APPROXIMATION OF NONLINEAR WAVE EQUATIONS WITH NONSTANDARD ANISOTROPIC GROWTH CONDITIONS

JONAS HAEHNLE AND ANDREAS PROHL

Abstract. Weak solutions for nonlinear wave equations involving the $p(x)$-Laplacian, for $p : \Omega \to (1, \infty)$ are constructed as appropriate limits of solutions of an implicit finite element discretization of the problem. A simple fixed-point scheme with appropriate stopping criteria is proposed to conclude convergence for all discretization, regularization, perturbation, and stopping parameters tending to zero. Computational experiments are included to motivate interesting dynamics, such as blowup, and asymptotic decay behavior.

1. Introduction

Let $T > 0$, and $\Omega \subset \mathbb{R}^d$, $d \geq 1$ be a bounded Lipschitz domain. Consider $p \in C(\overline{\Omega}; (1, \infty))$, such that

\begin{equation}
|p(x) - p(y)| \leq \frac{c}{\ln |x - y|} \quad \forall |x - y| < \frac{1}{2},
\end{equation}

for some $c > 0$. Suppose that $f : \Omega \times \mathbb{R} \to \mathbb{R}$ is continuous, with suitable growth conditions, and $F(x,u) = \int_0^u f(x,s) \, ds$. Given $(u_0, v_0) \in W_{0}^{1,p(x)}(\Omega) \times L^2(\Omega)$, we seek (global weak) solutions $u : (0, T) \times \Omega \to \mathbb{R}$, such that ($\alpha \geq 0$)

\begin{equation}
\begin{aligned}
& u_{tt} - \text{div}(|\nabla u|^{p(x)-2}\nabla u) - \alpha \Delta u + f(x, u) = 0 \quad \text{in } \Omega_T := (0, T) \times \Omega, \\
& u(0, \cdot) = u_0, \quad u_t(0, \cdot) = v_0 \quad \text{in } \Omega, \\
& u = 0 \quad \text{on } \partial \Omega_T := (0, T) \times \partial \Omega.
\end{aligned}
\end{equation}

This is a prototype problem with nonstandard $p(x)$-growth condition, and energy functional

\begin{equation}
E_p[u, v] = \int_{\Omega} \left[ \frac{1}{p(x)}|\nabla u|^{p(x)} + \frac{1}{2}|v|^2 + F(x, u) \right] \, dx \quad \text{for } p \in C(\overline{\Omega}; (1, \infty)),
\end{equation}

where the classical solutions to (1.2) satisfy

\begin{equation}
E_p[u(t, \cdot), u_t(t, \cdot)] + \alpha \int_{\Omega_T} |\nabla u_t|^2 \, dx \, dt = E_p[u_0, v_0] \quad \forall t \geq 0.
\end{equation}

One motivation comes from studying evolutionary problems with nonstandard anisotropic growth conditions, which may e.g. provide further insight into the behavior of solutions of semi-/quasilinear wave equations with critical (de-)focusing nonlinearities, such as finite time blow-up behavior \cite{22, 27, 14, 16, 7, 32, 17, 18}, decay behavior of global solutions \cite{26, 21, 8}, relevancy of weak and vs. strong...
damping in this context, and/or dependence of solutions on initial data of small, finite, or infinite energies. A possible physical motivation for (1.2) are models from viscoelasticity, where (1.2) for $2 \leq p \equiv \text{const}$ is the subject of several studies; see e.g. [24, 14].

Functionals with variable exponents (1.3) are currently the subject of intensive research, and analytical studies of variational problems with nonstandard $p(x)$-growth have led to interesting results, and are still rapidly developing; see e.g. [15, 28]. However, it is only recently that related parabolic equations with anisotropic nonstandard growth conditions have been studied, both analytically and numerically [29], where the latter work includes computational studies to motivate decay behavior, or blowup of solutions for supercritical nonlinearities. The goal of this work is to extend this program to the nonlinear wave equation (1.2).

In particular, we

1. construct a convergent finite element based scheme: A fully practical discretization is provided, which includes a fixed-point strategy to solve nonlinear algebraic problems at each iteration step, in combination with an appropriate stopping criterion. In particular, the fixed-point algorithm requires a regularization $\Delta_p^{\delta}(x)u := \text{div} \left( \| \nabla u \|^2 + \delta(x) \frac{2}{p^*(x) - 2} \nabla u \right)$, for $\delta \in L^\infty(\Omega, (0, 1])$ of $\Delta_p(x)u := \text{div} \left( \| u \|^p(x) - 2 \nabla u \right)$ in (1.2) to validate a contraction property for all $p \in C(\Omega, [2, \infty))$. Overall convergence of iterates to a weak solution of (1.2) in the sense of Definition 2.1 will be shown for all discretization, perturbation, regularization, and thresholding parameters tending to zero.

2. perturb the numerical scheme: Since a complicated $p : \Omega \to [2, \infty)$ crucially affects numerical integration, approximations $p_{\epsilon} \in C(\Omega, [2, \infty))$ might be useful; we verify that for $p_{\epsilon} \downarrow p$ simultaneously to other convergences in item (1), iterates of the numerical scheme (see Scheme A, and Algorithm A1 below) converge to weak solutions of (1.2).

3. computationally study the qualitative behavior of solutions: Scheme A and Algorithm A1 are convergent discretizations, in the sense that subsequences of solutions converge to weak solutions of (1.2). This theoretical background justifies computational studies to motivate interesting behaviors of weak solutions of (1.2), such as asymptotic decay properties for subcritical nonlinearities. Moreover, computational experiments are provided for situations which cannot be covered theoretically so far, such as $\alpha = 0$, and values $p_-$ := $\inf_{\Omega} p < 2$, large or infinite initial energies, and supercritical involved nonlinearities.

The remainder of this work is organized as follows. In Section 2 we recall useful properties of the Orlicz spaces $L^{p(x)}$ and $W^{m,p(x)}$, and define weak solutions of (1.2). In Section 3 we propose an implicit, regularized finite element discretization of (1.2) (Scheme A) and validate solvability, and obtain a discrete version of the energy identity (1.4) for iterates of Scheme A ($\alpha \geq 0$ and $p_- > 0$). Subsequence convergence of iterates to weak solutions in the sense of Definition 2.1 for (independently) vanishing discretization and regularization parameters is stated in Theorem 3.1 for $\alpha > 0$, and $p_- \geq 2$. This result is achieved for initial data of finite energy, and functions $f$ in (1.2) which satisfy the asymptotic growth condition (2.3), for $1 < \gamma < p_-$. 
Solving nonlinear problems in Scheme A requires an iterative procedure; in Section 4, we discuss how the goal to validate a discrete energy law interferes with the goal to validate a contraction property at this point. The fixed-point algorithm, Algorithm A1, together with a stopping criterion, is proposed, and overall convergence of iterates of this fully practical scheme for all discretization, regularization, and thresholding parameters tending to zero is stated in Theorem 4.1. Computational examples addressing both issues related to the given numerical schemes and qualitative behaviors of solutions are reported in Section 5.

2. Preliminaries

Below, unless explicitly stated, always let \( \Omega \subset \mathbb{R}^d \), for \( d = 2, 3 \), be a bounded Lipschitz domain, and let \( p, p_\epsilon \in C(\overline{\Omega}, (1, \infty)) \) satisfy (1.1). The material presented in Section 2.1 can be found in [13, 43].

