STRONG ORDER OF CONVERGENCE OF A FULLY DISCRETE APPROXIMATION OF A LINEAR STOCHASTIC VOLterra TYPE EVOLUTION EQUATION

MIHÁLY KOVÁCS AND JACQUES PRINTEMS

Abstract. In this paper we investigate a discrete approximation in time and in space of a Hilbert space valued stochastic process \( \{u(t)\}_{t \in [0,T]} \) satisfying a stochastic linear evolution equation with a positive-type memory term driven by an additive Gaussian noise. The equation can be written in an abstract form as

\[
du + \left( \int_0^t b(t-s)Au(s) \, ds \right) \, dt = dW^Q, \quad t \in (0,T]; \quad u(0) = u_0 \in H,
\]

where \( W^Q \) is a \( Q \)-Wiener process on \( H = L^2(D) \) and where the main example of \( b \) we consider is given by

\[
b(t) = t^{\beta-1}/\Gamma(\beta), \quad 0 < \beta < 1.
\]

We let \( A \) be an unbounded linear self-adjoint positive operator on \( H \) and we further assume that there exist \( \alpha > 0 \) such that \( A^{-\alpha} \) has finite trace and that \( Q \) is bounded from \( H \) into \( D(A^\gamma) \) for some real \( \kappa \) with \( \alpha - \frac{1}{\beta+1} < \kappa \leq \alpha \).

The discretization is achieved via an implicit Euler scheme and a Laplace transform convolution quadrature in time (parameter \( \Delta t = T/n \)), and a standard continuous finite element method in space (parameter \( h \)). Let \( u_{n,h} \) be the discrete solution at \( T = n\Delta t \). We show that

\[
\left( \mathbb{E} \| u_{n,h} - u(T) \|^2 \right)^{1/2} = O(h^\nu + \Delta t^\gamma),
\]

for any \( \gamma < (1-(\beta+1)(\alpha-\kappa))/2 \) and \( \nu \leq \frac{1}{\beta+1} - \alpha + \kappa \).

1. Introduction

Let \( \mathcal{D} \) be a bounded domain in \( \mathbb{R}^d \), \( d \in \mathbb{N} \), and let \( u \) be a real-valued stochastic process solution of the equation formally written as

\[
(1.1) \quad \frac{\partial u(x,t)}{\partial t} - \int_0^t b(t-s)\Delta u(x,s) \, ds = \dot{\xi}(x,t), \quad (x,t) \in \mathcal{D} \times (0,T],
\]

together with the initial condition \( u(x,0) = u_0(x) \), \( x \in \mathcal{D} \), and boundary condition \( u|_{\partial \mathcal{D}} = 0 \). Here, \( \dot{\xi} \) is a zero mean real-valued Gaussian noise and the time kernel \( b \) is assumed to be real-valued and of positive type; i.e., that for any \( T > 0 \), the kernel \( b \) belongs to \( L^1(0,T) \) and for any continuous function \( f \) on \( [0,T] \) the following

\[\text{License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use}\]
more precisely, let
\[ b(t) = t^{\beta - 1}/\Gamma(\beta), \quad 0 < \beta < 1, \]
the homogeneous deterministic equation has a smoothing property which corresponds to the inequality
\[ \|u^{(m)}(t)\|_{H^{2r}(\mathbb{R})} \leq C t^{-(\beta + 1)r - m} \|u_0\|_{L^2(D)}, \]
where \(|r| \leq 1\) if \(m \geq 1\) and where \(0 \leq r \leq 1\) if \(m = 0\), but with no further smoothing in the spacial variables (see e.g. [13, Theorem 5.5]). The framework of this paper allows for slightly more general kernels but with similar smoothing effects and, in particular, they are of positive type. Hence, together with the positivity of the operator \(-\Delta\), the deterministic equation will remain parabolic in character.

