RELIABLE A POSTERIORI ERROR CONTROL
FOR NONCONFORMING FINITE ELEMENT APPROXIMATION
OF STOKES FLOW

W. DÖRFLER AND M. AINSWORTH

Abstract. We derive computable a posteriori error estimates for the lowest
order nonconforming Crouzeix–Raviart element applied to the approximation
of incompressible Stokes flow. The estimator provides an explicit upper bound
that is free of any unknown constants, provided that a reasonable lower bound
for the inf-sup constant of the underlying problem is available. In addition, it
is shown that the estimator provides an equivalent lower bound on the error
up to a generic constant.

1. Introduction

1.1. Setting. The use of solenoidal (i.e., divergence-free) finite elements is attrac-
tive since it allows the decoupling of the velocity from the pressure in incompressible
flow calculations. It is well known that the only conforming solenoidal finite ele-
ments are based on high degree polynomials, and therefore, if one is to avoid high
degree finite elements, then one is obliged to use nonconforming elements. The
lowest order such element is the $\mathbb{P}_1-\mathbb{P}_0$ element (for the velocity and pressure com-
ponents, respectively), developed by Crouzeix and Raviart [9]. For an overview of
this and related methods, see [5, Ch. IV.3]. We point out that the analysis of this
element is confined to problems with pure Dirichlet boundary conditions due to its
failure to satisfy a discrete Korn’s inequality, although there is evidence that the
method is of practical use in spite of this apparent failing [23]. Furthermore, the
element is widely used in the numerical simulation of Stokes, Navier–Stokes and
non-Newtonian flow [20, 3, 13, 22, 24, 4].

Adaptive methods for nonconforming elements have been studied for some time
now, and a posteriori error estimates have been obtained that bound the true error
above and below. Early papers treated the case of the linear (and nonlinear) Poisson
problem [11, 13, 12, 19], and estimators for the Stokes problem have been obtained,
for example, in [26, 10, 7]. Maximum norm error estimators were derived in [11].
However, such estimates almost always contain generic (unknown) constants and
as such do not provide actual computable error bounds. Of course, it is possible to
attempt to evaluate the constants appearing in the error bounds [3] but this kind of approach generally leads to overly pessimistic estimates. An alternative approach is to attempt to estimate the error in functional outputs, as in [20].

It was observed in [2] that computable upper bounds can be derived for nonconforming elements where such unknown constants are absent. Moreover, the bounds are found to be not only accurate, but also easy and cheap to compute. We adopt a similar approach here to derive constant-free (for the upper bound) a posteriori error estimates for the Crouzeix–Raviart finite element approximation of Stokes flow provided that a lower bound for the inf-sup constant for the continuous problem is available.

The argument is presented in full detail for the case of homogeneous Dirichlet boundary conditions in two space dimensions. We also outline the modifications needed to generalize to nonhomogeneous data in planar domains and to the extensions to the three dimensional setting.

**Notation.** Throughout, we use standard notation for the Lebesgue \(L^p(G)^k\) and Sobolev \(H^m(G)^k\) spaces on some open domain \(G \subset \mathbb{R}^d\) for \(d, k \in \mathbb{N}\) and \(p \in [1, \infty]\). The norm on \(L^2(G)^k\) is denoted by \(| \cdot |_G\). For vector valued functions \(v = [v_i]_{i=1,d} : G \to \mathbb{R}^d\) we let \(\nabla v \equiv \text{grad}(v) := [\partial_j v_i]_{i,j=1,d'}\). \(\nabla \cdot v \equiv \text{div}(v) := \sum_{i=1}^d \partial_i v_i.\) In particular, for the two dimensional case, \(d = 2,\) we define \(\nabla^k := [\partial_2, -\partial_1]\) so that \(\nabla^k s = [\partial_2 s, -\partial_1 s]\) for scalar functions \(s : G \to \mathbb{R}\) and \(\nabla^k \cdot v \equiv \text{curl}_2(v) = \partial_2 v_1 - \partial_1 v_2.\) Likewise, for matrix valued functions \(A : G \to \mathbb{R}^{d,d}\) we let \(\nabla \cdot A\) be the vector field \(\sum_{j=1}^d \partial_j A_{ij}\) for \(i,j = 1,d'.\)

### 1.2. The Stokes problem

Let \(\Omega \subset \mathbb{R}^d, d \in \{2, 3\},\) be an open polygonal or polyhedral domain. For a given source \(f \in L^2(\Omega)^d,\) we seek a velocity field \(u : \Omega \to \mathbb{R}^d\) and a pressure \(p : \Omega \to \mathbb{R}\) satisfying the **Stokes equations**,\n
\[
-\Delta u + \nabla p = f \quad \text{in } \Omega, \\
\nabla \cdot u = 0 \quad \text{in } \Omega, \\
u = 0 \quad \text{on } \partial \Omega,
\]

subject to the side constraint \(\int_{\Omega} p = 0.\) Initially, we confine our attention to homogeneous boundary conditions but this assumption is relaxed in Section 4.

The **weak form** of the Stokes problem consists of seeking \(u \in V\) and \(p \in M\) satisfying

\[
\int_{\Omega} \{\nabla u : \nabla v - p \nabla \cdot v + \nabla \cdot u q\} = \int_{\Omega} f \cdot v \quad \forall v \in V, \forall q \in M,
\]

where

\[
V := H_0^1(\Omega)^d, \quad M := L^2_0(\Omega) := \left\{ q \in L^2(\Omega) : \int_{\Omega} q = 0 \right\}.
\]

If the **inf-sup condition**

\[
\inf_{q \in M} \sup_{v \in V} \frac{\int_{\Omega} \nabla \cdot v q}{||v|| ||g||} \geq c_0 > 0
\]

holds for some positive constant \(c_0\) depending on the domain \(\Omega\) and the norm \(|| \cdot || \equiv || \cdot ||_\Omega,\) then it may be shown (see [5] Ch. II.1 or [16] Ch. IV) that there
exists a unique solution of problem (1.2) which depends continuously on the data
\begin{equation}
|\nabla u| + c_0 |p| \leq C(\Omega, d)|f|.
\end{equation}

The mapping
\[ [u, v] \mapsto \int_{\Omega} \nabla u : \nabla v \]
defines a positive definite bilinear form on the closed subspace \( X \subset V \) defined by
\begin{equation}
X := \{ v \in H_0^1(\Omega)^d : \nabla \cdot v = 0 \}.
\end{equation}

As a matter of fact, this property may be exploited to reformulate the problem whereby we seek \( u \in X \) such that
\begin{equation}
\int_{\Omega} \nabla u : \nabla v = \int_{\Omega} f \cdot v \quad \forall v \in X.
\end{equation}

One advantage of reformulating the problem over the space \( X \) is that the pressure \( p \) does not appear explicitly and the problem for the velocity field is positive definite; although on the other hand, it is more difficult to discretise the subspace \( X \).

2. The nonconforming Crouzeix–Raviart element

2.1. Triangulation. Let \( K \) be a triangulation of the domain \( \Omega \subset \mathbb{R}^2 \). We assume that \( \overline{\Omega} = \bigcup_{K \in \mathcal{K}} K \) and that the nonempty intersection of distinct elements is either a single common edge or vertex of both elements. In addition, the triangles are supposed to be shape regular in the sense that the usual minimal angle condition holds uniformly over all sequences of triangulations. Observe that the triangulation need not necessarily be quasi-uniform, although the assumptions do mean that the triangulation will be locally quasi-uniform.

Let \( \overline{\mathcal{N}} \) be a set indexing the element vertices, the subset \( \mathcal{N} \) indexes vertices on the interior of the domain, while \( \mathcal{N}^\partial \) indexes vertices on the domain boundary. The centroid and area of an element \( K \in \mathcal{K} \) are denoted by \( x_K \) and \( |K| \), respectively. The piecewise constant function defined by \( h(x) := h_K \) for \( x \in K \), where \( h_K := \text{diam}(K) \), is used to define the mesh-size \( h \) of \( \mathcal{K} \). The vector \( n_K \) denotes the unit exterior normal on the boundary \( \partial K \) and \( t_K := n_K \perp \) denotes the unit tangent vector, obtained by a \( 90^\circ \) rotation of \( n_K \) in an anti-clockwise sense. We denote the set of all element edges by \( \mathcal{E} \), the set of interior edges by \( \mathcal{E} \), and the set of boundary edges by \( \mathcal{E}^\partial \). The midpoint and diameter of an edge \( \gamma \) are denoted by \( x_\gamma \) and \( h_\gamma \), respectively. Each edge \( \gamma \in \mathcal{E} \) is oriented by assigning a unit normal vector \( n_\gamma \), along with a corresponding unit tangent vector \( t_\gamma := n_\gamma \perp \). In the case of an exterior edge \( \gamma \in \mathcal{E}^\partial \) the vector \( n_\gamma \) is always taken to be the exterior normal on \( \partial \Omega \). Observe that these definitions mean that \( n_{K,\gamma} = \pm n_\gamma \) and \( t_{K,\gamma} = \pm t_\gamma \), and that the positive sign is always taken in the case of a boundary edge \( \gamma \subset \partial \Omega \).