2.1. Spaces \( L^{p(x)}(\Omega) \) and \( W^{m,p(x)}(\Omega) \). Let \( p \in C(\overline{\Omega}, (1, \infty)) \) be given, with \( p \in [p_-, p_+] \), \( p_+ := \sup_\Omega p \), and let (1.1) be valid. We define the generalized Lebesgue space

\[
L^{p(x)}(\Omega) := \{ u : \Omega \rightarrow \mathbb{R} : u \text{ is a measurable real-valued function,} \rho_{p(x)}(\lambda u) < \infty \text{ for } \lambda > 0 \},
\]

where \( \rho_{p(x)}(u) = \int_\Omega |u|^{p(x)} \, dx \) is called the modular. We introduce the so-called Luxemburg norm on \( L^{p(x)}(\Omega) \),

\[
\|u\|_{L^{p(x)}} := \inf\{\lambda > 0 : \rho_{p(x)}(\frac{u}{\lambda}) \leq 1\}.
\]

If \( p \) is constant, then the variable exponent Lebesgue spaces coincide with the classical Lebesgue space. For all \( u \in L^{p(x)}(\Omega) \), the following holds:

\[
\min \{\|u\|_{L^{p(x)}}^{p_-}, \|u\|_{L^{p(x)}}^{p_+}\} \leq \rho_{p(x)}(u) \leq \max \{\|u\|_{L^{p(x)}}^{p_-}, \|u\|_{L^{p(x)}}^{p_+}\}.
\]

The tuple \( (L^{p(x)}(\Omega), \| \cdot \|_{L^{p(x)}(\Omega)}) \) is a separable Banach space, and its conjugate space is \( L^{q(x)}(\Omega) \), for \( \frac{1}{q(x)} + \frac{1}{p(x)} = 1 \). Given \( u \in L^{p(x)}(\Omega) \) and \( v \in L^{q(x)}(\Omega) \), it follows that

\[
\left| \int_{\Omega} uv \, dx \right| \leq \left( \frac{1}{p_-} + \frac{1}{q_-} \right)\|u\|_{L^{p(x)}(\Omega)}\|v\|_{L^{q(x)}(\Omega)}.
\]

If \( p_1, p_2 \in C(\overline{\Omega}, (1, \infty)) \), such that \( p_1(x) \leq p_2(x) \) in \( \overline{\Omega} \), then \( L^{p_2(x)}(\Omega) \subset L^{p_1(x)}(\Omega) \), and the embedding is continuous.

The (separable, reflexive) Banach space \( W^{1,p(x)}_0(\Omega) \) is defined by

\[
W^{1,p(x)}_0(\Omega) := \{ u \in L^{p(x)} : \|\nabla u\|_{L^{p(x)}}(\Omega), \ u = 0 \text{ on } \partial \Omega \},
\]

which is endowed with the norm

\[
\|u\|_{W^{1,p(x)}_0} := \|u\|_{L^{p(x)}} + \|\nabla u\|_{L^{p(x)}}.
\]

An equivalent norm of \( W^{1,p(x)}_0(\Omega) \) is given by \( \|\nabla u\|_{L^{p(x)}(\Omega)} \). We have that \( C^\infty_0(\overline{\Omega}) \) is dense in \( W^{1,p(x)}_0(\Omega) \). The embedding \( W^{1,p(x)}_0(\Omega) \subset L^{q(x)}(\Omega) \) is continuous and compact if

\[
1 < q(x) \leq \sup_{\Omega} q(x) < \inf_{\Omega} p_+(x) \quad \text{with} \quad p_+(x) = \begin{cases} \frac{dp(x)}{d-p(x)} & d \neq p(x), \\ \infty & p(x) > d. \end{cases}
\]
Moreover, \[ \| u \|_{L^p(\Omega)} \leq C \| \nabla u \|_{L^p(\Omega)} \quad \forall u \in W^{1,p(x)}_0(\Omega). \]

We define the \( p(x) \)-Laplace operator \( -\Delta_{p(x)} u := -\text{div}(|\nabla u|^{p(x)-2}\nabla u) \): it is the derivative of the strictly convex functional \( E_p(u) : W^{1,p(x)}_0(\Omega) \to \mathbb{R} \) given in (1.3).

The mapping \( -\Delta_{p(x)} : W^{1,p(x)}_0(\Omega) \to (W^{1,p(x)}_0(\Omega))^* \) is continuous, bounded, and strictly monotone [11].

2.2. Weak solution of (1.2). Let \( f : \Omega \to \mathbb{R} \) be a continuous function satisfying the growth condition
\[ |f(x,s)| \leq h_f(x) + C_1|s|^\gamma -1 \quad \forall (x,s) \in \Omega \times \mathbb{R}, \]
for some \( \gamma > 1 \), and \( h_f \in L^\infty(\Omega; \mathbb{R}^+) \). In the following, we define weak solutions to (1.2).

**Definition 2.1.** Fix \( T > 0 \), and let \( \Omega \subset \mathbb{R}^d \) be a bounded Lipschitz domain. Let \( p \in C(\overline{\Omega}, (1, \infty)) \) be such that (1.1) holds, and \( (u_0, v_0) \in W^{1,p(x)}(\Omega) \times L^2(\Omega) \). Then \( u : \Omega \times [0,T] \to \mathbb{R} \) is called a weak solution to (1.2) \((\alpha > 0)\) if
(i) \( u \in L^\infty(0,T; W^{1,p(x)}(\Omega)) \cap W^{1,\infty}(0,T; L^2(\Omega)) \cap W^{1,2}(0,T; W^{1,2}_0(\Omega)) \),
(ii) initial data are attained, i.e., for \( t \to 0 \),
\[ u(t,\cdot) \to u_0 \quad \text{in} \ W^{1,p(x)}(\Omega), \quad u_t(t,\cdot) \to v_0 \quad \text{in} \ L^2(\Omega), \]
(iii) for all \( \xi \in C^\infty_0((0,T) \times \Omega) \) it follows that
\[
\int_{\Omega_T} [-u_t\xi_t + |\nabla u|^{p(x)-2}\nabla u \cdot \nabla \xi + \alpha \nabla u_t \cdot \nabla \xi] \, dx \, dt = \int_{\Omega} v_0 : \xi(0,\cdot) \, dx - \int_{\Omega_T} f(x,u)\xi \, dx \, dt,
\]
(iv) for almost every \( t \in [0,T] \),
\[
E_p[u(t,\cdot),u_t(t,\cdot)] - E_p[u_0,v_0] \leq -\alpha \int_{0}^{t} \int_{\Omega} |\nabla u_t|^2 \, dx \, dt.
\]

2.3. Discretization in time and space. Let \( T_h \) be a quasi-uniform triangulation of a polygonal or polyhedral domain \( \Omega \subset \mathbb{R}^d \), \( d = 2,3 \) into triangles or tetrahedra of maximal diameter \( h > 0 \), i.e., \( \Omega = \bigcup_{K \in T_h} K \). Let \( N_h = \{ x_k \}_{k \in L} \) denote the set of all nodes of \( T_h \). Let \( V_h = \{ U \subset C(\overline{\Omega}) : U \text{ is affine on } K, \forall K \in T_h \} \) be the finite element space, and recall the nodal interpolation operator \( I_h : C(\overline{\Omega}) \to V_h \), such that \( I_h \psi = \sum_{z \in N_h} \psi(z) \phi_z \); here, \( \{ \phi_z : z \in N_h \} \subset V_h \) denotes the nodal basis for \( V_h \), and \( \psi \in C(\overline{\Omega}) \). Moreover, we use the \( L^2(\Omega) \)-orthogonal projection \( P_h : L^2(\Omega) \to V_h \); i.e., for every \( \varphi \in L^2(\Omega) \) there exists a unique \( P_h \varphi \in V_h \), satisfying \( \langle \varphi - P_h \varphi, \psi \rangle = 0 \) for all \( \psi \in V_h \).