Next we introduce an abstract framework to describe the noise and equation (1.1) more precisely. Let \(Q\) be a self-adjoint, nonnegative linear operator on \(H := L^2(D)\) and \(W^Q\) a Wiener process in \(H\) with covariance operator \(Q\) (or, simply, \(Q\)-Wiener process). We set \(A = -\Delta, D(A) = H^2(D) \cap H^1_0(D)\) and \(H = L^2(D)\). Then \(A\) can be seen as an unbounded linear operator on \(H\) with domain \(D(A)\). For \(b\) given in (1.3) and under reasonable assumptions on \(\partial D\), our main assumption concerning \(Q\) in (1.1) is that \(A^\kappa Q\) defines a bounded operator on \(L^2(D)\) with \(d/2 - 1/(\beta + 1) < \kappa < d/2\).

If we write \(u(t) = u(\cdot, t)\), considered as an \(H\)-valued stochastic process, then (1.1) can be rewritten in the abstract Itô form as
\[ du(t) = b(t)Au(s)ds + dW^Q(t), \quad t \in (0,T], \]
with initial condition \(u(0) = u_0 \in H\).

While the literature on numerical methods for deterministic infinite dimensional Volterra equations is abundant (see, for example, [16,12,13,20], which is a very incomplete list), the numerical analysis of stochastic Volterra equations is completely missing. We are only aware of [7] where an algorithm is described and numerical experiments are performed with no error analysis given. We will consider a numerical approximation of (1.3) by means of an Euler scheme and a Laplace transform convolution quadrature in time together with a finite element method in space. Let \(n \geq 1\) be an integer, \(\Delta t = T/n\) and \(t_k = k \Delta t, k = 0, \ldots, n\). Also, let \(\{V_h\}_{h>0}\) be a family of finite dimensional subspaces of \(D(A^{1/2}) = H^1_0(D)\). For each \(1 \leq k \leq n\), we look for an approximation of \(u(t_k)\) in \(V_h\) by \(u_{k,h}\) defined by the following induction:

\[ (u_{k,h} - u_{k-1,h}, v_h) + \Delta t \sum_{j=1}^k \omega_{k-j}(Au_{j,h}, v_h) = \sqrt{\Delta t}(Q^{1/2} \varsigma_k, v_h), \quad k \geq 1, \]
for any \(v_h \in V_h\), where \(\sqrt{\Delta t} \varsigma_k\) is the noise increment and where \((\cdot, \cdot)\) is the inner product of \(H\). The approximation of the convolution term in (1.3) is achieved via
a quadrature rule such that for any continuous function \( f \) on \([0,T]\),

\[
\sum_{j=1}^{k} \omega_{k-j} f(t_j) \sim \int_0^{t_k} b(t_k - s) f(s) \, ds = (b \ast f)(t_k).
\]

Then, the approximation of \( b \ast f \) on the time grid \( t_k, k = 0, \ldots, n \), is obtained from a discrete convolution with the values of \( f \) on the same grid. Before going into detail, let us point out that not just any quadrature rule can be chosen. In particular, it will be important for the chosen quadrature to satisfy a discrete analogue of (1.2).

In order to understand the specific quadrature rule used in this paper, we will take the example of the Riesz kernel (1.3). Let us note that in this case the Laplace transform of \( b \) is \( z^{-\beta} \) and the term \( b \ast \Delta u \) in (1.1) can be seen as the fractional integral \((\partial/\partial t)^{-\beta}(\Delta u)\). Then, the idea is to use the same Euler approximation of \( \partial/\partial t \) in both terms on the left-hand side of (1.1). Since the discrete Laplace transform of the implicit Euler scheme is \((1 - z)/\Delta t\), one chooses the quadrature weights to have discrete Laplace transform \(((1 - z)/\Delta t)^{-\beta}\).

Such a convolution quadrature has been introduced in [9,10]. It was motivated by the fact that the main properties of the solution of the homogeneous problem, like stability, existence, or regularity, are largely determined by the distribution of the frequencies of the kernel (by means of its Fourier or Laplace transform), especially when the kernel has weak singularities or when it exhibits different behaviour at different time scales. Since, by construction, the discrete Laplace transform of the quadrature kernel is closely related to the Laplace transform of the continuous kernel, it is thus possible to carry over frequency domain conditions from the continuous problem to the discretization and thereby obtain stable approximations. Moreover, this kind of quadrature rule inherits the rate of approximation from the time integrator of \( \partial/\partial t \). In the context of stochastic PDEs, we think that it is important to make sure that the deterministic part of the scheme is stable and that the perturbations are due to the noise only.

