

We note here that unlike the term $J(\zeta^n)$, $B_{n-1}$ is nonzero in general even if the spaces $S^n_h$ and $S^{n-1}_h$ are the same.
Remark 3.1. The choice $\Pi^n = \begin{pmatrix} P^n_E & 0 \\ 0 & P^n \end{pmatrix}$ in (1.3) was used in an essential way in Lemma 3.5. Indeed in (3.28) and (3.29) we used the natural stability of $P^n$ and $P^n_E$ in $L^2$ norm and $H^1$ seminorm, respectively. A more convenient choice in practice would be to use a Lagrangian type interpolation operator. In that case we would have $U^{n+1} = \Pi^n U^n = \begin{pmatrix} \Pi^n_h & 0 \\ 0 & \Pi^n \end{pmatrix} U^n$, where $\Pi^n_h$ is the standard interpolation operator into $S^n_h$. Then the result of Lemma 3.5 would still be valid provided

$$
(A1) \quad \|\Pi^n E^n\| \leq (1 + C k_n)\|E^n\| \quad \text{and} \quad \|\nabla \Pi^n E^n\| \leq (1 + C k_n)\|\nabla E^n\|.
$$

Of course there are no guarantees that these bounds are valid. To retain the convergence result we could impose (A1) as an extra assumption. On the other hand (A1) might be satisfied in practice when the mesh adaptation is performed under a reasonable adaptive strategy. Indeed the influence of $\Pi^n_h$ is local. The alteration of the mesh will normally consist on the part where we refine and the part where the mesh is coarsened. $\Pi^n E^n$ differs from $E^n$ only in the coarsened area. But a reasonable adaptive algorithm chooses to coarsen the mesh only in areas where the error is well below a given tolerance and without strong variations. Therefore although (A1) is an extraneous condition that cannot be justified a priori, its validity might be within reason in successful adaptive computations.

We are now ready to prove the main convergence result for our scheme.

**Theorem 3.1.** Let $u$ and $U$ be the solutions of (1.1) and (1.3), respectively. Then

$$
\max_{t \in [0,T]} \|E\| \leq c \sum_{n=0}^{N-1} e^{c(T-t_n)} \left\{ k_n^{q+1} \varepsilon_{t}^{n} + h_n^{r} \varepsilon_{x}^{n} \right\} + c e^{cT} N_C \max_{n} \|J^n\|,
$$

where $N_C$ denotes the number of times where $S^n_h \neq S^{n-1}_h$, $j = 1, \ldots, N - 1$. In addition, (1.4) and (1.5) hold.

**Proof.** To begin, note that $E^0 = (0, (P^0 - P^0_E) u^1)^T$. Hence, $\|E^0\| \leq c h^{r} \varepsilon_{x}^{0}$. Also, (3.23), (3.24) and (3.27) imply (set $B_{-1} = B_0$ and $E^0 = E^{0+}$)

$$
\|E^{n+1}\| \leq (1 + c k_n) \left\{ (1 + \beta_n + k_{n-1}) \|E^n\| + \gamma_n (M_n + k_{n-1}) \|J^n\| + c B_{n-1}^2 \right\}
+ c (1 + c k_n) \left( k_n^{q+1} \varepsilon_{t}^{n} + h_n^{r} \varepsilon_{x}^{n} \right)^2, \quad n = 0, \ldots, N - 1.
$$

A standard Gronwall type argument gives

$$
\|E^n\|^2 \leq c \sum_{m=0}^{n-1} C_{m,n-1} \left\{ (k_m^{q+1} \varepsilon_{t}^{m} + h_m^{r} \varepsilon_{x}^{m})^2 + \gamma_m (M_m + k_{m-1}) \|J^n\|^2 \right\}, \quad n = 1, \ldots, N,
$$