Given a time-step size \( h > 0 \), and a sequence \( \{ \varphi^j \} \) in some Banach space \( X \), we set \( d_t \varphi^j := k^{-1} \{ \varphi^j - \varphi^{j-1} \} \) for \( j \geq 1 \), and \( d_t^2 \varphi^j := d_t(d_t \varphi^j) = k^{-2} \{ \varphi^j - 2\varphi^{j-1} + \varphi^{j-2} \} \) for \( j \geq 2 \). Note that \( d_t^2 \varphi^j, \varphi^j \) = \( \frac{1}{2} d_t \| \varphi^j \|^2 + \frac{1}{2} \| d_t \varphi^j \|^2 \) if \( X \) is a Hilbert space. Piecewise constant interpolations of \( \{ \varphi^j \} \) are defined for \( t \in [t_j, t_{j+1}) \), and \( 0 \leq j \leq J - 1 \) by \( \varphi^-(t) := \varphi^j \) and \( \varphi^+(t) := \varphi^{j+1} \).
and a piecewise affine interpolation on \([t_j, t_{j+1})\) is defined by
\[
\varphi(t) := \frac{t - t_j}{k} \varphi^{j+1} + \frac{t_{j+1} - t}{k} \varphi^{j}.
\]
Then \(\|\phi^\pm - \phi\|_X \leq 2k \|d_t \phi\|_X\).

3. An implicit finite element discretization of (1.2)

In the following, let \((U^0, V^0) \equiv (P_{L^2} u_0, P_{L^2} v_0) \in [V_h]^2\), and \(U^{-1} := U^0 - kV^0\).
The main goal in this section is to show that iterates of Scheme A below exist, satisfy a discrete energy law, and converge to weak solutions of (1.2) in the sense of Definition 2.1 for discretization, regularization, and perturbation parameters tending to zero.

**Scheme A.** Let \(U^{-1}, U^0 \in V_h\) be given. For every \(1 \leq j \leq J\), find \(U^j \in V_h\) such that for all \(W \in V_h\),
\[
(d_t^j U^j, W) + \left( ||\nabla U^j||^2 + \delta(x) \right) \frac{dH}{\delta} \nabla U^j, \nabla W \right) + \alpha \left( \nabla d_t U^j, \nabla W \right) + \left( \tilde{f}(x, U^j, U^{j-1}), W \right) = 0,
\]
for some \(\delta \in L^\infty(\Omega, [0,1])\), a function \(p_c \in C(\overline{\Omega}, (1,\infty))\) approximating \(p\), and
\[
\tilde{f}(x, a, b) = \left\{ \begin{array}{cl}
F(x, a) & \text{if } a \neq b, \\
\frac{F(x, a) - F(x, b)}{a - b} & \text{if } a = b.
\end{array} \right.
\]

The latter construction is to validate a discrete energy inequality for iterates \((U^j, V^j) := (U^j, d_t U^j)\) (1 \(\leq j \leq J\)) solving (3.1), where \((\varphi, \psi) \in V_h\)
\[
E^\delta_{p_c} [\varphi, \psi] := \int_\Omega \left[ \frac{F(x,a) - F(x,b)}{a - b} \right] \nabla \varphi(x) \nabla \psi(x) + \frac{1}{2} \nabla \varphi^2 + 2 \|
In a first step, we show the well-posedness of Scheme A and the convergence of iterates to weak solutions of (1.2) for \((k, h, \delta, p_c, p) \to 0\) for finite initial energies, provided that \(1 < \gamma < p_\ast\), for \(p_\ast \geq 2\).

**Theorem 3.1.** Let \(T \geq 0\), \(\Omega \subset \mathbb{R}^d\), \(d = 2, 3\) be a bounded Lipschitz domain, \(\alpha \geq 0\), and \(p \in C(\overline{\Omega}, (1,\infty))\) such that (1.1) holds. Assume that \(U^0 \to u_0\) in \(W_0^{1,p(\Omega)}\), and \(V^0 \to v_0\) in \(L^2(\Omega)\) for \(h \to 0\), and let \(f : \Omega \times \mathbb{R} \to \mathbb{R}\) be a continuous function which satisfies (2.8), with
\[
1 < \gamma < p_\ast.
\]

(i) For sufficiently small \(k, h > 0\), \(\delta \in L^\infty(\Omega, [0,1])\), and given \(p_c \in C(\overline{\Omega}, (1,\infty))\), which satisfies (1.1) for every \(\epsilon \geq 0\), and
\[
p_c(x) \geq p(x) \text{ in } \Omega, \quad \text{such that } \|p - p_c\|_{L^\infty(\Omega)} \leq \epsilon,
\]
there exists \(\{U^j\}_{j=1}^J \subset V_h\) which solves (3.1) and satisfies the discrete energy inequality
\[
E^\delta_{p_c} [U^j, V^j] + \frac{k^2}{2} \sum_{l=1}^{j} \|d_t^l U^f\|^2_2 \leq E^\delta_{p_c} [U^0, V^0] \quad (1 \leq j \leq J).
\]
(ii) Let \( \alpha > 0 \) and \( p_- \geq 2 \). For every \( t \in [t_{j-1}, t_j) \) (1 \( \leq j \leq J \)), and

\[
U(t, \cdot) = U_{k,h,\delta(x),\epsilon}(t, \cdot) := \frac{t - t_{j-1}}{k} U_j + \frac{t_j - t}{k} U_{j-1} \quad \text{in } \Omega,
\]

there exist a convergent subsequence \( \{U_j\} \), and \( u \in L^\infty(0, T; W^{1,p(x)}_0(\Omega)) \), such that

\[
U \xrightarrow{\ast} u \quad \text{in } L^\infty(0, T; W^{1,p(x)}(\Omega)) \quad (k, h, \delta(x), \epsilon) \to 0.
\]

Moreover, \( u : \Omega_T \to \mathbb{R} \) is a weak solution of (1.2) in the sense of Definition 2.4.

**Remark 1.** Let \( f(x,u) = -|u|^{\gamma-2}u \), and \( p \geq 2 \) be constant in (1.2). (i) Assume \( \alpha = 0 \). If \( \gamma > p \), solutions with negative initial energy blow up in finite time [31, 25]. (ii) The same behavior is known for \( \alpha > 0 \); see [31, 25].

The proof is split into two parts, where the first addresses existence of solutions \( \{U^j\}_{1 \leq j \leq J} \subset V_h \) of Scheme A, as well as the discrete energy inequality (3.5); the second part verifies convergence of iterates towards weak solutions for \((k, h, \delta(x), \epsilon) \to 0\).

**Proof (Theorem 3.1 part (i)).** Step 1. Existence of sequences \( \{U^j\}_{j=1}^J \subset V_h \) that solve (3.1). For every \( k, h > 0 \), and \( p_- > 1 \), solutions \( U^j \in V_h \) of Scheme A minimize the continuous functional \( E_{k,h}^j : V_h \to \mathbb{R} \), with \( j \geq 1 \)

\[
E_{k,h}^j[W] := \int_{\Omega} \frac{1}{\gamma^2} ||W - 2U_j - U_{j-1}||^2 + \frac{1}{p_+(x)} (|\nabla W|^2 + \delta(x))^{\frac{p_+(x)}{2}} \\
+ \frac{\alpha}{2k} ||\nabla(W - U_{j-1})||^2 + \frac{1}{\theta} F(x, \theta W + (1 - \theta)U_{j-1}) \
\]

for some \( \theta \in (0, 1) \). Here, we use the fact that \( \tilde{f}(x, a, b) = f(x, \theta a + (1 - \theta)b) \) for some \( \theta \in (0, 1) \). In order to bound the last term in (3.4), we recall (2.3) and use Poincaré’s and Young’s inequalities to find

\[
\int_{\Omega} |F(x, W)| \, dx = \int_{\Omega} \int_0^W f(x, s) \, ds \, dx \\
\leq \int_{\Omega} \int_0^W \left[ C_1 s^{\gamma-1} + h_f(x) \right] \, ds \, dx \\
\leq C_1 \gamma ||W||_{L^\gamma} + ||h_f||_{L^\infty} ||W||_{L^1} \\
\leq C \left[ C_1 + 1 \right] ||\nabla W||_{L^\gamma} + ||h_f||_{L^\infty}^{-\frac{1}{\gamma}}.
\]

Since \([p_+]_\gamma > \gamma\), there exists a constant \( \overline{C} = \overline{C}(h_f) > 0 \), such that

\[
\int_{\Omega} |F(x, W)| \, dx \leq \overline{C} + \int_{\Omega} \frac{1}{2p_+(x)} (|\nabla W|^2 + \delta(x))^{\frac{p_+(x)}{2}} \, dx.
\]

Hence, we may conclude coercivity of \( E_{k,h}^j : V_h \to \mathbb{R} \), and hence existence of a (unique) minimizer \( U^j \in V_h \).