Although the analysis in the present paper allows for kernels slightly more general than (1.3), we follow the same idea: the convolution quadrature weights \( \{\omega_k\} \) in (1.6) will be defined by means of the Laplace transform of the kernel \( b \). Therefore, we choose the quadrature coefficients to have generating function \( \hat{b}((1 - z)/\Delta t) \), where \( \hat{b} \) denotes the Laplace transform of \( b \); that is,

\[
\sum_{n=0}^{+\infty} \omega_k z^k = \hat{b} \left( \frac{1 - z}{\Delta t} \right), \quad |z| < 1.
\]

We will not focus here on practical algorithms for the computations of the quadrature weights and we refer the reader, for example, to [10].

While precise conditions on the kernel \( b \) are postponed to Sections 2 and 4, we can already state our main result, Theorem 5.1, with the above notations in the case of the specific kernel (1.3) when \( D \) is a convex polygonal domain using continuous, piecewise linear finite elements. We shall prove a (strong) error estimate of the form

\[
\left( E(\|u_{n,h} - u(T)\|) \right)^{1/2} \leq C(\Delta t^\gamma + h^\nu),
\]

where \( \gamma < (1 - (\beta + 1)(d/2 - \kappa))/2 \) and \( \nu < 1/(\beta + 1) - d/2 + \kappa \). Let us note that we recover the known order of convergence for the heat equation (see [8,16,21]) when \( \beta \to 0 \).
The paper is organized as follows. In Section 2 we introduce notation, recall some basic preliminary results, and state our main assumptions on $A$, $Q$ and $b$. We note that assumptions (2.8)–(2.9) on $A$ and $Q$ could be replaced by a single, somewhat sharper, assumption as discussed in Remarks 2.5 and 5.2. It is, however, harder to check in most cases. In Section 3 we study the space semidiscretization of (1.1) and strong error estimates are derived for smooth initial data under minimal regularity assumptions (Assumption 1) on (1.1) and sharp error estimates are derived for nonsmooth initial data. One of the regularity assumptions (Assumption 1) on (1.1) and strong error estimates are derived for smooth initial data under minimal restriction on $b$. In Section 4 we prove strong error estimates for the time semidiscrete scheme with nonsmooth initial data. One of the key results in this direction is Theorem 4.1, where we prove a general $l^p$-stability result on Lubich's convolution quadrature based on the Backward Euler method for deterministic Volterra equations. Interestingly, this stability result implies (Corollary 4.2) that the time-discrete scheme exhibits the same smoothing effect in time as the solution under Assumption 1 on $b$. However, in order to obtain optimal convergence rates for the stochastic problem we need to put a further regularity restriction on $b$ in Subsection 4.2. Assumption 2 which is in fact common in the deterministic literature for nonsmooth initial data. Indeed, Assumption 2 implies that the deterministic equation has an analytic resolvent family while Assumption 1 only implies that the deterministic equation is parabolic. Unlike for equations with no memory term, these two notions are not equivalent (see Chapter 1, Section 3). As far as we know the derivation of nonsmooth initial data estimates using only parabolicity (Assumption 1) remains an open problem. Finally, in the last section, we gather the results from the preceding sections and consider the fully discrete scheme.

2. Notations and preliminaries

Let $(X, \| \cdot \|_X)$ and $(Y, \| \cdot \|_Y)$ be two Banach spaces and let $\mathcal{B}(X,Y)$ denote the space of bounded linear operators from $X$ into $Y$ endowed with the norm $\|B\|_{\mathcal{B}(X,Y)} = \sup_{x \in X} \|Bx\|_Y/\|x\|_X$. When $X = Y$, we use the shorter notation $\mathcal{B}(X)$ for $\mathcal{B}(X,X)$. If $X$ is a Banach space and $I$ is an interval in $\mathbb{R}$ then, $L^p(I, X), 1 \leq p < \infty$, denotes the space of functions $f : I \to X$ which are measurable and $t \to \|f(t)\|^p$ is integrable on $I$, equipped with the usual norm. If $p = \infty$, then $L^\infty(I, X)$ denotes the space of functions $f : I \to X$ which are measurable and $t \to \|f(t)\|$ is essentially bounded on $I$ endowed with the usual norm.