It is useful to introduce broken spaces relative to a triangulation \( \mathcal{K} \). For example, the space \( H^1(\mathcal{K}) := \bigotimes_{K \in \mathcal{K}} H^1(K) \) consists of functions whose restriction to individual elements are locally \( H^1 \)-smooth, but which are in general discontinuous across element interfaces. Likewise, \( P^l(\mathcal{K}) \) denotes the space of piecewise polynomials of degree at most \( l \in \mathbb{N} \) with respect to the triangulation \( \mathcal{K} \). The subspace \( P^l(\mathcal{K}) \cap H^1(\Omega) \) consisting of continuous piecewise polynomials is denoted by \( P^l_c(\mathcal{K}) \).
Although functions in broken spaces are not differentiable at element boundaries, it is possible to define an elementwise gradient $\nabla_h w$ as follows:

$$\nabla_h w(x) := \nabla w(x), \quad x \in \text{int}(K), \quad \forall K \in \mathcal{K}.$$ 

On an interior edge $\gamma = \partial K \cap \partial K'$, the jump in the trace of $w \in H^1(K)$ across the edge is denoted by $[w]_\gamma := w_{K;\gamma} - w_{K';\gamma}$, where the elements are ordered so that the edge normal $n_\gamma$ points from $K'$ into $K$. Equally well, for a sufficiently smooth function $w$, $[\partial_w]_\gamma$ and $[\partial_n w]_\gamma$ denote jumps in traces of derivatives of $w$ across an interior edge, where $\partial_t := t \cdot \nabla$ and $\partial_n := n \cdot \nabla$ denote the normal and tangential derivatives.

2.2. The finite element space. The finite element discretisation of problem (1.2) is defined in terms of a pair of subspaces $V_h \subset V$ and $M_h \subset M$, consisting of piecewise polynomials relative to the triangulation $\mathcal{K}$ of the domain $\Omega$. In order for the discrete problem

$$\int_{\Omega} \{ \nabla_h u_h : \nabla_h v_h - p_h \nabla_h \cdot v_h + \nabla_h \cdot u_h q_h \} = \int_{\Omega} f \cdot v_h$$

$$\forall v_h \in V_h \forall q_h \in M_h$$

to be uniquely solvable, it is necessary for the pair $V_h, M_h$ to be properly balanced so that a discrete version of the inf-sup condition (1.3) is satisfied [5, p. 78]. Not all combinations give rise to a stable approximation. For instance, the lowest order combination $V_h \subset \mathbb{P}^1(K)^2$ and $M_h \subset \mathbb{P}^0(K)$ does not satisfy an inf-sup condition [5, p. 208].

Given a stable combination, the direct approach leads to a saddle point problem coupling the unknowns in the discrete velocity and pressure. Alternatively, by analogy with the approach involving the divergence-free subspace $X$ described in Section 1, one can obtain a symmetric positive definite system involving only the discrete velocity, through the introduction of the subspace $X_h \subset V_h$ consisting of discretely divergence-free functions. At first sight, such an approach has much to commend it. Unfortunately, it has been found [15] that the only nontrivial divergence-free conforming polynomials are of high order. Nevertheless, if one is prepared to relax the requirement for a conforming approximation of the velocity field and instead use a nonconforming scheme (details later), then it is even possible to use the lowest order approximation whereby $V_h \subset \mathbb{P}^1(K)^2$ and $M_h \subset \mathbb{P}^0(K)$. The extra freedom in the velocity means that this combination is stable in the sense that a discrete inf-sup condition is now satisfied, despite the fact that this fails to hold for the corresponding conforming combination. More importantly, it is possible to construct the subspace $X_h \subset V_h$ consisting of piecewise divergence-free functions explicitly.

Let $\theta_\gamma \in \mathbb{P}^1(K)$ be the first order scalar, nonconforming function uniquely defined by the conditions $\theta_\gamma(x_\gamma) = \delta_{\gamma \gamma'}$ for $\gamma, \gamma' \in \overline{\mathcal{E}}$. These functions are nonconforming in the sense that they fail to belong to the space $H^1(\Omega)$ since their traces are discontinuous across element interfaces. Nevertheless, such functions are continuous at edge midpoints and therefore satisfy a weakened conformity condition whereby the average values of the traces are continuous at element interfaces: $\int_{\gamma} v_{h;K} = \int_{\gamma} v_{h;K'}$ on $\gamma = K \cap K'$. The finite element spaces for the approximation of the
Stokes problem are then defined by

\[ V_h := \text{span}\{\tau_{\gamma}, \nu_{\gamma} : \gamma \in E\}, \quad M_h := \left\{ q \in H^1(K) : \int_{\Omega} q = 0 \right\}, \]

where \( \tau_{\gamma} := \theta_{\gamma} t_{\gamma} \) and \( \nu_{\gamma} := \theta_{\gamma} n_{\gamma} \). Evidently, the space \( V_h \) is nonconforming in the sense described above. The stability and convergence of this method are studied in the original paper of Crouzeix and Raviart [9].

Let \( X_h \) denote the subspace consisting of piecewise divergence-free functions,

\[ X_h := \text{span}\{v_h \in V_h : \nabla_h \cdot v_h = 0\}. \]

Owing to the lack of conformity, \( X_h \) is not a subspace of \( X \) given by (1.5). A basis for \( X_h \) can be defined explicitly as follows. For \( n \in \mathbb{N} \), let

\[ \rho_n := \sum_{\gamma \in E : x_n \in \gamma} \sigma_{n,\gamma} \nu_{\gamma}, \]

where \( \sigma_{n,\gamma} \in \{\pm1\} \) is chosen so that the vectors \( \sigma_{n,\gamma} n_{\gamma} \) defined on element edges trace a path around the node \( x_n \) in an anti-clockwise sense. The subspace \( X_h \subset V_h \) is then given by

\[ X_h = \text{span}\{\tau_{\gamma}, \rho_n : \gamma \in E, n \in \mathbb{N}\}. \]

In order to see this, first note that every \( v_h \in X_h \) satisfies \( 0 = \oint_{\partial K} v_h \cdot n_K = \int_K \nabla \cdot v_h \), by (2.3), and hence, since \( v_h \) is linear, it follows that \( \nabla \cdot v_h = 0 \) on \( K \).

As intimated earlier, the availability of an explicit representation for the subspace \( X_h \) means that it is possible to decouple the computation of the discrete velocity from the pressure field. The discrete velocity field \( u_h \in X_h \) is uniquely determined by the condition

\[ \int_{\Omega} \nabla_h u_h : \nabla_h v_h = \int_{\Omega} f \cdot v_h \quad \forall v_h \in X_h. \]

Once the discrete velocity is in hand, the corresponding pressure \( p_h \) can be computed, without having to solve a linear system, using a marching procedure over the triangulation as described in [17].

2.3. A projection operator. Let \( v \in V \) be given. Then the conditions

\[ \Pi_h v(x_\gamma) := \int_{x_\gamma} v \quad \forall \gamma \in E \]

define a unique function \( \Pi_h v \in V_h \). This rule defines a nonconforming projection operator \( \Pi_h : V \to V_h \). Moreover, the operator has the property \( \Pi_h : X \to X_h \).