**Step 2. Discrete energy estimate (3.5).** Choose \( W = d_t U^j \) in (3.1). Then a convexity argument and summation over all \( 1 \leq \ell \leq j \) lead to the discrete energy
inequality

\[ E^{\delta}_{p_{\epsilon}}[U^j, V^j] + \frac{k^2}{2} \sum_{l=1}^{j} \|d_l V^j\|_{L^2}^2 \]

(3.8)

\[ + \alpha \sum_{l=1}^{j} \|\nabla V^j\|_{L^2}^2 \leq E^{\delta}_{p_{\epsilon}}[U^0, V^0] \quad (1 \leq j \leq J). \]

Since \( F(x, U^j) = \int_{0}^{U^j} f(x, s) \, ds \), by the growth condition (2.3), and Sobolev embedding, we obtain

\[ \int_{\Omega} |F(x, U^j)| \, dx \leq \|h_f\|_L \int_{\Omega} |U^j|_{L^\gamma} + C_1 \|U^j\|_{L^\gamma}. \]

Since \( [p_{\epsilon}]_\gamma > \gamma \), we may proceed as in (3.7) and obtain from (3.8)

\[ \frac{1}{2} \int_{\Omega} \left[ \frac{1}{p_{\epsilon}(x)} \left[ |\nabla U|^2 + \delta(x)^{\frac{p_{\epsilon}(x)-2}{2}} \nabla U, \nabla W \right] \right] \, dx \]

(3.9)

\[ + \frac{k}{2} \sum_{l=1}^{j} \int_{\Omega} \left[ k|d_l V^j|^2 + \alpha |\nabla V^j|^2 \right] \, dx \leq E^{\delta}_{p_{\epsilon}}[U^0, V^0] + C. \]

\[ \square \]

We use \( V^j = d_t U^j \in V_h \) to restate (3.1) in the following way:

(3.10)

\[ (d_t V^j, W) + \left( \left[ |\nabla U|^2 + \delta(x)^{\frac{p_{\epsilon}(x)-2}{2}} \nabla U, \nabla W \right] \right) \]

\[ + \alpha (\nabla d_t U^j, \nabla W) + \left( f(x, U^j, U^{j-1}), W \right) = 0, \]

(3.11)

\[ (V^j, \Psi) - (d_t U^j, \Psi) = 0, \]

for all \((W, \Psi) \in [V_h]^2\). This formulation of the problem leads to the following result.

**Lemma 3.1.** Let \( \{U^j\}_{j \geq -1} \subset V_h \) solve Scheme A. For all \( T > 0 \), and \( \Psi \in W^{1,1}(0, T; V_h) \cap L^2(0, T; V_h) \), it follows that

(3.12)

\[ \left| \int_{0}^{T} (-\langle U_t, \Psi_t \rangle + \left( \left[ |\nabla U|^2 + \delta(x)^{\frac{p_{\epsilon}(x)-2}{2}} \nabla U, \nabla \Psi \right] \right) \right) \, ds + \left( V(T, \cdot), \Psi(T, \cdot) \right) - \left( V(0, \cdot), \Psi(0, \cdot) \right) \right| \]

\[ \leq \left| \int_{0}^{T} \left( \left[ |\nabla U|^2 + \delta(x)^{\frac{p_{\epsilon}(x)-2}{2}} \nabla U - |\nabla U^+|^2 + \delta(x)^{\frac{p_{\epsilon}(x)-2}{2}} \nabla U^+, \nabla \Psi \right] \right) \, ds \right| \]

\[ + \left| \int_{0}^{T} (V - V^+, \Psi_t) \, ds \right| + \left| \int_{0}^{T} \left( f(x, U) - \tilde{f}(x, U^+, U^-), \Psi \right) \, ds \right|. \]
Proof. We rewrite (3.10) as follows: for all \( \Psi, \Phi \in W^{1,1}(0, T; V_h) \cap L^2(0, T; V_h) \),

\[
\int_0^T \left[ (V_t, \Psi) + \left( \|\nabla U^+\|^2 + \delta(x) \right)^{\frac{p-2}{2}} \nabla U^+, \nabla \Psi \right] dt = 0, 
\]

\[
\int_0^T \left[ (V^+, \Psi) - (U_t, \Psi) \right] dt = 0. 
\]

Integration by parts in time in the first term in (3.10) yields

\[
\int_0^T (V_t, \Psi) dt = - \int_0^T (V, \Psi_t) dt + (V(T, \cdot), \Psi(T, \cdot)) - (V(0, \cdot), \Psi(0, \cdot))
\]

\[
= - \int_0^T (U_t, \Psi_t) dt - \int_0^T (V^+ - V, \Psi_t) dt 
+ (V(T, \cdot), \Psi(T, \cdot)) - (V(0, \cdot), \Psi(0, \cdot)),
\]

thanks to (3.14). Putting things together verifies the assertion of the lemma. \( \square \)

The following result gives uniform bounds for \( \{V\} \).

**Lemma 3.2.** Suppose that the assumptions of Theorem 3.1 (ii) are valid. Then

\[
\|V\|_{L^2(0, T; W^{1,1})} + \|V\|_{L^2(0, T; W^{1,2})} \leq C.
\]

**Proof.** We use (3.13), and employ \( W^{1,p}\)-stability of \( P_{L^2} \), see [9] Theorems 3 & 4], to conclude

\[
\|V_t(s, \cdot)\|_{W^{1,1}[p^{-1}]} := \sup_{\varphi \in W^{1,1}[p^{-1}]} \frac{(V_t(s, \cdot), P_{L^2} \varphi)}{\|\varphi\|_{W^{1,1}[p^{-1}]}} 
\leq C \left[ \|\nabla U^+(s, \cdot)\|_{L^p}^{p-1} + \|\nabla U_t(s, \cdot)\|_{L^2} + \|U(s, \cdot)\|_{L^p}^{p-1} + 1 \right].
\]

Estimate (3.9) then implies the first part of the assertion. The second part follows from (3.9) and

\[
\|V\|_{L^2(0, T; W^{1,2})} \leq \|V^-\|_{L^2(0, T; W^{1,2})} + \|V^+\|_{L^2(0, T; W^{1,2})}.
\]

\( \square \)