Throughout this paper, $H$ denotes a real separable Hilbert space with inner product $(\cdot, \cdot)$ and associated norm $\| \cdot \|$. We consider the stochastic Volterra equation given in the abstract Itô form as

$$du + \left( \int_0^t b(t-s)Au(s) \, ds \right) \, dt = dW^\omega, \quad t \in (0, T]; \quad u(0) = u_0 \in H,$$

where the process $\{u(t)\}_{t \in [0,T]}$ is an $H$-valued stochastic process, $A$ is a densely defined, nonnegative self-adjoint unbounded operator on $H$ with compact inverse, and $W^\omega$ is a $Q$-Wiener process in $H$ on a given probability space $(\Omega, \mathcal{F}, \mathbb{P})$. The weak solution of (2.1) is a mean-square continuous $H$-valued process satisfying

$$(u(t), \eta) + \int_0^t \int_0^r b(r-s) \, (u(s), A^* \eta) \, ds \, dr = (u_0, \eta) + \int_0^t (\eta, dW^Q(s)),$$

for all $\eta \in D(A^*)$ almost surely for all $t \in [0, T]$.

It is well known that such assumptions on $A$ imply the existence of a sequence of nondecreasing positive real numbers $\{\lambda_k\}_{k \geq 1}$ and an orthonormal basis $\{e_k\}_{k \geq 1}$
of $H$ such that

$$Ae_k = \lambda_k e_k, \quad \lim_{k \to +\infty} \lambda_k = +\infty. \quad (2.2)$$

We define classically, by means of the spectral decomposition of $A$, the domains $D(A^s)$ of fractional powers $s \in \mathbb{R}$ of $A$ and we set

$$\|v\|_s = \|A^{s/2}v\|, \quad v \in D(A^{s/2}).$$

**Remark 2.1.** We note that since $A$ is nonnegative self-adjoint, $-A$ generates an analytic contraction semigroup on $H$. Moreover, for any $\theta < \pi$, there exists $M_\theta \geq 1$ such that the following holds:

$$\|(zI + A)^{-1}\|_{\mathcal{B}(H)} \leq \frac{M_\theta}{|z|}, \quad \text{for any } z \in \Sigma_\theta,$$

where $\Sigma_\theta = \{z \in \mathbb{C} \setminus \{0\}, |\arg(z)| < \theta\}$.

Let $\mathcal{L}_1(H)$ denote the set of nuclear operators from $H$ to $H$; that is, $T \in \mathcal{L}_1(H)$ if there are sequences $\{a_j\}, \{b_j\} \subset H$ with $\sum_{j=1}^{\infty} \|a_j\| \|b_j\| < \infty$ and such that

$$Tx = \sum_{j=1}^{\infty} (x, b_j)a_j, \quad x \in H.$$ 

Sometimes these operators are referred to as trace class operators. For $T \in \mathcal{L}_1(H)$ we define $\text{Tr}(T)$, the trace of $T$, by

$$\text{Tr}(T) = \sum_{n=1}^{+\infty} (Be_n, e_n),$$

where $\{e_n\}$ is an orthonormal basis of $H$. This definition turns out to be independent of the choice basis. Furthermore, if $L \in \mathcal{L}_1(H)$ and $M \in \mathcal{B}(H)$, then $LM, ML \in \mathcal{L}_1(H)$ and