To see this, first observe that the above conditions imply that \( \int_{x_\gamma} \Pi_h v \cdot n_K = \int_{x_\gamma} v \cdot n_K \) for all \( \gamma \in E \). Therefore, if \( v \in X \), then

\[ \int_{\partial K} \Pi_h v \cdot n_K = \int_{\partial K} v \cdot n_K = \int_K \nabla \cdot v = 0, \]

and hence \( \Pi_h v \in X_h \). Finally, the projection \( \Pi_h \) satisfies the following local interpolation estimate (see, e.g., [2]):

\[ \|v - \Pi_h v\|_K + h_K \|\nabla(v - \Pi_h v)\|_K \leq C h_K \|\nabla v\|_K \quad \forall K \in \mathcal{K} \quad \forall v \in V. \]
2.4. Enhanced approximation space. For later purposes we will embed \( V_h \times M_h \) into a pair of enhanced (higher order) conforming spaces \( V_h^* \subset V \) and \( M_h^* \subset M \). Roughly speaking, the enhanced velocity space \( V_h^* \) consists of continuous piecewise quadratic functions augmented by so-called cubic “bubble” functions associated with the element interiors, while the enhanced pressure space \( M_h^* \) consists of continuous piecewise linear functions. The precise details are as follows.

Given an edge \( \gamma \in \mathcal{E} \), let \( \theta^*_\gamma \) denote the conforming piecewise quadratic function defined uniquely by the conditions \( \int_{\gamma} \theta^*_\gamma = \delta_{\gamma \gamma} \) and \( \theta^*_\gamma(x_n) = 0 \) for all \( n \in N \).

Analogously to Section 2.2 we define

\[
\tau^*_\gamma := \theta^*_\gamma \mathbf{t}_\gamma, \quad \nu^*_\gamma := \theta^*_\gamma \mathbf{n}_\gamma, \quad \rho^*_n := \sum_{\gamma \in \mathcal{E} : x_n \in \gamma} \frac{\sigma_{nm}}{h_\gamma} \nu^*_\gamma.
\]

For each node \( n \in N \), let \( \phi^*_n \) be the conforming piecewise quadratic function uniquely defined by the conditions \( \phi^*_n(x_m) := \delta_{nm} \) and \( \int_{\gamma} \phi^*_n = 0 \) for all \( \gamma \in \mathcal{E} \).

Finally, let \( \beta^*_K \) be the piecewise cubic function supported on element \( K \), whose value at the centroid \( x_K \) is unity.

The enhanced spaces are defined by

\[
V_h^* := \text{span}\left\{ \tau^*_\gamma, \nu^*_\gamma, \phi^*_n \mathbf{e}_m, \beta^*_K \mathbf{e}_m : \gamma \in \mathcal{E}, n \in N, m \in \{1, 2\}, K \in \mathcal{K}\right\},
\]

\[
M_h^* := \left\{ q_h \in \mathbb{P}_2(K) : \int_{\Omega} q_h = 0 \right\},
\]

where \( \mathbf{e}_1 \) and \( \mathbf{e}_2 \) denote the unit basis vectors for the Euclidean space \( \mathbb{R}^2 \). As before, the associated subspace \( X_h^* \subset V_h^* \), defined by

\[
X_h^* := \left\{ v_h \in V_h^* : \int_{\Omega} \nabla \cdot v_h q_h = 0 \quad \forall q_h \in M_h^* \right\},
\]

has an important role to play. The resulting finite element space \( X_h^* \) may be regarded as an enriched Taylor–Hood space [5, Ch. 6.3].

3. A posteriori error estimates for homogeneous boundary data

For simplicity, we begin by considering the case of homogeneous boundary conditions and defer the treatment of the general case until later.

3.1. Error representation. Let \( e := u - u_h \in X + X_h \) and \( e_p := p - p_h \in L_0^2(\Omega) \) denote the error in the velocity and the pressure, respectively. Thanks to (1.2) and (2.1), these quantities satisfy

\[
\int_{\Omega} \{ \nabla_h e : \nabla v - e_p \nabla \cdot v \} = \int_{\Omega} \{ f \cdot v - \nabla_h u_h : \nabla \cdot v + p_h \nabla v \} \quad \forall v \in V.
\]

Lemma 1. Let \( \Pi_h : V \to V_h \) be the nonconforming projection operator defined in Section 2.3. Then,

\[
\int_{\Omega} \{ \nabla_h e : \nabla v - e_p \nabla \cdot v \} = \int_{\Omega} f \cdot (v - \Pi_h v) \quad \forall v \in V.
\]
Proof. With the aid of (3.1) and (2.1),
\[
\int_{\Omega} \{ \nabla h e : \nabla v - e_p \nabla \cdot v \} = \int_{\Omega} \{ f : v - \nabla u_h : \nabla v + p_h \nabla \cdot v \}
\]
\[
= \int_{\Omega} \{ f : (v - \Pi_h v) - \nabla u_h : \nabla (v - \Pi_h v) + p_h \nabla \cdot (v - \Pi_h v) \}
\]
\[
= \int_{\Omega} f : (v - \Pi_h v) - \sum_{K \in \mathcal{K}} \oint_{\partial K} (n \cdot \nabla u_h - p_h n) \cdot (v - \Pi_h v) \quad \forall v \in V,
\]
and then observe that the second term vanishes by definition of $\Pi_h$ since both $n \cdot \nabla u_h$ and $p_h n$ are constant on each edge $\gamma \subset \partial K$. \qed

3.2. Decomposition of the error. Following an idea of [12], we decompose the gradient of the error in the velocity in the form
\[
(3.2) \quad \nabla h e = \nabla e_0 + a,
\]
where $e_0 \in X$ is uniquely defined by
\[
(3.3) \quad \int_{\Omega} \nabla e_0 : \nabla v = \int_{\Omega} \nabla h e : \nabla v \quad \forall v \in X.
\]
The remainder $a \in L^2(\Omega)^{2,2}$ satisfies
\[
(3.4) \quad \int_{\Omega} a : \nabla v = 0 \quad \forall v \in X,
\]
and as a consequence (3.2) defines an orthogonal splitting of the error
\[
(3.5) \quad || \nabla h e ||^2 = || \nabla e_0 ||^2 + || a ||^2.
\]
Moreover, $a$ belongs to the closed subspace $Y$ of $L^2(\Omega)^{2,2}$ defined by
\[
Y := \{ w \in L^2(\Omega)^{2,2} : \int_{\Omega} w : \nabla v = 0 \quad \forall v \in X \}.
\]
Members of the subspace $Y$ share the following useful property.

Lemma 2. For each $w \in Y$ there exists a function $\omega \in L^2_0(\Omega)$ such that
\[
(3.6) \quad \int_{\Omega} w : \nabla v = \int_{\Omega} \omega \nabla \cdot v \quad \forall v \in V,
\]
i.e., $\nabla \cdot w = \nabla \omega$, and which satisfies the estimate
\[
(3.7) \quad || \omega || \leq \frac{1}{c_0} || w ||,
\]
where $c_0$ is the constant appearing in the inf-sup condition (1.3).

Proof. Integration by parts reveals that every $w \in Y \cap H^1(\Omega)^{2,2}$ satisfies
\[
- \int_{\Omega} (\nabla \cdot w) \cdot v = 0 \quad \forall v \in X.
\]
Hence, by [16, Ch. III.1], there exists $\omega \in H^1(\Omega) \cap L^2_0(\Omega)$ such that $\nabla \cdot w = \nabla \omega$. Equation (3.6) then follows by integration by parts. The validity of the inf-sup condition means that we may pick $v \in H^1_0(\Omega)^2$ such that $\nabla \cdot v = \omega$ and
\[
|| \omega ||^2 = \int_{\Omega} \omega \nabla \cdot v = \int_{\Omega} w : \nabla v \leq || w || || \nabla v || \leq \frac{1}{c_0} || w || || \omega ||,
\]
which completes the proof of the assertion. \qed
3.3. Upper a posteriori error bound. We are now in a position to describe the a posteriori error estimator and to prove that it gives computable upper bounds for the error. Let \( \mathbf{f}_K \) denote a constant approximation of \( \mathbf{f} \) on \( K \) (such as the mean value of \( \mathbf{f} \) over \( K \)). The estimator \( \eta_c \) for the conforming part \( e_0 \) of the error is defined by

\[
\eta_c := \left( \sum_{K \in \mathcal{K}} \eta_{2;K}^2 \right)^{1/2} \quad \text{with} \quad \eta_{2;K}^2 := \frac{1}{12} |K| \left\| \mathbf{f}_K \right\|^2 \sum_{\gamma \in \mathcal{E} : \gamma \subset \partial K} \left| \mathbf{x}_\gamma - \mathbf{x}_K \right|^2,
\]

where, it will be recalled, \( \mathbf{x}_K \) and \( \mathbf{x}_\gamma \) denote the centroid of the element and an edge \( \gamma \), respectively. The estimator \( \eta_{nc} \) for the remainder \( \mathbf{a} \) is defined by

\[
\eta_{nc} := \left\| \nabla_h (\mathbf{u}^* - \mathbf{u}_h) \right\| + \frac{1}{\varepsilon_0} \left\| \nabla \cdot \mathbf{u}^* \right\|,
\]

where \( \mathbf{u}^* \) is any function in \( H^1_0(\Omega)^2 \) and \( \varepsilon_0 \) is the lower bound in the inf-sup condition (1.3). The estimator for the total error \( e \) is obtained by summing the estimators

\[
\eta := \eta_c + \eta_{nc}.
\]

The presence of the constant \( \varepsilon_0 \) from the inf-sup condition in the expression for \( \eta_{nc} \) could be removed if one were prepared to construct a divergence-free post-processed approximation \( \mathbf{u}^* \). However, this is hardly a viable or practical proposition, and the presence of \( \varepsilon_0 \) is essentially unavoidable. Fortunately, bounds for \( \varepsilon_0 \) are available and can be obtained from [8, 25].