**Proof (Theorem 3.1 part (ii)).** Step 3. Passing to the limit \( (k, h, \delta(x), \epsilon) \to 0 \) in (3.1). It follows from (3.9) that there exist

\[
u \in L^\infty(0, T; W^{1,1}_0(\Omega)) \cap W^{1,\infty}(0, T; L^2(\Omega)) \cap W^{1,2}(0, T; W^{1,2}_0(\Omega)),
\]

and a convergent subsequence of \( \{U\}_{k,h,\delta(x),\epsilon} \) such that for \( (k, h, \delta(x), \epsilon) \to 0 \),

\[
U \rightharpoonup u \quad \text{in } L^\infty(0, T; W^{1,1}_0(\Omega)) \cap W^{1,\infty}(0, T; L^2(\Omega)),
\]

\[
U \rightharpoonup u \quad \text{in } W^{1,2}(0, T; W^{1,2}_0(\Omega)),
\]

\[
\|\nabla U^+\|^2 + \delta \|U^+\|^{p-2}_x \nabla U^+ \rightharpoonup b \quad \text{in } L^\infty(0, T; L^{\alpha/3}(\Omega)),
\]

\[
V \rightharpoonup u_t \quad \text{in } W^{1,2}(0, T; W^{1,2}_0(\Omega)) \cap L^2(0, T; W^{1,2}_0(\Omega)),
\]

\[
U, U^+, U^- \rightharpoonup u \quad \text{in } W^{1,2}(0, T; L^2(\Omega)),
\]

\[
f(\cdot, U), f(\cdot, U^+, U^-) \rightharpoonup f(\cdot, u) \quad \text{in } L^{\frac{\alpha}{\alpha-1}}(\Omega_T),
\]

\[
\lim_{(k, h, \delta(x), \epsilon) \to 0} \frac{1}{(k, h, \delta(x), \epsilon)} \int_0^T \int_{\Omega} \left[ (V_t, \Psi) + \left( \|\nabla U^+\|^2 + \delta(x) \right)^{\frac{p-2}{2}} \nabla U^+, \nabla \Psi \right] dt ds 
= \int_0^T \int_{\Omega} \left[ \left( \frac{1}{\epsilon}\nabla U^+ \right)^{\frac{p-2}{2}} \nabla U^+, \nabla \Psi \right] dt ds.
\]
thanks to (3.5) and Lemma 3.2; property (3.13) is a consequence of the control
\[\|V^+ - V\|_{L^2(\Omega_T)} \leq \sqrt{k} \|V_t\|_{L^2(\Omega_T)} \leq \sqrt{k} E_{p^*}^\delta [U_0, V_0],\]
and follows from the Aubin-Lions compactness result. Property (3.13) is a consequence
of the following bound, which is uniform in \((k, h, \delta(x), \epsilon)\):
\[\int_{\Omega_T} |f(\cdot, U)|^{p^*} \ dx \ dt \leq C,\]
thanks to \(\gamma < p_-, \) and (3.15); the second property here uses \(\hat{f}(\cdot, U^+, U^-) = f(\cdot, \theta U^+ + (1 - \theta) U^-)\) for some \(\theta \in (0, 1)\).

We can now identify limits in (3.12): let \(\Psi = I_h \xi(t, \cdot)\) for \(\xi \in C^\infty_0([0, T) \times \Omega)\). Thanks to \([\text{Id} - I_h] \xi(t, \cdot) \to 0\) in \(C^\infty_0(\Omega)\) \((h \to 0)\) for every \(t \in [0, T]\), and (3.13), (3.10), the right-hand side of (3.12) vanishes for \((k, h, \delta(x), \epsilon) \to 0\), and we obtain
\[\int_0^T \left[-(u_t, \xi_t) + (b, \nabla \xi) + \alpha (\nabla u_t, \nabla \xi) + (f(x, u), \xi)\right] \ dx \ dt = (v_0, \xi(0, \cdot)),\]
\(\forall \xi \in C^\infty_0([0, T) \times \Omega).\)

It remains to show that \(b = |\nabla u|^{p(x)-2} \nabla u\). For this purpose, monotonicity of \(-\Delta_p(x) : W_0^{1,p(x)}(\Omega) \to [W_0^{1,p(x)}(\Omega)]^*\) implies \(\left(\|\nabla U^+\|^2 + \delta \frac{p(x)-2}{2} \|\nabla U^+\|^2 + \delta \frac{p(x)-2}{2} \nabla I_h \xi^+, \nabla [U^+ - I_h \xi^+]\right) \geq 0,\)
for every \(W(t, \cdot) = [U^+ - I_h \xi^+](t, \cdot) \in V_h, \) where \(\xi \in C^\infty_0([0, T) \times \Omega).\) We use equation (3.13) to conclude from this inequality that
\[\int_0^T \left[-(\hat{f}(\cdot, U^+, U^-), U^+ - I_h \xi^+) - (V_t, U^+ - I_h \xi^+) - \alpha (\nabla U_t, \nabla [U^+ - I_h \xi^+])\right.\]
\[\left. - \left(\|\nabla I_h \xi^+\|^2 + \delta \frac{p(x)-2}{2} \nabla I_h \xi^+, \nabla [U^+ - I_h \xi^+]\right)\right] \ dx \ dt \geq 0.\]
Passing to the limit \((k, h, \delta(x), \epsilon) \to 0,\) and again using (3.13), (3.17), together with \([\text{Id} - I_h] \xi(t, \cdot) \to 0\) \((h \to 0)\) in \(W^{1,\infty}(\Omega)\) then yields
\[\int_0^T \left(b - |\nabla \xi|^{p(x)-2} \nabla \xi, \nabla [u - \xi]\right) \ dx \ dt \geq 0, \quad \forall \xi \in C^\infty_0([0, T) \times \Omega).\]
Here, we use the following property, which employs \(W^{1,\infty}(\Omega)\)-stability of the Lagrange interpolation operator,
\[\left\|\nabla I_h \xi^+|^{p(x)-2} (1 - |\nabla I_h \xi^+|^{p(x)-p(x)}) \nabla I_h \xi^+\right\|_{L^1} \leq C (1 + \|\nabla \xi^+\|_{L^\infty})^{p^* - 1} \left\|1 - |\nabla I_h \xi^+|^{p(x)-p(x)}\right\|_{L^1}.
We split the second factor as follows:
\[\left[\int_{\{ |\nabla I_h \xi^+| \leq 2 \}} + \int_{\{ |\nabla I_h \xi^+| > 2 \}} \right] |1 - |\nabla I_h \xi^+|^{p(x)-p(x)}| \ dx.\]
Convergence to zero of the first term for \(\epsilon \to 0\) is immediate; for the second term, we calculate that
\[\int_{\{ |\nabla I_h \xi^+| > 2 \}} \left|1 - \exp\left(\epsilon \ln\left[|\nabla I_h \xi^+|\right]\right)\right| \ dx \to 0 \quad (\epsilon \to 0).\]
Let us come back to (3.18): Choosing \( \xi = u \pm \alpha \zeta \), and letting \( \alpha \to 0 \), we employ monotonicity of \( \Delta_{p(x)} : W^{1,p(x)}_0(\Omega) \to [W^{1,p(x)}_0(\Omega)]^* \) to conclude that

\[
\int_0^T \left( b - |\nabla u|^{p(x)-2}\nabla u, \nabla \zeta \right) dt = 0 \quad \forall \zeta \in C_0^\infty([0, T) \times \Omega),
\]

which validates \( b = |\nabla u|^{p(x)-2}\nabla u \). This identification in (3.17) verifies property (iii) of Definition 2.1.

Properties (ii), resp. (iii), of Definition 2.1 are now immediate consequences of (i), resp. (3.5).

\[\square\]

Remark 1. Suppose that \( F : \Omega \times \mathbb{R} \to \mathbb{R} \) is convex in the second argument. Then we can use the following discretization instead of (3.1):

\[
(3.19) \quad (d_t^2U^j, W) + \left( |\nabla U^j|^2 + \delta(x) \right)^{\frac{p(x)-2}{2}} \nabla U^j, \nabla W \right) 
\]

\[\quad + \alpha \left( \nabla d_t U^j, \nabla W \right) + \left( f(x, U^j), W \right) = 0,
\]

for all \( W \in V_h \). In this case, existing solutions \( \{U^j\}_j \subset V_h \) minimize (3.6), with \( \theta = 1 \), and satisfy (3.5) as well.