$$\text{Tr}(LM) = \text{Tr}(ML). \quad (2.3)$$

If $L$ is also symmetric and nonnegative, then

$$\text{Tr}(LM) \leq \text{Tr}(L)\|M\|_{\mathcal{B}(H)}. \quad (2.4)$$

Hilbert-Schmidt operators also play an important role in this paper. An operator $L \in \mathcal{B}(H)$ is Hilbert-Schmidt if $L^*L \in \mathcal{L}_1(H)$ or, equivalently, $LL^* \in \mathcal{L}_1(H)$. We denote by $\mathcal{L}_2(H)$ the space of such operators. It is a Hilbert space under the norm

$$\|L\|_{\mathcal{L}_2(H)} = (\text{Tr}(L^*L))^{1/2} = (\text{Tr}(LL^*))^{1/2}. \quad (2.5)$$

Our analysis will also use the Laplace transform. Let $f : \mathbb{R}_+ \to H$ be subexponential; i.e., that for any $\varepsilon > 0$ the function $t \mapsto f(t)e^{-\varepsilon t}$ belongs to $L^1(\mathbb{R}_+, H)$. We define the Laplace transform of $f : \mathbb{C}_+ \to H$ by

$$\hat{f}(z) = \int_0^{+\infty} f(t)e^{-zt} dt, \quad \text{Re } z > 0,$$

where we have used the same notation $H$ for the complexification of $H$. We denote by $\ast$ the Laplace convolution product on $[0, t]$ of two locally integrable subexponential functions $f, g \in L^1_{loc}(\mathbb{R}_+, H)$ defined as

$$(f \ast g)(t) = \int_0^t f(t - s)g(s) \, ds.$$
It is well known that $f \ast g \in L_{loc}^1([\mathbb{R}_+, H)$ is subexponential and
$$\hat{f} \ast \hat{g}(z) = \hat{f}(z) \hat{g}(z), \quad \text{Re } z > 0.$$

2.1. Main assumptions. Next we state the main assumptions concerning the kernel $b$ and the operators $A$ and $Q$, which will be used throughout this paper.

Regarding $b$, first note that property (1.2) can be characterized by means of the Laplace transform $\hat{b}$ of $b$. It is equivalent to say that $\text{Re}(\hat{b}(\lambda)) \geq 0$ for any $\text{Re } \lambda > 0$ (see [15] or [17, page 38]). Now it is clear that the positivity property (1.2) is not sufficient, in general, to ensure smoothing effects like (1.4) when working with kernels that are more general than (1.3). This is why, following [3] and [14], we will impose stronger conditions on $b$.

Assumption 1. The kernel $0 \neq b \in L_{loc}^1(\mathbb{R}_+)$, is 3-monotone; that is, $b, -\dot{b}$ are nonnegative, nonincreasing, convex, and $\lim_{t \to \infty} b(t) = 0$. Furthermore,

$$(2.6) \quad \rho := 1 + \frac{2}{\pi} \sup \{|\arg \hat{b}(\lambda)|, \text{Re } \lambda > 0\} \in (1, 2).$$

In the special case of the Riesz kernel given in (1.3) one can easily show that $\rho = 1 + \beta$. From now on we set $\beta = \rho - 1$ with $\rho$ defined by (2.6).

Remark 2.2. It follows from [17, Proposition 3.10] that for 3-monotone and locally integrable kernels $b$, condition (2.6) is equivalent to

$$(2.7) \quad \lim_{t \to 0} \frac{1}{t} \int_0^t sb(s) \, ds \int_0^t -sb(s) \, ds < +\infty.$$ 

Also note that, by (2.6), we have that $\text{Re}(\hat{b}(\lambda)) \geq 0$ for $\text{Re } \lambda > 0$ and hence $b$ satisfies (1.2).