In order to describe the upper bound property of the estimator, it is convenient to introduce the data oscillation on \( K \) defined by

\[
\text{osc}(f)_K^2 = \sum_{K \in \mathcal{K}} \text{osc}(f)^2 := \sum_{K \in \mathcal{K}} |K| \left\| f - \mathbf{f}_K \right\|_K^2.
\]

**Theorem 1** (Upper a posteriori bound). Let \( \eta \) denote the estimator defined in (3.8)–(3.10). Then, for any choice \( \mathbf{u}^* \in H^1_0(\Omega)^2 \),

\[
\left\| \nabla_h e \right\| \leq \eta + C \text{osc}(f)_K,
\]

where \( C \) is a positive constant that depends only on the shape regularity of the mesh.

**Proof.** Thanks to the orthogonal splitting (3.5) of the error (3.2), it suffices to estimate the two contributions separately.

(i) Upper bound for \( \| \nabla e_0 \| \). By the definition of \( e_0 \), (3.3) and Lemma 1, we observe that for all \( v \in \mathbf{X} \),

\[
\int_{\Omega} \nabla e_0 : \nabla v = \int_{\Omega} \nabla_h e : \nabla v = \int_{\Omega} \mathbf{f} \cdot (v - \Pi_h v) = \sum_{K \in \mathcal{K}} \int_{\Omega} \mathbf{f} \cdot (v - \Pi_h v)
\]

\[
= \sum_{K \in \mathcal{K}} \left\{ \int_{K} \mathbf{f}_K \cdot (v - \Pi_h v) + \int_{K} (\mathbf{f} - \mathbf{f}_K) \cdot (v - \Pi_h v) \right\}
\]

\[
= \sum_{K \in \mathcal{K}} \left\{ \int_{K} \sigma_K : \nabla v + \int_{K} (\mathbf{f} - \mathbf{f}_K) \cdot (v - \Pi_h v) \right\}.
\]
where $\sigma_K$ is given by

$$\sigma_K(x) := -\frac{1}{2} \tilde{f}_K \otimes (x - x_K).$$

To verify the last step, first note that $\nabla \cdot \sigma = -1/2 \tilde{f}_K \nabla \cdot (x - x_K) = \tilde{f}_K$ on $K$ and that $\sigma_K n_K = -1/2 \tilde{f}_K n_K \cdot (x - x_K) = -|K|/(3h_s) \tilde{f}_K$ on $\gamma \subset \partial K$. Hence,

$$\int_{\partial K} \sigma_K n_K \cdot v = -\sum_{\gamma \subset \partial K} \tilde{f}_K \cdot \frac{1}{h_s} \int_{\gamma} v |\frac{1}{3}| K = -\int_K \tilde{f}_K \cdot \Pi_h v,$$

and the claim follows. Consequently, using the interpolation estimate (2.6), we obtain

$$|\nabla e_0| \leq \left( \sum_{K \in \mathcal{K}} |\sigma_K|^2 K \right)^{1/2} + C \left( \sum_{K \in \mathcal{K}} h_K^2 \|f - \tilde{f}_K\|^2 K \right)^{1/2} = \eta_c + C \text{osc}(f),$$

where the last equality follows from an explicit calculation of $|\sigma_K|^2 K$.

(ii) Upper bound for $|a|$. To estimate $a$ take any $w \in Y$ and choose an arbitrary element $u^* \in H_0^1(\Omega)^2$. Then, using (3.4) and Lemma 2, we obtain

$$\int_{\Omega} a : w = \int_{\Omega} \nabla_h(e - e_0) : w = \int_{\Omega} \nabla_h(-u_h) : w$$

$$= \int_{\Omega} \{ \nabla_h(u^* - u_h) : w - \nabla u^* : w \}$$

$$= \int_{\Omega} \{ \nabla_h(u^* - u_h) : w - \nabla \cdot u^* \omega \}.$$

The estimate now follows using the bound for $\omega$ from Lemma 2. \hfill \square

3.4. Choice of $u^*$. The quality of the estimator $\eta$ defined in (3.10) will depend on making a good choice for $u^*$. One possibility is to construct $u^*$ by post-processing the finite element approximation $u_h$. With this in mind, we begin by defining a mapping $P_h : X_h \rightarrow V_h^*$ onto the enhanced space $V_h^*$ defined in Section 2.4. First, the values of the (discontinuous) function $v_h$ are averaged at each node $x \in N$ as follows:

$$S(v_h)_n := \begin{cases} \sum_{K \in \mathcal{K} : x_n \in K} \omega_n; K v_h; K(x_n), & \text{for } x_n \in \Omega, \\ 0, & \text{for } x_n \in \partial \Omega, \end{cases}$$

where $\{\omega_n; K\}$ is any set of nonnegative weights satisfying $\sum_{K \in \mathcal{K} : x_n \in K} \omega_n; K = 1$. Secondly, each $v_h \in X_h$ may be uniquely written in the form $v_h = \sum_{\gamma \in E} v_{\gamma} \tau_{\gamma} + \sum_{n \in N} v_n \rho_n$, and a mapping $P_h : X_h \rightarrow V_h^*$ can be defined, therefore, by

$$P_h v_h := \sum_{\gamma \in E} v_{\gamma} \tau_{\gamma}^* + \sum_{n \in N} \{ v_n \rho_n^* + S(v_h)_n \phi_n^* \}.$$

By construction, it holds that $\int_{\gamma} P_h v_h \cdot n = \int_{\gamma} v_h \cdot n = 0$ for all $\gamma \in \mathcal{F}$, and it is easily verified that, for every $v_h \in X_h$,

$$\int_{\Omega} \nabla \cdot (P_h v_h) q_h \equiv 0 \quad \forall q_h \in M_h.$$
The post-processing scheme embodied in $P_h$ forms the basis for a family of post-processing schemes of the form

$$Q_h v_h := P_h v_h + \sum_{K \in \mathcal{K}} c_K \beta_K^*,$$

(3.14)

corresponding to various choices of the local vectors $c_K \in \mathbb{R}^2$ for $K \in \mathcal{K}$.

The simplest choice $c_K = 0$ gives an operator $Q^0_h$ which coincides with the basic post-processing scheme, i.e., $Q^0_h = P_h$. Alternatively, the freedom in the choice of coefficients of the bubble functions $\beta_K^*$ may be exploited to give a post-processed approximation $Q^{DDF}_h v_h$ belonging to the subspace $X^*_h$ of “discretely divergence-free” functions (2.9) by taking $c_K \in \mathbb{R}^2$ as suggested in [14]:

$$c^{DDF}_K = \frac{1}{\int_K \beta_K^*} \left( \int_{\partial K} (x - x_K) P_h v_h \cdot n - \int_K P_h v_h \right).$$

(3.15)

Note that this choice preserves the property $\int_{\gamma} Q_h u_h \cdot n = \int_{\gamma} P_h u_h \cdot n = \int_{\gamma} u_h \cdot n$ for all $\gamma \in \mathcal{T}$. The construction of the discretely divergence-free post-processing scheme $Q^{DDF}_h$ is motivated by the desire to implicitly control the influence of the term in (3.14) involving the inf-sup constant $c_0$. A more direct approach is to choose the constants $c_K$ to minimize this term. This can be achieved by choosing

$$\int_K \nabla \beta_K^* \otimes \nabla \beta_K^* c^{MIN}_K = - \int_K \nabla \cdot (P_h u_h) \nabla \beta_K^*,$$

and the associated “minimal-divergence” post-processing scheme is denoted by $Q^{MIN}_h$. Finally, in view of the fact that one obtains an upper bound regardless of the choice of $c_K$, we consider the post-processing scheme whereby the coefficients $c_K$ are chosen to minimize the upper bound:

$$\left( |\nabla \beta_K^*|_{L^2(K)}^2 Id + \frac{1}{c_0} \int_K \nabla \beta_K^* \otimes \nabla \beta_K^* \right) c^{OPT}_K$$

$$= - \int_K \nabla \cdot (P_h u_h + \frac{1}{c_0} \nabla \cdot (P_h u_h) Id) \nabla \beta_K^*,$$

and we denote the associated post-processing operator by $Q^{OPT}_h$.