2. For general continuous \( f : \Omega \times \mathbb{R} \to \mathbb{R} \), we may employ scheme (3.19) as well, or the following semi-implicit variant,

\[
(3.20) \quad (d_t^2U^j, W) + \left( |\nabla U^j|^2 + \delta(x) \right)^{\frac{p(x)-2}{2}} \nabla U^j, \nabla W \right) 
\]

\[\quad + \alpha \left( \nabla d_t U^j, \nabla W \right) + \left( f(x, U^{j-1}), W \right) = 0,
\]

for all \( W \in V_h \). However, in both cases, (3.3) has to be sharpened to \( \gamma \leq \frac{p(x)}{p-1} + 1 \), and the discrete energy inequality (3.5) does not hold any more. The reason for this comes from the following modifications of (3.8) (1 \( \leq j \leq J \)):

\[
(3.21) \quad \max_{1 \leq \ell \leq j} \left[ \frac{1}{2} \|V^\ell\|_{L^2}^2 + \int_\Omega \frac{1}{p(x)} \left( |\nabla U^\ell|^2 + \delta(x) \right)^{\frac{p(x)}{2}} dx \right] 
\]

\[\quad + \frac{k^2}{2} \sum_{\ell=1}^j \|d_t V^\ell\|_{L^2}^2 + \alpha k \sum_{\ell=1}^j \|\nabla V^\ell\|_{L^2}^2 
\]

\[\quad \leq \frac{1}{2} \|V^0\|_{L^2}^2 + \int_\Omega \frac{1}{p(x)} \left( |\nabla U^0|^2 + \delta(x) \right)^{\frac{p(x)}{2}} dx + k \sum_{\ell=1}^j \|f(x, U^\ell), V^\ell)\|.
\]

We use Young’s inequality and (2.3) to bound the last term as follows:

\[\leq k \sum_{\ell=1}^j \|f(x, U^\ell)\|_{L^{2(p-1)}} \|V^\ell\|_{L^{2p}} \leq k \sum_{\ell=1}^j \left[ C\alpha \|U^\ell\|_{L^{2(p-1)}}^{2(\gamma-1)} + \frac{\alpha}{2} \|\nabla U^\ell\|_{L^{2p}}^2 \right],
\]

where we put \( h_f \equiv 1 \) in (2.3) for simplicity. Hence, in order to use the discrete version of Gronwall’s lemma, we need \( \gamma \geq 1 \).

4. A simple fixed point scheme to solve Algorithm A

For every \( j \geq 1 \) in Scheme A, a nonlinear algebraic equation has to be solved: a simple fixed point strategy, together with a stopping criterion, could be as follows.
Algorithm \textbf{A}. Let $U^0 \in V_h$, $V^0 := d_0U^0 \in V_h$, and set $j := 1$.
1. Set $U^{j,0} := U^{j-1}$ and $\ell = 0$.
2. Compute $U^{j,\ell} \in V_h$ such that for all $W \in V_h$,
\begin{align}
\left( \frac{U^{j,\ell} - U^{j-1}}{k^2}, W \right) + \left( \left\| \frac{\alpha}{k} \frac{(\nabla U^{j,\ell-1})^2 + \delta(x)}{2} \nabla U^{j,\ell} \right\|^{\frac{\alpha}{k}}_L, \nabla W \right) \\
+ \alpha \frac{1}{k} (\nabla U^{j,\ell} - U^{j-1}, \nabla W) + \left( f(x, U^{j,\ell-1}, U^{j-1}), W \right) = \frac{1}{k} (d_\ell U^{j-1}, W).
\end{align}
(4.1)

3. For fixed $\theta > 0$, stop if
\begin{align}
\left\| \left( \frac{\alpha}{k} \frac{(\nabla U^{j,\ell-1})^2 + \delta(x)}{2} \nabla U^{j,\ell} - \left( \left\| \frac{\alpha}{k} \frac{(\nabla U^{j,\ell-1})^2 + \delta(x)}{2} \nabla U^{j,\ell} \right\|^{\frac{\alpha}{k}}_L, \nabla \right) \right) \right\|_{L^2} \\
+ \left\| f(x, U^{j,\ell-1}) - f(x, U^{j-1}) \right\|_{L^2} \leq \theta,
\end{align}
(4.2)

set $U^j := U^{j,\ell}$, $j := j + 1$, and go to Step 1.
4. Set $\ell := \ell + 1$, and go to Step 2.

Unfortunately, it is not clear whether a contraction property holds, the reason being the modified nonlinearity $\tilde{f}$. For this reason, we base the following algorithm on discretization (3.19); see Remark \textbf{2} which discusses existence of solutions for monotone $f$, or more general situations, where (2.3) holds for some $1 \leq \gamma < \frac{1}{2}$, and thus allows for convergence of iterates towards weak solutions of (1.2) in the sense of Definition \textbf{2.1}.

Algorithm \textbf{A}. Let $U^0 \in V_h$, $V^0 := d_0U^0 \in V_h$, and set $j := 1$.
1. Set $U^{j,0} := U^{j-1}$ and $\ell = 0$.
2. Compute $U^{j,\ell} \in V_h$ such that for all $W \in V_h$,
\begin{align}
\left( \frac{U^{j,\ell} - U^{j-1}}{k^2}, W \right) + \left( \left\| \frac{\alpha}{k} \frac{(\nabla U^{j,\ell-1})^2 + \delta(x)}{2} \nabla U^{j,\ell} \right\|^{\frac{\alpha}{k}}_L, \nabla W \right) \\
+ \alpha \frac{1}{k} (\nabla U^{j,\ell} - U^{j-1}, \nabla W) + \left( f(x, U^{j,\ell-1}, U^{j-1}), W \right) = \frac{1}{k} (d_\ell U^{j-1}, W).
\end{align}
(4.3)

3. For fixed $\theta > 0$, stop if
\begin{align}
\left\| \left( \frac{\alpha}{k} \frac{(\nabla U^{j,\ell-1})^2 + \delta(x)}{2} \nabla U^{j,\ell} - \left( \left\| \frac{\alpha}{k} \frac{(\nabla U^{j,\ell-1})^2 + \delta(x)}{2} \nabla U^{j,\ell} \right\|^{\frac{\alpha}{k}}_L, \nabla \right) \right) \right\|_{L^2} \\
+ \left\| f(x, U^{j,\ell-1}) - f(x, U^{j-1}) \right\|_{L^2} \leq \theta,
\end{align}
(4.4)

set $U^j := U^{j,\ell}$, $j := j + 1$, and go to Step 1.
4. Set $\ell := \ell + 1$, and go to Step 2.

Below, we validate overall convergence to weak solutions of (1.2) in the sense of Definition \textbf{2.1}. For this purpose, we assume that $f$ is differentiable with respect to its second argument, and for some $1 < r < \infty$,
\begin{align}
\left| \frac{\partial}{\partial s} f(x, s) \right| \leq C (1 + |s|^r) \quad \forall x \in \Omega. 
\end{align}
(4.5)

Theorem 4.1. Suppose that the assumptions of Theorem \textbf{5.1} are valid, $\alpha > 0$, and (3.19) holds. Let $\delta \in C(\Omega, [0,1])$ such that $\delta(x) > 0$ if $p \equiv p(x) < 3$, and $\delta(x) = 0$ otherwise. For all $\ell \geq 0$, there exists a unique solution $U^{j,\ell} \in V_h$ to (4.3).
Moreover, there exists $\tilde{C} \equiv \tilde{C}(d, r, \Omega) > 0$ such that if for all $1 \leq j \leq J$ it follows that

$$
\alpha^2 k^2 h^{-dr} + \chi(2 \leq p_r(\cdot) \leq 3) \left[ \max_{2 \leq p_r(\cdot) \leq 3} \left[ \frac{\rho_r(\cdot)}{p_r(\cdot) - 3} h^{-[d+2]} \right] \right]
+ \max_{2 \leq p_r(\cdot) \leq 3} h^{-[d+2][p_r(\cdot) - 2]} + \chi(p_r(\cdot) > 3) h^{-[d+2][p_r(\cdot) - 2]} < \tilde{C}^{-1} k^{-2} \alpha^2,
$$

(4.6)

then $(\ell \geq 1)$

$$
\left( \|U^{j, \ell+1} - U^{j, \ell}\|_{L^2}^2 + \alpha k \|\nabla(U^{j, \ell+1} - U^{j, \ell})\|_{L^2}^2 \right) \leq q \left( \|U^{j, \ell} - U^{j, \ell-1}\|_{L^2}^2 + \alpha k \|\nabla(U^{j, \ell} - U^{j, \ell-1})\|_{L^2}^2 \right)
$$

where $q < 1$.