For $A$ and $Q$ we suppose that there exists numbers $\alpha > 0$ and $\kappa \in \mathbb{R}$ such that

$$(2.8) \quad \text{Tr}(A^{-\alpha}) < +\infty,$$

$$(2.9) \quad A^\kappa Q \in \mathcal{B}(H), \quad \alpha - \frac{1}{\rho} < \kappa \leq \alpha.$$ 

2.2. The nonhomogeneous deterministic problem. Given $f \in L^1([0, T]; H)$, Assumption 1 together with the fact that $A$ is positive and self-adjoint implies that the deterministic problem,

$$(2.10) \quad \dot{u}(t) + \int_0^t b(t-s)Au(s) \, ds = f(t), \quad t \in (0, T], \quad u(0) = u_0 \in H,$$

is well posed for all $T > 0$. Indeed, there exists a resolvent family $\{S(t)\}_{t \geq 0} \subset \mathcal{B}(H)$ which is strongly continuous for $t \geq 0$, differentiable for $t > 0$ and uniformly bounded by 1; see [17, Corollary 1.2 and Corollary 3.3]. The unique mild solution of (2.10) is given by the following variation of parameter formula [17, Proposition 1.2]

$$u(t) = S(t)u_0 + \int_0^t S(t-s)f(s) \, ds, \quad t \in [0, T].$$

Remark 2.3. The positivity of the kernel $b$ defined in (1.2), together with the positivity of the operator $A$ already allows for the construction of a unique solution to (2.10) using an energy argument; see [17, Corollary 1.2]. Assumption 1 gives further integrability and smoothing properties for $\{S(t)\}_{t \geq 0}$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Note that such a resolvent family does not satisfy the semi-group property because of the nonlocal feature of the memory term in (2.10). Nevertheless, it can be written explicitly using the spectral decomposition (2.2) of $A$ as

\begin{equation}
S(t)v = \sum_{k=1}^{+\infty} s_k(t)(v, e_k)e_k,
\end{equation}

where the functions $s_k(t)$ are the solutions of the ordinary differential equations

\begin{equation}
\dot{s}_k(t) + \lambda_k \int_0^t b(t-s)s_k(s) \, ds = 0, \quad s_k(0) = 1.
\end{equation}

The next proposition summarizes the main properties of the functions $\{s_k\}_{k \geq 1}$.

**Proposition 2.4.** Suppose that $b$ satisfies Assumption 1 and let $\rho \in (1, 2)$ as defined in (2.6). Then $\lim_{r \to \infty} s_k(r) = 0$ for all $k \geq 1$ and there exists $C_0 > 0$ such that for any $k \geq 1$,

\begin{align*}
&\|s_k\|_{L^\infty(\mathbb{R}_+)} \leq 1, \\
&\|s_k\|_{L^1(\mathbb{R}_+)} \leq C_0,
\end{align*}

\begin{align*}
&\|ts_k\|_{L^1(\mathbb{R}_+)} \leq C_0 \lambda_k^{-1/\rho}, \\
&\|s_k\|_{L^1(\mathbb{R}_+)} \leq C_0 \lambda_k^{-1/\rho}.
\end{align*}

**Proof.** Estimate (2.13) follows from [17, Corollary 1.2], inequalities (2.14) and (2.15) can be found in [14, Proposition 6] and estimate (2.16) is shown in [3, Lemma 3.1] where also the fact $\lim_{r \to \infty} s_k(r) = 0$ for all $k \geq 1$ is shown in the proof of the lemma. \qed

Smoothing effects of the resolvent family $\{S(t)\}_{t \geq 0}$ when $b$ satisfies Assumption 1 can be now easily proved using Proposition 2.4.

**Proposition 2.5.** Let $b$ and $\rho$ be as in Proposition 2.4. Then for any $t > 0$, there exist constants $C_0, C_1 > 0$ such that for any $0 \leq s \leq 2/\rho$ and $0 \leq s' \leq 2$,

\begin{align*}
&\|A^{s/2} S(t)\|_{\mathcal{B}(H)} \leq C_0 t^{-s\rho/2}, \quad t > 0, \\
&\|A^{-s'/2} \dot{S}(t)\|_{\mathcal{B}(H)} \leq C_1 \|b\|_{L^1(0, t)}^{s'/2} t^{s'/2 - 1}, \quad t > 0.
\end{align*}