3.5. Lower a posteriori error bound. Each of the post-processing schemes defined in the previous section gives $Q_h u_h \in H^1_0(\Omega)^2$ and, therefore, we may select $u^* = Q_h u_h$ in Theorem 1 to obtain upper bounds on the error. We shall show that each of these upper bounds also provides an efficient bound provided that the triangulation satisfies the additional condition whereby each element $K \in \mathcal{K}$ should have at most one edge on the exterior boundary $\partial \Omega$. Obviously, this assumption is not a serious practical limitation since it may be satisfied by performing a suitable refinement of any triangles that do not meet this requirement.

**Theorem 2** (Lower a posteriori bound). Suppose that each element $K \in \mathcal{K}$ has at most one edge on the exterior boundary. If the estimator $\eta_{loc}$ is defined by taking $u^* = Q_h u_h$, where $Q_h$ is any of the operators defined in Section 3.4 then

$$c \eta \leq |\nabla h e| + \text{osc}(f),$$

where $c$ is a positive constant that depends only on the shape regularity of the mesh.
Proof: The orthogonality of the splitting (3.2) means that it suffices to prove lower bounds for $|\nabla e_0|$ and $|a|$ individually.

(i) Lower bound for $|\nabla e_0|$. Let $\overline{f}$ denote the piecewise constant function whose value on $K$ is given by $\overline{f}_K$, and let $\sigma$ be defined as in the proof of Theorem 1. Then, for all $v \in X$, we have

$$\int_{\Omega} \nabla e_0 : \nabla v = \int_{\Omega} \sigma : \nabla v + \int_{\Omega} (f - \overline{f}) \cdot (v - \Pi_h v).$$

Let $K', K'' \in K$ be distinct elements sharing the common edge $\gamma = K' \cap K''$, and denote $\Omega_\gamma := K' \cup K''$. Let $s \in C_0^1(\Omega_\gamma)$ be compactly supported in $\Omega_\gamma$, and set $v := \nabla^\perp s$. Then, with the aid of (2.6), we obtain

$$\int_{\Omega} \sigma : \nabla v \leq |\nabla e_0|_{\Omega_\gamma} + C \text{osc}(f).$$

Moreover, from the definition of $\sigma$,

$$\int_{\Omega} \sigma : \nabla v = \sum_{K \in \{K', K''\}} \int_K \overline{f}_K \cdot (v - \Pi_h v) = \frac{|K|}{3h_\gamma} \int_\gamma \nabla^\perp s + \overline{f}_K \cdot t_K \int_\gamma s.$$

Observe that $t_K' + t_K'' = 0$ on $\gamma$, and so, for the sake of definiteness, we fix $t_K' = t_\gamma$. Furthermore,

$$\int_\gamma \nabla^\perp s = \int_\gamma (n_\gamma \cdot \nabla^\perp s) n_\gamma + \int_\gamma (t_\gamma \cdot \nabla^\perp s) t_\gamma = \int_\gamma \partial_n s \cdot t_\gamma,$$

where the first integral vanishes since $s$ vanishes at the endpoints of $\gamma$. Hence, setting $\lambda_0 \equiv \lambda_0(s) := \int_\gamma s$ and $\lambda_1 \equiv \lambda_1(s) := \int_\gamma \partial_n s$, we obtain

$$\frac{1}{h_\gamma} \int_{\Omega_\gamma} \sigma : \nabla v = -\frac{1}{3} \left( \frac{|K'|}{h_\gamma^2} \overline{f}_K' + \frac{|K''|}{h_\gamma^2} \overline{f}_K'' \right) \cdot t_\gamma \lambda_1 + \left( \overline{f}_K' - \overline{f}_K'' \right) \cdot t_\gamma \lambda_0.$$

Observe that the right hand side is invariant under a rescaling of the domain and so without loss of generality we may assume that $h_\gamma = 1$. The main idea is, through appropriate choices of $s$, to show that (3.17) gives rise to a pair of linearly independent equations in which the tangential components of $f_{K'}$ and $f_{K''}$ are regarded as unknowns. The choices of $s$ are constructed as follows. First, let $\varrho$ be the largest value such that $B_\varrho(x_\gamma) \subset \Omega_\gamma$. Let $s$ be a nonnegative function with support $\text{supp}(s) = B_{\varrho/2}(x_\gamma)$ and such that $s$ is radially symmetric about the midpoint $x_\gamma$, normalized so that $\text{max}(s) = 1$. Let $\delta$ satisfy $0 \leq \delta < \varrho/2$ and consider the functions $s_\delta := s(\cdot - \delta n_\gamma)$ obtained by shifting the support of $s$. The mapping $\delta \mapsto \lambda_0(s_\delta)$ is then a positive, symmetric and strictly decreasing function and $\delta \mapsto \lambda_1(s_\delta)$ is a nonconstant skew-symmetric function. Taking first $\delta = 0$ and then $\delta = \delta_0$ for some fixed value $\delta_0 \in (0, \varrho/2)$, we find that (3.17) gives a pair of linearly independent equations for the tangential components of $f_{K'}$ and $f_{K''}$. Consequently, there is a constant $C$, depending only on the shape of $\Omega_\gamma$, such that

$$\left| \overline{f}_{K'} \cdot t_\gamma \right| \leq \frac{C}{h_\gamma} \int_{\Omega_\gamma} \sigma : \nabla v.$$
where we have exploited the fact that \( |\nabla v|_{\Omega_h} \) is independent of \( \delta \). In fact, by a scaling argument, we deduce that there is a positive constant \( C \), again independent of \( \delta \), such that \( |\nabla v|_{\Omega_h} \leq C/h_\gamma \). Hence, with (3.16) and (3.18), we get
\[
|K'_{i/2} [\mathbf{f}_{K'} \cdot t_{\gamma}]_{K'} | \leq C h_\gamma^2 [f_{K'} \cdot t_{\gamma}] \leq C (\|\nabla e_0\|_{\Omega_h} + \text{osc}(f)).
\]

Since each element is assumed to have at most one edge on the exterior boundary, we can apply the same reasoning to another edge \( \gamma \neq \gamma' \) contained in \( \partial K' \). Further, since the set \( \{t_\gamma, t_{\gamma'}\} \) is linearly independent, we are able to estimate both components of \( f_{K'} \), and thereby arrive at the bound
\[
|K'_{i/2} [\mathbf{f}_{K'}]_{K'} | \leq C (\|\nabla e_0\|_{\Omega_h, \Omega_{\gamma'}} + \text{osc}(f)).
\]

Summation over all elements \( K \in K \) then yields
\[
c \eta \leq \|\nabla e_0\|_K + \text{osc}(f),
\]
since \( \eta_{K,K} \leq C [\mathbf{f}]_K \|x - x_K\|_K \leq C [\mathbf{f}]_K \|K\| \leq C |K|^{1/2} [\mathbf{f}]_K \).

(ii) Lower bound for \( |\mathbf{a}| \). The proof consists of two steps. In the first step we show that \( |\mathbf{a}| \) bounds a sum of jumps \( J_t \) (defined below) in the tangential derivatives of \( u_h \). Then, in the second step we show that these jumps bound the error estimator above.