Finally, let either $F : \Omega \times \mathbb{R} \to \mathbb{R}$ be convex in the second argument, or else $\gamma \leq \frac{p}{2} + 1$. Then iterates \{U^{j, \ell}\}_\ell of Algorithm A1 which meet the stopping criterion in Step 3 subconverge to weak solutions of (1.2) in the sense of Definition 2.1 for $(k, h, \delta(x), \epsilon, \theta) \to 0$, as is specified in Theorem 3.1.

Remark 3. In Theorem 4.1 we assume $\alpha > 0$; however, for $\alpha = 0$, a corresponding convergence result can be derived for iterates \{U^{j, \ell}\}_\ell of Algorithm A1 towards solutions $U^j \in V_h$ of Scheme A ($1 \leq j \leq J$), provided a more restrictive mesh constraint than (4.6) holds.

Proof. Step 1. Contraction principle. Let $j \geq 1$ be fixed, and

$$
\rho_r(\nabla U^{j, \ell-1}) + \|d_t U^{j, \ell-1}\|_{L^2}^2 \leq C,
$$

(4.8)

independently of $j$. For every $\ell \geq 1$, existence and uniqueness of a solution $U^{j, \ell} \in V_h$ follow from the Lax-Milgram theorem. To show convergence of \{U^{j, \ell}\}_\ell, we establish an $L^2(\Omega)$-contraction property (4.7). Let $E^{j, \ell} := U^{j, \ell} - U^{j, \ell-1} \in V_h$; we subtract two successive versions of (4.3) and choose $W = E^{j, \ell}$ as a test function,

$$
\frac{1}{2} \left\| E^{j, \ell} \right\|_{L^2}^2 + \frac{\alpha k}{2} \|\nabla E^{j, \ell}\|_{L^2}^2 \leq C k^4 \left[ \left\| f(\cdot, U^{j, \ell-1}) - f(\cdot, U^{j, \ell-2}) \right\|_{L^2}^2 \right] + C \alpha^{-1} k^3 \left[ \|\nabla U^{j, \ell-1}\|_{L^2}^2 + \delta(x) \| \frac{p_r(x)-2}{2} \nabla U^{j, \ell} \|_{L^2}^2 \right]
$$

(4.9)

$$
+ \left[ \|\nabla U^{j, \ell-2}\|_{L^2}^2 + \delta(x) \| \frac{p_r(x)-2}{2} \nabla U^{j, \ell-1} \|_{L^2}^2 \right],
$$

by Young's inequality.

The leading error term on the right-hand side of (4.9) is bounded by an inverse estimate, and (4.5), for some $\xi \in (0, 1),$

$$
\leq C k^4 \left[ 1 + \left\| U^{j, \ell-1} - (1 - \xi) U^{j, \ell-2} \right\|_{L^\infty}^{2r} \right] \left\| E^{j, \ell-1} \right\|_{L^2}^2
$$

$$
\leq C k^4 \left[ 1 + h^{-dr} \left\| U^{j, \ell-1} - (1 - \xi) U^{j, \ell-2} \right\|_{L^2}^{2r} \right] \left\| E^{j, \ell-1} \right\|_{L^2}^2.
$$

Note that $\|U^{j, \ell}\|_{L^2} \leq C$, for all $\ell \geq 0$, which easily follows from choosing $W = U^{j, \ell}$ in (4.3), and using (4.8).
Since $x \mapsto \|x\|^q + \delta(x)$ is differentiable, we then obtain
\[
\|E^{j,\ell}\|_{L^2}^2 + \frac{\alpha^k}{4} \|\nabla E^{j,\ell}\|_{L^2}^2 \leq C k^4 h^{-d r} \|E^{j,\ell-1}\|_{L^2}^2 \\
+ C k^3 \alpha^{-1} \left[ \|\nabla U^{j,\ell-2}\|_{L^2} + \delta(x) \right] \frac{p_0(x)-2}{2} \|\nabla E^{j,\ell-1}\|_{L^2}^2 \\
+ \max_{\zeta \in (\nabla U^{j,\ell-1},\nabla U^{j,\ell-2})} \|p_{\zeta}(x)\|_{L^2} \left( |\zeta|^2 + \delta(x) \right) \frac{p_\zeta(x)-2}{2} \|\nabla E^{j,\ell-1}\|_{L^2}^2.
\]
By an inverse estimate, $\|\nabla U^{j,\ell}\|_{L^\infty} \leq C h^{-[\frac{d+1}{2}]} \|U^{j,\ell}\|_{L^2}$, and (4.8) we obtain
\[
\|E^{j,\ell}\|_{L^2}^2 + \frac{\alpha^k}{4} \|\nabla E^{j,\ell}\|_{L^2}^2 \leq C k^4 h^{-d r} \|E^{j,\ell-1}\|_{L^2}^2 \\
+ C k^3 \alpha^{-1} \|\nabla E^{j,\ell-1}\|_{L^2}^2 \left[ \text{ess sup}_{\Omega} \|\nabla U^{j,\ell-2}\|_{L^2} + \delta(x) \right] \frac{p_0(x)-2}{2} \\
+ \max_{\zeta \in (\nabla U^{j,\ell-1},\nabla U^{j,\ell-2})} \text{ess sup}_{\Omega} |\zeta|^2 + \delta(x) \frac{p_\zeta(x)-2}{2} h^{-[d+2]}.
\]
Hence, (4.9) is sufficient to validate a contraction principle for iterates.

**Step 2: Overall convergence.** The previous step shows that Algorithm $\overline{A}$ terminates. Hence, for every $\theta > 0$, and every $j \geq 1$, there exists $\ell := \ell(j, \theta) < \infty$ such that the stopping criterion is met, and for all $W \in V_h$, we have
\[
(d^2 U^j, W) + \left( (\|\nabla U^j\|_{L^2} + \delta(x)) \frac{p_0(x)-2}{2} \nabla U^j, \nabla W \right) + \left( f(x, U^j), W \right) \\
\leq \left( (\|\nabla U^j\|_{L^2} + \delta(x)) \frac{p_0(x)-2}{2} \nabla U^j, \nabla W \right) - \left( (\|\nabla U^j\|_{L^2} + \delta(x)) \frac{p_\zeta(x)-2}{2} \nabla U^j, \nabla W \right) \\
+ \left( f(x, U^j) - f(x, U^j), W \right).
\]
Because of Step 3 in Algorithm $\overline{A}$, the right-hand side may be bounded by $\theta (\|\nabla W\|_{L^p(\Omega)} + \|W\|_{L^2})$. As a consequence, we may follow the (slightly modified) proof of Theorem 3.4 to conclude subsequence convergence.

Theorem 4.1 specifies situations where Algorithm $A_1$ terminates and motivates combined choices of the regularization function $\delta \in C(\Omega; [0, 1])$, the function $p_\zeta \in C(\Omega; (1, \infty))$, discretization parameters $k, h > 0$, and gives a theoretical indication for the stopping criterion $4.10$.

**5. Computational experiments**

In this section, we report on experiments where we use Algorithm $A_1$, implemented in MATLAB, with a direct solution of linear systems of equations. Below, let $x = (x_1, x_2)$. The function $(x_1, x_2) \mapsto \exp(-(x_1 - 0.5)^2/0.03) \ast \exp(-(x_2 - 0.5)^2/0.03)$ will be referred to as “hat”. All examples use vanishing Neumann boundary conditions, and $\delta = 10^{-7} = \theta$. We typically need 2 or 3 fixed-point iterations per step.

The first example is to study the solution’s behavior for $p_+ / p_- \gg 1$. It also exemplifies the fact that weak solutions to (1.2) for supercritical growth of $f$ exist, provided initial data satisfy a certain smallness condition.