where $C_{m,n-1} = \prod_{j=m}^{n-1} (1 + c k_j)(1 + \beta_j + k_{j-1})$. We shall next estimate these terms.
We fix \( n \) and choose \( M_m = M = N_C(n-1) + 1 \), \( m = 1, \ldots, n-1 \), where \( N_C(n-1) \) denotes the number of times where \( S^j_h \neq S_{j-1}^h \), \( j = 1, \ldots, n-1 \). Then, \( \beta_j = \beta = \frac{1}{M-1} \), whenever \( S^j_h \neq S_{j-1}^h \), and \( \beta_j = 0 \) otherwise. Thus, for \( m \leq \ell \leq n-1 \),
\[
C_{m,n-1} \leq \prod_{j=m}^{n-1} (1 + ck_j) \prod_{j=m}^{n-1} (1 + 2k_{j-1}) \prod_{j=m}^{n-1} (1 + 2\beta) \\
\leq e^{c(t_n-t_m)} \cdot e^{2(t_n-t_m-1)} \cdot (1 + 2\beta)^{M-1} \leq e^{c(t_n-t_m-1)} \cdot e^2.
\]
Using this in (3.32), we obtain
\[
\max_{1 \leq n \leq N} \|E^n\|^2 \leq c \sum_{n=0}^{N-1} e^{c(T-t_n)} \left( k_n^q \xi^n_1 + h_n^r \xi^n_2 \right)^2 + ce^{cT}N_C \max_{n} \|J^n\|^2.
\]
Inequality (3.31) now follows from the inverse inequality (2.5), (3.24), (3.27) and (3.33). Now (1.4) follows from (3.31) upon using the triangle inequality (recall that \( U - \left( \begin{array}{l} u \\ u_t \end{array} \right) = E + W - \left( \begin{array}{l} u \\ u_t \end{array} \right) \)), Poincaré’s inequality on the first component of \( E \) and the consistency estimates of Lemma (3.3) ((3.10) and (3.11) with \( p = \infty \)). Finally, (1.5) can be obtained by making use of a well-known \( H^1-L^\infty \) inverse inequality that holds in 2 dimensions (cf. [Thomee] p. 67).

Estimates with local spatial mesh sizes. In the previous estimates we did not work with the local mesh sizes, but rather with the global \( h \). The results are extended in the local mesh form provided we assume that the elliptic projection operator \( P^h_E : H^1_0(\Omega) \rightarrow S^h_0 \) defined in (3.1) satisfies the “local mesh” versions of (3.2), (3.3); i.e., we assume that
\[
\|\nabla(v - P^h_E v)\| \leq c \|h^{s-1}_n v\|, \quad v \in H^s \cap H^1_0, \ 2 \leq s \leq r,
\]
and
\[
\|v - P^h_E v\| \leq c \|h^s_n v\|, \quad v \in H^s \cap H^1_0, \ 2 \leq s \leq r,
\]
where \( c \) is independent of \( n \). Here we use the “local mesh” notation
\[
\|h^s_n v\|_m = \left\{ \sum_{K \in T_{hn}} h^{2s}_K \|v\|_{m,K}^2 \right\}^{1/2},
\]
and \( \|v\|_{m,K} \) denotes the restriction of the Sobolev norm to \( K \). Clearly the estimate (3.34) is straightforward. Inequality (3.35) requires more care. Indeed, it is known that (3.35) is valid in one dimension without any assumptions on the mesh; cf. [BO]. In higher dimensions (3.35) is valid under appropriate local quasiuniformity conditions; cf. [EJ] and the references therein and also [BS] Chapter 0 for a discussion of the one-dimensional case that hints at the difficulties of the problem. Essentially (3.35) is used only to bound the “elliptic” consistency terms in Lemma 3.3. Therefore Theorem 3.1 still holds if we replace the \( h^n_0 \|v\|_r \)-like terms by corresponding terms involving the error of the elliptic projection in the \( L^2 \)-norm. We can thus obtain by entirely similar arguments
Theorem 3.2. Let $u$ and $U$ be the solutions of (1.1) and (1.3), respectively. Then
\begin{equation}
(3.36) \quad \max_{t \in [0,T]} \|E\| \leq c \sum_{n=0}^{N-1} e^{c(T-t_n)} \left\{ k_n^{q+1} E_n^1 + K_{n}^{n}(h^{r}_n) \right\} + ce^{cT} \sqrt{N_C} \max_{n} \|J^n\|,
\end{equation}
where $N_C$ denotes the number of times where $S^n_{h} \neq S^{n-1}_{h}$, $j = 1, \ldots, N - 1$, and
\[ K_{n}^{n}(h^{r}_n) = \|h^{r}_n(u) + |u_{t}| + |u_{tt}|\|_{L^2(\Omega,h^{r})}. \]