(iii.1) \( |\mathbf{a}| \) bounds \( J_t \). Let \( K' \) and \( K'' \) be distinct elements sharing a common edge \( \gamma = K' \cap K'' \) and let \( s := \theta_\gamma z_\gamma \), where \( \theta_\gamma \) is defined as in Section 2.4 and \( z_\gamma \in \mathbb{R}^2 \) is a constant to be specified later. The function \( \nabla^\bot s \) is divergence-free and therefore \( \nabla^\bot s \in \mathcal{Y} \). Then, arguing as in the proof of Theorem (ii), we deduce that
\[
\int \mathbb{K} : \nabla^\bot s = - \int_{K' \cup K''} \nabla_h u_h : \nabla^\bot s = - \sum_{K \in \{K', K''\}} \oint_{\partial K} (t_K \cdot \nabla u_h) \cdot s \\
= - \int_\gamma [\partial_t u_h]_\gamma \cdot s.
\]

Choose \( z_\gamma := - [\partial_t u_h]_\gamma \). Then
\[
J_{t,\gamma}^2 := h_\gamma \int_\gamma [\partial_t u_h]_\gamma^2 = h_\gamma \int_\gamma \theta_\gamma^2 [\partial_t u_h]_\gamma^2 = - h_\gamma \int_{K' \cup K''} \mathbb{K} : \nabla^\bot (\theta_\gamma^2 [\partial_t u_h]_\gamma) \\
\leq ||\mathbb{a}||_{K' \cup K''} |\nabla^\bot \theta_\gamma^2| J_{t,\gamma},
\]
and by summing over \( \gamma \in \mathcal{E} \) we obtain
\[
J_t := \left( \sum_{\gamma \in \mathcal{E}} J_{t,\gamma}^2 \right)^{1/2} \leq C |\mathbb{a}|,
\]
where \( C \) is a positive constant independent of any mesh-size.

(ii.2) \( J_t \) bounds \( \eta_{bc} \). To this end take any \( K \in \mathcal{K} \) and let \( \mathcal{A}_K := \{\gamma' \in \mathcal{E} : \gamma' \subset \Omega_K\} \) be the set of all edges in \( \Omega_K := \bigcup \{K' \in \mathcal{K} : K \cap K' \neq \emptyset\} \). We now wish to bound
\[
q_K := \frac{||\nabla (u^* - u_h)||_K^2}{\sum_{\gamma \in \mathcal{A}_K} J_{t,\gamma}^2}
\]
from above. To finish, observe that \( \eta_{bc} \leq C ||\nabla_h (u^* - u_h)|| \). The form of \( u^* \) means that the denominator depends on at least as large a set of coefficients of \( u_h \) as the numerator. Since \( q_K \) is the quotient of two homogeneous quadratic forms,
it suffices to show that if the denominator vanishes, then so does the numerator. Thanks to a scaling argument, we may eliminate the mesh-size and consider a patch \( \Omega_K \) of elements of unit diameter. Suppose now that \( J_{t, \gamma} = 0 \) holds for all \( \gamma \in A_K \). If \( x_n \) is any vertex of \( K \) and \( \gamma = K \cap K' \), then by continuity in \( x_n \), we have \( |u_{h,K}(x_n) - u_{h,K'}(x_n)| \leq \int_\gamma |[\partial_t u_h]| = 0 \). Because all edges emanating from \( x_n \) are in \( A_K \), we conclude that \( u_h \) is continuous at \( x_n \). Since it is linear, it is thus continuous in \( \Omega_K \) and \( u^* = u_h \) on \( \partial K \). Thus \( u_{h,K} = P_h u_h|_K \) and therefore \( u^* = u_h + \gamma_h \beta_A \) on \( K \). If we show that \( d_K = 0 \) holds, we have that \( q_K \) is bounded by an \( h_K \)-independent constant, and we arrive at the bound \( \| \nabla_h (u^* - u_h) \| \leq CJ_h \) after summation over \( K \). By definition \( d_K \) vanishes in the case where \( u^* \) is defined using \( Q_h^{DF} \). In the case of \( Q_h^{OPT} \), the fact that both \( u^* \) and \( u_h \) are solenoidal implies that \( d_K \) again vanishes. Likewise, since \( Q_h^{MIN} \) is chosen to minimize the difference in the divergences of \( u^* \) and \( u_h \), we conclude that \( d_K \) vanishes in this case also, and a similar argument applies in the case of \( Q_h^{OPT} \).

□

We conclude this section by stating the a posteriori estimate for the combined error in velocity and pressure.

**Corollary 1** (A posteriori error estimate for the pressure). If the previous conditions and assumptions hold, then the error in the pressure is bounded above as follows:

\[
c_0 \| e_p \| \leq 2\eta + C \text{osc}(f).
\]

Therefore, the total error \( \| \nabla_h e \| + c_0 \| e_p \| \) is equivalent to our error estimate up to data oscillation terms.

**Proof.** First, applying Theorem 2 we at once derive

\[
c\eta \leq \| \nabla_h e \| + \text{osc}(f) \leq \| \nabla_h e \| + c_0 \| e_p \| + \text{osc}(f).
\]

It remains to give the upper a posteriori bound for \( \| e_p \| \). To this end, notice that thanks to the inf-sup condition (1.3),

\[
c_0 \| e_p \| \leq \sup_{v \in \mathbf{V} \setminus \{0\}} \left\{ \frac{1}{\| \nabla v \|} \int_{\Omega} e_p \nabla \cdot v \right\}.
\]

From the error representation formula in Lemma 1 we obtain

\[
\frac{1}{\| \nabla v \|} \int_{\Omega} e_p \nabla \cdot v = \frac{1}{\| \nabla v \|} \int_{\Omega} \{ \nabla_h e : \nabla v + f : (v - \Pi_h v) \}
\leq \| \nabla_h e \| + \left( \sum_{K \in K} \| \sigma_K \|_K^2 \right)^{1/2} + C \text{osc}(f) \leq 2\eta + C \text{osc}(f),
\]

where we used arguments as in the proof of Theorem 1. Hence

\[
\| \nabla_h e \| + c_0 \| e_p \| \leq 3\eta + C \text{osc}(f)
\]

as claimed. □
4. Extension to nonhomogeneous boundary data

Consider the case of nonhomogeneous boundary conditions in which problem (1.1) is modified by requiring \( u = u^0 \) on \( \partial \Omega \) for some \( u^0 \in H^1(\partial \Omega)^2 \) satisfying \( \int_{\partial \Omega} u^0 \cdot n = 0 \). The latter condition is necessary for the problem to be well-posed. Further details concerning existence theory in this situation may be found in [10, Ch. IV]. Here, we will restrict ourselves to outlining the modifications necessary to extend our previous results, Theorem 1 and Theorem 2, to cover this situation. The nonhomogeneous boundary conditions are applied to the discrete problem by requiring that

\[ \int_{\gamma} u_h = \int_{\gamma} u^0 \quad \forall \gamma \in \mathcal{E}^\partial. \]

Note that applying the boundary conditions in this fashion guarantees that \( \int_{\partial \Omega} u_h \cdot n = 0 \). The enhanced approximation \( Q_h u_h \) from Section 2 is modified to satisfy the condition \( Q_h u_h(x_n) := u^0(x_n) \) for all \( x_n \in \partial \Omega \). In particular, there holds \( \int_{\gamma} Q_h u_h \cdot n = \int_{\gamma} u_h \cdot n = \int_{\gamma} u^0 \cdot n \) for all \( \gamma \in \mathcal{E}^\partial \). For given data \( u^0 \in H^1(\partial \Omega)^2 \), the theoretical bounds will involve the quantity

\[ \text{osc}(\partial_t u^0)^2 = \sum_{\gamma \in \mathcal{E}^\partial} \text{osc}(\partial_t u^0)^2 := \sum_{\gamma \in \mathcal{E}^\partial} h_{\gamma} |\partial_t u^0 - (\overline{\partial_t u^0})|_{\gamma}^2, \]

where \( (\overline{\cdot})_\gamma \) denotes the mean value integral over \( \gamma \).

**Theorem 3** (A posteriori bounds in case of nonhomogeneous boundary conditions). Suppose that the estimator \( \eta_{sc} \) is obtained by choosing \( u^* := Q_h u_h \). Then, Theorem 1 is modified to

\[ |\nabla_h e| \leq \eta + C \left( \text{osc}(f) + \text{osc}(\partial_t u^0) \right), \]

while Theorem 2 is modified to

\[ c \eta \leq |\nabla_h e| + \text{osc}(f) + \text{osc}(\partial_t u^0). \]

The constants \( c, C \) depend only on the shape regularity of the mesh.