**Example 5.1.** Let $\Omega = (0, 1)^2$, $T = 1$, $\alpha \in (0, 0.25)$, as well as $\nu_0 = 0$, and $u_0 = 2 \ast$ hat. Choose $f(x, u) = -|u|^{\gamma-2} u$, for $\gamma = 5$, and $p(x) = 1 + 2x_1 x_2$. 

Plots for the decaying energy ($\alpha > 0$), resp. constant energy ($\alpha = 0$), are shown in Figure 1. Snapshots of $u$ at times $t = 0.1, 0.4, 0.7, 1$ are given in Figure 2 for $\gamma = 5$. For $\gamma = 1.5$ we experience very similar behavior.

A reverse calculation, started at time $t = T/2$ for the above example with $\alpha = 0$ and $\gamma = 1.5$, recovered the initial data up to an $L^2$-error of $1.3 \times 10^{-3}$, and $L^\infty$-error of $5.4 \times 10^{-3}$.

The following example is to study $L^\infty$-decay of $u$, $u_t$, and $\nabla u$ in time for variable exponents, including a study where $p_- = 0$.

**Example 5.2.** Let $\Omega = (0, 1)^2$, $T = 1$, $\alpha = 1$, as well as $v_0 = 0$, and $u_0 = 0.5 \hat{\text{v}}$. Choose $p_i(x) = i + 2x_1x_2$, for $i \in \{0, 1, 2\}$, and $f(x, u) = |u|^{\gamma - 2}u$, for $\gamma = 6$.

Different decay rates of the energy, as well as the behavior of the $L^\infty$-norms of $u$, $u_t$, and $\nabla u$ are shown in Figure 3 for $p_i(x) = i + 2x_1x_2$, with $i \in \{0, 1, 2\}$.

As the images in the bottom row show, the smaller $p$, the better the initial data are conserved. While $\|u_t\|_{L^\infty}$ for $p(x) = 2x_1x_2$ appears to oscillate, the solution...
Figure 3. Example 5.2. Top row: Energy decay for $i = 0, 1, 2$.
Middle row: $L^\infty$-norms of $u$, $u_t$, and $\nabla u$ (y-axis logarithmically scaled) for $i = 0, 1, 2$. Bottom row: $u$ at $T = 1$ for $i = 0, 1, 2$.

does not show big changes (note, however, that in this case the logarithmic plot makes the oscillations look worse than they are).

Blowup behavior of (local strong) solutions to (1.2) for $\alpha = 0$ has been shown in [22] for nonlinearities where $uf(x, u) \geq (2 + \beta)F(x, u)$, for some $\beta > 0$, $q \equiv 2$, and $E[u_0, v_0] < 0$; in [23], it is shown that weak (nonlinear) damping of the form

$$u_{tt} - \Delta u + |u_t|^{m-2}u_t + f(x, u) = 0 \quad \text{in } \Omega_T$$

is insufficient to prevent the blow-up effect in the following sense: for $f(x, u) = -|u|^{\gamma-2}u$, and $\gamma > m \geq 2$, and negative initial energies, local strong solutions blow up in finite time; i.e., $\lim_{t \to T} \|u(t, \cdot)\|_{L^\infty} = \infty$, for some $0 < T^* < \infty$. Moreover, the solution blowup occurs if and only if the energy blows up; i.e., $\lim_{t \to T} E_p[u(t, \cdot), u_t(t, \cdot)] = -\infty$. (In fact, weak solutions exist if $m \geq \gamma \geq 2$.) In [15], the existence of weak solutions to ($0 < \alpha \leq 1$, and constant $p \geq 2$)

$$u_{tt} - \Delta_p u + (\Delta)^\alpha u_t = |u|^{\gamma-2}u \quad \text{in } \Omega_T,$$

for $\gamma \geq p$ is shown, provided that the initial data are properly chosen; blow-up behavior of solutions in the case of negative initial energies and $\gamma > p \geq 2$ is verified in [31, 25, 16].

Examples 5.3 and 5.4 study related questions for variable exponents: blowup for large initial data, and supercritical growth of $f$, for $\alpha = 1, 0$, respectively.
Example 5.3. Let $\Omega = (0, 1)^2$, $T = 1$, $\alpha = 1$, and $u_0 = 10 \hat{\text{u}}$, $v_0 = 0$. Choose $p = 2$, and $f(x, u) = -|u|^\gamma u$, for $\gamma = 6$.

Figure 4 shows energy blowup (to minus infinity), $L^\infty$-norms of $u$, $u_t$, and $\nabla u$, as well as snapshots of $u$ at times $t = 0.01, 0.015, 0.017, 0.0191$ (left to right).

This example generalizes the Klein-Gordon equation with focusing nonlinearity, $u_{tt} - \Delta u - u^5 = 0$ in $\Omega_T$. In the case of spherically symmetric initial data $(u_0, v_0)$ it is known that solutions for small initial data exist and converge to zero [19], and that large data solutions of negative energy blowup in finite time [22]; see also [21]. As is motivated in [7], the static spherically symmetric solution $f(r) = \frac{1}{\sqrt{1 + r^2}}$ ($r = \sqrt{x_1^2 + x_2^2}$) is a candidate for a blowup with unbounded growth at $r = 0$ at a rate $\frac{1}{\sqrt{1 - t}}$.

Example 5.4. Let $\Omega = (0, 1)^2$, $T = 1$, $\alpha = 0$, and $u_0 = 3 \hat{\text{u}}$, $v_0 = 0$. Choose $p = 3 - 2 \hat{\text{u}}$, and $f(x, u) = -|u|^\gamma u$, for $\gamma = 6$.

Figure 5 shows energy blowup (apparently to plus infinity, but we are not sure whether this is a numerical artifact), $L^\infty$-norms of $u$, $u_t$, and $\nabla u$, as well as snapshots of $u$ at times $t = 0.05, 0.1, 0.15, 0.154$.

Solutions to both numerical schemes as well as the PDE (1.2) use energy-based arguments, which require initial data of finite energy, in particular. In our last example, we evolve initial data of low regularity/infinite energy, which leads to interesting issues concerning locally existing solutions of typical nonlinear equations [24], as well as blowup, as shown in the next example.
Example 5.4. Let $\Omega = (0,1)^2$, $T = 1$, $\alpha = 0$, $v_0 = 0$, and $u_0 = 5$ on $[0.25,0.375]^2 \cup [0.625,0.75]^2$, and zero elsewhere. Let $f(x,u) = |u|^{\gamma-2}u$, for $\gamma = 6$, and $p(x) = 1 + 2x_1x_2$.

Figure 5 shows energy blowup (to plus infinity) for different space discretizations $h = 1/16, 1/32, 1/64$. The qualitative behavior of the solutions for different $h$ seems to be the same. Note, however, that the initial energy for $h = 1/16$ is negative, while it is positive for finer $h$. $L^\infty$-norms of $u$, $u_t$, and $\nabla u$, as well as snapshots of $u$ at times $t = 0.001, 0.04, 0.046, 0.0486$ are given for the finest $h$ only.

Again, we see (compare front and rear bricks) that (locally) smaller $p$ better preserve the structure, while with (locally) larger $p$, the brick crumbles much more. Nevertheless, the large right-hand side ensures that both bricks blow up.
**Figure 6.** Example 5.5: Top row: Energies before blowup (left), energies including blowup (middle, log-plot) for different space discretizations $h = 1/16, 1/32, 1/64$, as well as $L^\infty$-norm plots of $u$, $u_t$, and $\nabla u$ (log-plot) for $h = 1/64$. Middle and bottom rows: Snapshots for $h = 1/64$ and $t = 0.001, 0.04, 0.046, 0.0486$.

Additional examples and short movies of the above computational studies can be found online at [http://na.uni-tuebingen.de/~haehnle/wpx/](http://na.uni-tuebingen.de/~haehnle/wpx/).