In addition, the local mesh version of (1.4) holds. The $L^\infty$ estimate requires a local mesh estimate of the elliptic projection in the $L^\infty$ norm:
\[ \|v - P_{E_{h}}v\|_{\infty} \leq c\|h^{r}_{n}v\|_{r,\infty}; \]
cf., e.g., [E], [SW] and their references.

4. Estimates under conditions on the mesh

We will assume in this section that the meshes in each time step are generated by a reference (coarse) mesh $T_h$. In particular starting with $T_h$ we may want to refine the mesh in a part of the domain after some time steps. Then (since we may want to capture a moving singularity) we may choose to redefine in this area (and thus getting the original partition there) and to refine in a new area. This situation can be summarized by assuming that a fixed space $S_h$, that corresponds to the reference mesh $T_h$, is a subspace of all the finite element spaces $S^n_{h}$. We denote $h = \max_{K \in T_h} h_K$, and we assume that
\begin{equation}
(4.1) \quad \inf_{\varphi \in S_h} \|v - \varphi\|_s \leq C h^{r-s} \|v\|_r, \quad s = 0, 1.
\end{equation}

The main idea in this section is that although $U^n$ lies in a different space $S^n_{h}$ for each $n$, we will compare it with a function (denoted again) $W$ such that $W(t) \in S_h$ for all $t$. For this we split the error as $U - (u, u_{t})^T = (U - W) + (W - (u, u_{t})^T)$. To define $W$, we consider the elliptic projection operator $P_{E_{h}} : H^1_{0}(\Omega) \rightarrow S_h$ defined by
\begin{equation}
(4.2) \quad (\nabla P_{E_{h}}v, \nabla \chi) = (\nabla v, \nabla \chi), \quad \forall \chi \in S_h.
\end{equation}

Then $P_{E_{h}}$ satisfies the well-known estimates
\begin{equation}
(4.3) \quad \|\nabla (v - P_{E_{h}}v)\| \leq c h^{r-1} \|v\|_s, \quad \|v - P_{E_{h}}v\| \leq c h^{s} \|v\|_s, \quad v \in H^s \cap H^1_{0}, \quad 2 \leq s \leq r.
\end{equation}

We define $\tilde{\omega}, \tilde{\eta}$ as
\[ \tilde{\omega}(x, t) = P_{E_{h}}u(x, t), \quad \tilde{\eta} = u - \tilde{\omega}. \]

If $W = (W_1, W_2)|_{I_n}$, we let
\[ W_2|_{I_n} = \mathcal{I}_{\text{Lo}}^{n,q} \tilde{\omega}_t, \quad W_1|_{I_n} = \mathcal{I}_{\text{Lo}}^{n,q} \left( \int_{t_n}^{t} W_2 \ dt + \tilde{\omega}^n \right). \]

(Note that $\tilde{\omega}^n = \tilde{\omega}^n$..) Then the relation
\[ \int_{I_n} (W_1, \varphi) dt = \int_{I_n} (W_2, \varphi) dt \quad \text{for all } \varphi \in V_{q-1} \]
still holds.