**Proof.** We outline the necessary modifications to the proofs given earlier in the case of homogeneous data. The splitting of the error remains as stated in [82], but the arguments in the proofs of Theorems 1 and 2 have to be modified when we come to bound \( |a| \). To extend our previous results to nonhomogeneous data, it is useful to introduce a function \( v^* \in H^1(\Omega)^2 \) with exact boundary values \( u^0 \). On an interior element \( K \in \mathcal{K} \), we simply take \( v^* := u^0 \). A more elaborate argument is needed for a triangle \( K \) with an exterior edge \( \gamma \). First, define \( \xi^\beta_K := 0 \) on \( \partial K \setminus \gamma \) and \( \xi^\partial_K := u^0 - u^* \) on \( \gamma \). By construction \( \int_{\partial K} \xi^\partial_K \cdot n = \int_{\gamma} (u^0 - u^*) \cdot n = 0 \). Hence, an elementwise Stokes problem on \( K \) with boundary data given by \( \xi^\partial_K \) has a solution that we denote by \( \xi_K \) and which satisfies the bound \( |\nabla \xi_K|_K \leq C \text{osc}_K(\partial_t u^0) \) (obtained using arguments similar to those of [2, Lemma 8]). On each such element \( K \) we define \( v^* := u^* + \xi_K \). In summary, the function \( v^* \in H^1(\Omega)^2 \) satisfies \( v^* = u^0 \) on \( \partial \Omega \).
(i) Upper bound for \(|a|\). These previous definitions mean that step (ii) in the proof of Theorem 1 must be modified as

\[
\int_\Omega a : w = \int_\Omega \nabla_h (e - e_0) : w = \int_\Omega \nabla_h (u - u_h) : w = \int_\Omega \{ \nabla_h (v^* - u_h) : w + \nabla (u - v^*) : w \}
\]

\[
= \int_\Omega \{ \nabla_h (v^* - u_h) : w - \nabla \cdot u^* \omega \} + \sum_{K \in K^H} \int_\Omega \nabla \xi_K : w,
\]

since \(\nabla \cdot \xi_K = 0\). It only remains to estimate the final term:

\[
\sum_{K \in K} \int_\Omega \nabla \xi_K : w \leq \left( \sum_{K \in K} \| \nabla \xi_K \|^2_K \right)^{1/2} \|w\| \leq C \text{osc}(\partial_t u^\theta) \|w\|.
\]

(ii) Lower bound for \(|a|\). We only have to reconsider part (ii.2) of the proof to Theorem 2. We will split \(u^* - u_h = (u^* - \tilde{u}^*) + (\tilde{u}^* - u_h)\), where \(\tilde{u}^*\) is as \(u^*\), but with \(\tilde{u}^*(x_n) := S(u_h)_n\), also for \(x_n \in \mathcal{N}_\partial\) in contrast to \(u^*(x_n) = u^\partial(x_n)\). The term \(\|\nabla (\tilde{u}^* - u_h)\|\) is treated as in part (ii) before, so that it remains to bound \(\|\nabla (u^* - \tilde{u}^*)\|\).

First consider an element \(K \in \mathcal{K}\) with a boundary edge \(\gamma\) and boundary vertices \(x_n, x_m\). The following argument is based on the observation

\[
\|\nabla (u^* - \tilde{u}^*)\|_K \leq C \max_{\ell \in \{n, m\}} \|(u_{h;K} - u^\partial)(x_\ell)\|.
\]

Using the discrete boundary conditions yields \((u_{h;K} - u^\partial)(x_n) = h_\gamma/2 \partial_t u_{h;K} + \int \nabla \cdot u^\partial - u^\partial(x_n),\) and with arguments as in the proof of Theorem 2(i.1) with \(s := \theta^*_\gamma z_\gamma\),

\[
\int_K a : \nabla^\perp s = \left( \int_\gamma \theta^*_\gamma \partial \gamma u^\partial - h_\gamma \partial_t u_{h;K} \right) \cdot z_\gamma
\]

\[
= -2(u_{h;K} - u^\partial)(x_n) + \int_\gamma \theta^*_\gamma \partial_t u^\partial + 2 \int_\gamma u^\partial - 2 u^\partial(x_n) \cdot z_\gamma
\]

or

\[
2(u_{h;K} - u^\partial)(x_n) \cdot z_\gamma
\]

\[
= - \int_K a : \nabla^\perp s + \left( \int_\gamma \theta^*_\gamma (\partial_t u^\partial - (\partial_t u^\partial)_\gamma) \right)
\]

\[
+ 2 \int_\gamma u^\partial - (u^\partial(x_n) + u^\partial(x_m)) \cdot z_\gamma.
\]

The last two terms can be written in the form \(\int_\gamma \chi_\gamma (\partial_t u^\partial - (\partial_t u^\partial)_\gamma)\) with \(|\chi_\gamma| = 1/2\) (see [2] Lemma 9) so we conclude, choosing \(z_\gamma = [1; 0]\) and \([0; 1]\), that

\[
|(u_{h;K} - u^\partial)(x_n)| \leq C \left( |a|_K + h_\gamma |\partial_t u^\partial - (\partial_t u^\partial)_\gamma| \gamma \right) \leq C (|a|_K + \text{osc}(\partial_t u^\partial)).
\]

The remainder of the argument then proceeds as in the case of homogeneous data. \[\square\]
5. Three dimensional case

To emphasize the similarities with the previous considerations, we adopt a notation analogous to the two dimensional case. We assume $\Omega$ is decomposed into a set $K$ of tetrahedra satisfying the usual assumptions. Further, let $\tilde{E}$ be the set of all faces of tetrahedra in $K$ and let $V$ be an index set for the edges. Faces and edges are assumed to be oriented in the following way: with each face $\gamma \in \tilde{E}$, a normal vector $n_\gamma$ is assigned (which coincides with the exterior normal if $\gamma \subset \partial \Omega$) and each edge has a fixed direction, e.g., pointing to the vertex with the larger index in the set of vertices $V := \{x_j\}_j$. For $\gamma \in E$, let $\theta_\gamma$ be the linear nonconforming basis function satisfying $\theta_\gamma(x_{\gamma'}) = \delta_{\gamma\gamma'}$, where $x_{\gamma'}$ is the centroid of $\gamma'$. On the face $\gamma$ we construct an orthonormal basis $\{t_{\gamma,1}, t_{\gamma,2}\}$ satisfying $(t_{\gamma,1} \times t_{\gamma,2}) \cdot n_\gamma = 1$. By analogy with the two dimensional case, we define basis functions $\tau_{\gamma,l} := \theta_\gamma t_{\gamma,l}$ and $\nu_\gamma := \theta_\gamma n_\gamma$. The spaces $V_h$ and $M_h$ are defined as in (2.2), and the degrees of freedom for $V_h$ are identified with the functionals $\bar{f}_\gamma \nu_h$.

The construction of the subspace $X_h$ involves choosing an appropriate subset $N_X$ of $N$ and defining $\rho_n$ as in (2.1) for $n \in N_X$. Signs are chosen such that the face normals $\rho_n(x_{\gamma'})$ trace a path around the edge $n$ in the anti-clockwise sense with respect to the chosen orientation of this edge. The definition of $\mathbf{H}$ remains as described in Section 2.3 and in particular, functions in $X$ will be automatically mapped into $X_h$.

We will now sketch the differences to the two dimensional case needed to extend the a posteriori error bounds in Theorems 1 and 2 under the assumption of homogeneous boundary data.

Modifications to the proof of Theorem 1. Definition 3.10(i) has to be replaced by

$$\eta^2_{1,K} := \frac{|K|}{36} |f_K|^2 \sum_{\gamma \in \tilde{E}, : \gamma \subset \partial K} |x_\gamma - x_K|^2$$

for the conforming error, since we will obtain $\sigma_K := -1/3 |f_K| \otimes (x - x_K)$ for $K \in K$ in the proof of Theorem 1(i), with the same technique as before (note that $(x - x_K) \cdot n_K = 3/4 |K|/|\gamma| \forall x \in \gamma \subset \partial K$). Part (ii) works exactly the same way.

A choice of $u^*$. Before proving the lower bound, we have to be more specific about the choice of $u^*$. One possibility is to choose $V_h^* = P_3(\mathcal{K})$ enriched by face bubbles in normal directions [21, p. 122]. For this let $\theta^*_\gamma$ be the cubic face bubble for $\gamma \in \tilde{E}$ with $\int_{\gamma} \theta^*_\gamma = 1$. For each vertex $x_j$ let $\phi_j$ its piecewise linear basis function and let $S(v_h)_{x_j}$ be the weighted mean for $v_h \in V_h$ as in (3.11). We then define $P_h : V_h \rightarrow V_h^*$ by $P_h v_h := \sum_{j \in \gamma} S(v_h)_{x_j} \phi_j + \sum_{\gamma \in \tilde{E}} T(v_h)_{\gamma} \phi^*_{\gamma} n_\gamma$, where $T(.),_{\gamma}$ is chosen such that $\int_{\gamma} P_h v_h \cdot n_\gamma = \int_{\gamma} v_h \cdot n_\gamma$. Thus we obtain that for $v_h \in X_h$, (3.13) holds for piecewise constant $q_h$ and, therefore, $M_h^* = M_h = P_0(\mathcal{K})$. Our choice here is $u^* := P_h u_h$.

Modifications to the proof of Theorem 21. Taking $v := \nabla \times r_l$, where $r_l := s t_{\gamma,l}$ for some $s \in C_0^0(\Omega_\gamma)$ and $l \in \{1,2\}$, we achieve $\nabla \cdot v = 0$. Now we obtain, for some $c_\gamma > 0$,

$$\int_{\Omega} \sigma : \nabla v = \sum_{K \in \{K',K''\}} \left\{-c_\gamma |f_K|^2 \int_{\gamma} \nabla s \times t_{\gamma,l} + |f_K| \cdot (n_\gamma \times t_{\gamma,l}) \int_{\gamma} s \right\}.$$
Using \( \{l,l'\} = \{1,2\} \) and cyclic permutation, we see that
\[
\int_\gamma \nabla s \times t_{\gamma,V} = \int_\gamma (\nabla s \times t_{\gamma,l}) \cdot t_{\gamma,l'} \sim \int_\gamma \partial_n s \ t_{\gamma,l'}
\]
and \( \int_K (\nabla \gamma \times t_{\gamma,l}) \sim \int_K \cdot t_{\gamma,l'}. \) Hence, we end up in the same situation as in \( (3.17) \)
and, with the same choice of \( s \) as before, one obtains an estimate for the tangential part of \( \int_K \) on \( \gamma \) and, using a second face of \( K \), an estimate for the whole vector.

*Modifications to the proof of Theorem 2(ii.1).* For \( l \in \{1,2\} \) let \( v_i := z_l t_{\gamma,l} \theta^*_\gamma \) for some \( z \in \mathbb{R}^3, i \in \{1,2,3\}, l' \) such that \( \{l,l'\} = \{1,2\} \). Define \( w(x) \) to be the matrix with \textit{ith row} \( \nabla \times v_i(x) \). Then \( \nabla \cdot w = 0 \) so that \( w \in Y \), and one obtains
\[
\int_\Omega a : w = -\int_\Omega \sum_{i=1}^3 \nabla_h u_{h,i} \cdot \nabla v_i = -\sum_{i=1}^3 [\nabla u_{h,i}]_\gamma \cdot (n_{\gamma} \times t_{\gamma,l'}) z_i h_{\theta^*_\gamma}
\]
Choosing \( z = [\partial_{\theta^*_\gamma} u_{h}]_\gamma \) yields the required bound.

*Modifications in the proof of Theorem 2(ii.2).* The essential steps are to show that \( P_h u_{h \mid K} \) depends on coefficients of \( u_h \) on \( \Omega_K \) and that vanishing jumps for \( \gamma \in \mathcal{A}_K \) imply \( u^* = u_h \) on \( K \). The first property is immediate. For the second we show that, as before, \( u_h \) is continuous on \( \Omega_K \) and thus equals \( u^* \) at all vertices. Since \( \nabla \cdot u_h = 0 \) we see that \( T(u_h)_\gamma = 0 \) for all \( \gamma \subset \partial K \) and, therefore, \( u^* = u_h \) on \( K \).

6. **Numerical examples**

We show numerical results for two examples. The first one has a polynomial velocity field of third order on \( \Omega := (0,1)^2 \) with nonhomogeneous data \( f \) and \( u^\circ \). Velocity, stream function, and pressure, respectively, are given by
\[
\begin{align*}
   u_e(x_1,x_2) &= [x_1(1-x_1)(1-2x_2), -x_2(1-x_2)(1-2x_1)], \\
   \Psi_e(x_1,x_2) &= x_1x_2(1-x_1)(1-x_2), \\
   p_e(x_1,x_2) &= 2(x_2-x_1).
\end{align*}
\]
The second example (see, e.g., [20]) has a singular solution \( (u_e \not\in H^2(\Omega)^2) \) on the L-shaped domain \( \Omega := (-1,1)^2 \setminus (0,1) \times (-1,0) \) with \( f = 0 \), explicitly given by
\[
\begin{align*}
   u_e(r,\phi) &= r^\alpha \left[ (\alpha+1) \sin(\phi) \psi(\phi) + \cos(\phi) \psi'(\phi), \\
   &\quad -(\alpha+1) \cos(\phi) \psi(\phi) + \sin(\phi) \psi'(\phi) \right], \\
   \Psi_e(r,\phi) &= r^{\alpha+1} \psi(\phi), \\
   p_e(r,\phi) &= \frac{1}{\alpha-1} r^{\alpha-1} ((\alpha+1)^2 \psi'(\phi) + \psi''(\phi))
\end{align*}
\]
in polar coordinates \( [r,\phi] \in (0,\infty) \times (0,3\pi/2) \), where
\[
\begin{align*}
   \psi(\phi) &= \frac{1}{\alpha+1} \sin((\alpha+1)\phi) \cos(\omega) - \cos((\alpha+1)\phi), \\
   &\quad + \frac{1}{\alpha-1} \sin((\alpha-1)\phi) \cos(\omega) + \cos((\alpha-1)\phi), \\
   \alpha &= \frac{856399}{1572864} \approx 0.54, \quad \omega = 3\pi/2.
\end{align*}
\]
Table 1. Results for Example 1 on the uniform grid with \( N = 3969 \) (left) and for Example 2 on the uniform grid with \( N = 5985 \) (right) for the different choices of \( Q_h \).

In the experiments we calculate the “exact” (using a quadrature formula for \( P^2 \)) and the estimated error in the energy norm \( \| \nabla \cdot \| \) (using a quadrature formula for \( P^3 \)) for the velocity on a sequence of uniformly and adaptively refined grids, respectively. For each marked triangle two newest node bisection steps [27] were performed. As a local error indicator for the adaptive algorithm we used (cf. Section [36])

\[
\eta_K^2 := \eta_{c,K}^2 + \| \nabla (u^* - u_h) \|^2_K + \frac{1}{c_0} \| \nabla \cdot u^* \|^2_K,
\]

and triangles are marked using the maximum strategy (mark \( K \) if \( \eta_K \geq \eta_{\text{max}}/2 \)). The global error estimate is, according to (3.10), given by

\[
\eta := \eta_c + \eta_{\text{sc}}.
\]

Values for the constant \( c_0 = 0.4 \) for \( \Omega = (0,1)^2 \) and \( c_0 = 0.3 \) for the L-shaped domain have been obtained from [24] pp. 253–254. All errors will be presented as relative errors. For convenience, the following abbreviations will be used: \( E := \| \nabla (u_e - u_h) \|/\| \nabla u_e \| \), \( \eta := \eta/\| \nabla u_e \| \), \( \eta^{(u)} := \| \nabla (u^* - u_h) \|/\| \nabla u_e \| \), \( \eta^{(d)} := \| \nabla \cdot u^* \|/\| \nabla u_e \| \).

Table 1 compares the bounds obtained using the four different types of post-processing scheme used to define \( u^* \) in the case of a uniform grid. Observe that the estimators involving \( Q_h^{OPT} \) and \( Q_h^{MIN} \) perform comparably and represent a significant improvement over the estimators based on \( Q_h^0 \) and \( Q_h^{DDF} \) in this example.

Figure 1 shows the convergence history for both examples on a sequence of uniformly and adaptively refined grids; Tables 2 and 3, the corresponding data. In the first example, which is \( H^2 \)-regular, the slope of the lines is about \(-1/2\), confirming the expected relations \( E \sim N^{-1/2} \) and \( \eta^{(u)} \sim N^{-1/2} \), respectively. However, the exact error is overestimated by a factor of about 3.5. In the second example the slope of the data in the uniform case is about \(-1/4\), which is consistent with the expected rate of \(-\alpha/2\). The adaptive algorithm improves upon this by that the error decreases with \( N^{-1/2} \) as in the \( H^2 \)-regular case. This confirms that the adaptive algorithm is quasi-optimal, although, once again, there is overestimation by a factor of about 3 in the uniform case and approximately 3.9 in the adaptive case.

The cost of using \( Q_h^{OPT} \) is about 10\% more than that for \( Q_h^0 \). Pressure errors are of the size of the velocity errors, and the overestimation of \( \eta \) with respect to \( \| \nabla (u_e - u_h) \| + c_0 \| p_e - p_h \| \) is about a factor of 3.