The analysis then is the same as in Section 3. The main difference is that in the place of Lemma 3.4 we now have
Lemma 4.1. It holds that
\[ \|E^{n+}\| \leq \|E^n\| + G^n \]
where
\[ G^n \leq c k_{n-1}^{1/2} k_{n-1}^{q+1} \|\nabla u^{(q+2)}\|_{L^2(I_{n-1};L^2)}. \]

Proof. We first consider the term \( \|E_2^{n+}\| \). Then,
\[ E_2^{n+} = U_2^{n+} - W_2^{n+} = P_{E_2}^{n+} U_2^n - \tilde{\omega}_2^n = P_{E_2}^{n+} (U_2^n - \tilde{\omega}_2^n) = P_{E_2}^{n+} E_2^n, \]
since by our assumption \( \tilde{\omega}_2^n \in S_h \subset S_h^n \). Therefore \( \|E_2^{n+}\| \leq \|E_2^n\| \). For \( \|\nabla E_1^{n+}\| \) we have, noticing again that \( W_1(t) \in S_h \subset S_h^n \),
\[ \|\nabla E_1^{n+}\| = \|\nabla (P_{E}^{n+} U_1^n - W_1^n)\| \leq \|\nabla P_{E}^{n+} (U_1^n - W_1^n)\| + \|\nabla (W_1^n - W_1^n)\| \leq \|\nabla (U_1^n - W_1^n)\| + \|\nabla P_{E} (\int_{t^{n-1}}^{t^n} (I - T_{Lo}^{n-1,q}) u_t)\|. \]
But then as in Lemma 3.4,
\[ \|\nabla P_{E} (\int_{t^{n-1}}^{t^n} (I - T_{Lo}^{n-1,q}) u_t)\| \leq \|(\int_{t^{n-1}}^{t^n} (I - T_{Lo}^{n-1,q}) \nabla u_t)\| \leq k_{n-1}^{1/2} c k_{n-1}^{q+1} \|\nabla u^{(q+2)}\|_{L^2(I_{n-1};L^2)}, \]
which completes the proof. \( \Box \)

Therefore since no jump terms are present in this lemma, by applying the arguments in Section 3, we get

Theorem 4.1. Let \( u \) and \( U \) be the solutions of (1.1) and (1.3), respectively. Suppose \( S_h \subset S_h^n \) \( \forall n \), where \( S_h \) satisfies (4.1). Then
\[ \max_{t \in [0,T]} \left( \|u(t) - U_1(t)\| + \|u(t) - U_2(t)\| \right) \leq C \left\{ \max_m k_m^{q+1} C_t(u) + h^s C_x(u) \right\}. \]

Remark 4.1. The local mesh size version of the above result is obtained as before by replacing the assumption (4.3) by
\[ \|\nabla (v - P_E v)\| \leq c \|h^{s-1} v\|_{s}, \quad \|v - P_E v\| \leq c \|h^s v\|_{s}, \quad v \in H^s \cap H^1_0, \quad 2 \leq s \leq r. \]
Then the analog of Theorem 3.2 holds in our case without the jump terms present. Note however that the locality of the estimate in this case is “smeared out” since \( S_h \) does not include the moving refined parts of the mesh. On the other hand Theorem 4.1 establishes that in the present important case of mesh modification the optimal order of convergence is preserved.

5. Estimate for the Jump of the Riesz Projection

In applications, when it is needed to change the spatial mesh at some time level \( t^n \), the two meshes will be in general incompatible but will, more often than not, differ only in a region of small area. The following simple estimates show that the corresponding difference of the Riesz projections involves a factor that depends on the measure of the region of the incompatibility of the two meshes. To define the regions of incompatibility, we will use the following characterization. The set \( D^n_i \subset \Omega \) is called the incompatibility region for the meshes \( T_{h_i}^{n-1} \) and \( T_{h}^{n} \) if
\[ \text{for all } \varphi \in S_h^{n-1} \cup S_h^n \text{ with supp } \varphi = \Omega \backslash D^n_i \text{ it holds that } \varphi \in S_h^{n-1} \cap S_h^n, \]
and there is no other set that is contained in $D^n_k$ with this property. It is clear that the incompatibility region is simply the region where the meshes differ. Also, since we are using conforming elements, a transition layer is needed. This could consist of a layer, one-triangle across, surrounding $D^n_i$. We denote it by $D^n_\ell$ and we let $D^n = D^n_i \cup D^n_\ell$.

We will use the following lemma, which follows from SW Lemma 2.3.

**Lemma 5.1.** There exists a function $\eta \in S^{n-1}_h \cap S^n_h$, $\eta = J^n := (P^n_E - P^{n-1}_E)u(x,t)$ on $\Omega \setminus D^n$, and supp $\eta \subset \Omega \setminus D^n_\ell$, such that

$$\|J^n - \eta\|_{1,D^n_\ell} \leq c\|J^n\|_{1,D^n_\ell}.$$ 

We have the following

**Proposition 5.1.** If Lemma 5.1 holds, then

$$\|\nabla J^n\| \leq cm(D^n)^{1/2}\|J^n\|_{1,\infty}.$$ 

If in addition the space $S^{n-1}_h \cap S^n_h$ has the approximation property

$$\inf_{\varphi \in S^{n-1}_h \cap S^n_h} \|v - \varphi\|_1 \leq ch\|v\|_2,$$

then

$$\|J^n\| \leq cm(D^n)^{1/2}h\|J^n\|_{1,\infty}.$$ 

**Proof.** Let $\eta$ be as in Lemma 5.1. Since $\eta \in S^{n-1}_h \cap S^n_h$,

$$(\nabla J^n, \nabla \eta) = 0;$$

thus

$$\langle \nabla J^n, \nabla J^n \rangle = (\nabla J^n, \nabla J^n)_{\Omega \setminus D^n_\ell} + (\nabla J^n, \nabla J^n)_{D^n_\ell}
= (\nabla J^n, \nabla (J^n - \eta))_{\Omega \setminus D^n_\ell} + (\nabla J^n, \nabla \eta)_{\Omega \setminus D^n_\ell} + (\nabla J^n, \nabla J^n)_{D^n_\ell}
= (\nabla J^n, \nabla (J^n - \eta))_{D^n_\ell} + (\nabla J^n, \nabla \eta) + (\nabla J^n, \nabla J^n)_{D^n_\ell}
\leq \|\nabla J^n\|_{D^n_\ell} \|\nabla J^n - \eta\|_{D^n_\ell} + \|\nabla J^n\|_{D^n_\ell}^2
\leq c\|J^n\|_{1,D^n_\ell}^2 = cm(D^n)^{1/2}\|J^n\|_{1,\infty}.$$

For the $L^2$ estimate consider the function $\Psi \in H^2 \cap H^1_0$ that satisfies

$$(\nabla \Psi, \nabla v) = (J^n, v) \quad \forall v \in H^1_0.$$ 

Then for any $\Psi_h \in S^{n-1}_h \cap S^n_h$, the approximation property of $S^{n-1}_h \cap S^n_h$ implies

$$\|J^n\|_{2} = (\nabla \Psi_h, \nabla J^n)
= (\nabla (\Psi - \Psi_h), \nabla J^n)
\leq ch\|\nabla J^n\| \|\Psi\|_2 \leq ch\|\nabla J^n\| \|J^n\|,$$

and the proof follows. $\square$

**Remark 5.1.** One may get a similar result by working directly with, e.g., Clement’s interpolant, but we do not present this case here.

This result implies that, e.g., in $\mathbb{R}^d$ and if the diameter of $D^n$ is $O(h)$, then

$$\|\nabla (P^n_E - P^{n-1}_E)u(x,t)\| = O(h^{r+1+d/2}), \quad \|((P^n_E - P^{n-1}_E)u_t)(x,t)\| = O(h^{r+d/2}).$$ 

Note that the approximation assumption on $S^{n-1}_h \cap S^n_h$ is realistic. This is the case for example if $S^n_h$ is obtained from $S^{n-1}_h$ by refining the mesh in a part of the domain and derefining it in another part. This is what we do in most situations.