**Proof.** For any $\delta \in (0, 1)$ and any $k \geq 1$, H"{o}lder’s inequality, (2.14) and (2.15) yields

\begin{align*}
\int_0^{+\infty} u^\delta |\dot{s}_k(u)| \, du &= \int_0^{+\infty} u^\delta |\dot{s}_k(u)|^\delta |s_k(u)|^{1-\delta} \, du \\
&\leq \left( \int_0^{+\infty} u |s_k(u)| \, du \right)^\delta \left( \int_0^{+\infty} |s_k(u)| \, du \right)^{1-\delta} \\
&\leq C_0 \lambda_k^{-\delta/\rho}.
\end{align*}

Note, that the previous final estimate also holds for $\delta = 0, 1$ by (2.14) and (2.15). Then, since $s_k(t) = -\int_t^{+\infty} u^{-\delta} u^\delta s_k(u) \, du$ as $\lim_{r \to \infty} s_k(r) = 0$ for all $k \geq 1$ by Proposition 2.4 we can conclude that

\begin{equation}
|s_k(t)| \leq C_0 t^{-\delta} \lambda_k^{-\delta/\rho}, \quad t > 0, \quad \delta \in [0, 1].
\end{equation}
Thus, for any $s \in [0, 2/\rho]$ and $x \in H$, (2.19) with $0 \leq \delta = \rho s/2 \leq 1$ implies

$$
\|A^{s/2} S(t)x\|^2 = \sum_{k \geq 1} \lambda_k^s s_k(t)^2(x, e_k)^2 \leq C_0 t^{-\rho s/2}\|x\|^2,
$$

which is (2.17). To show (2.18), we use [17, Corollary 3.3] which states that under Assumption 1 and since 0 belongs to the resolvent set of $A$, there is $M > 0$ such that

$$
\|\dot{S}(t)x\| \leq Mt^{-1}\|x\|, \quad x \in H, \quad t > 0.
$$

On the other hand, we can bound $\dot{S}(t)x$ for $x \in D(A)$ as follows:

$$
\|\dot{S}(t)x\|^2 = \sum_{k \geq 1} (\dot{s}_k(t))^2(x, e_k)^2
$$

$$
= \sum_{k \geq 1} \lambda_k^2 \left( \int_0^t (b(t-s)s_k(s))ds \right)^2(x, e_k)^2 \leq \|b\|^2_{L^1(0,t)}\|Ax\|^2,
$$

where we have used (2.12) and (2.13). Finally, interpolation between (2.20) and (2.21) yields (2.18).

**Remark 2.6.** The estimate in (2.18) does not provide an optimal rate, in fact, it is the worst case scenario, as further smoothing may come from $\|b\|_{L^1(0,t)}$. The rate can be improved if we impose further regularity assumptions on $b$. Indeed, if in addition, $b$ satisfies Assumption 2 from Subsection 4.2, then by (4.3) and (4.8) it follows that $\dot{b}(\lambda) \sim \lambda^{1-\rho}$ as $\lambda \to \infty$. Thus, the nonnegativity of $b$ implies that $\|b\|_{L^1(0,t)} \leq Ct^{1-\rho}$ by a Tauberian theorem for the Laplace transform (see, for example, [22, Chapter V, Theorem 4.3]). Therefore, in this case, we get a sharper estimate

$$
\|A^{-s'/2}\dot{S}(t)\|_{B(H)} \leq C_1 t^{\rho s'/2-1}, \quad t > 0, \quad 0 \leq s' \leq 2.
$$

Nevertheless, the rate given in (2.18) is sufficient for our needs when it is used in the deterministic error analysis for smooth initial data.

2.3. **The continuous stochastic problem.** Next we recall an existence result for the problem (2.1) and, for the sake of completeness, we indicate a proof (see [3, Theorem 2.1] and we refer to [18] for more general noise).

**Proposition 2.7.** Let $A$ and $Q$ satisfy (2.8)–(2.9) and let $b$ satisfy Assumption 1. Then there exists a unique $H$-valued (Gaussian) weak solution $u$ of (2.1) given by the variation of constants formula

$$
u(t) = S(t)u_0 + \int_0^t S(t-s)dW^Q(s).
$$

Furthermore, the stochastic convolution term has a version whose trajectories are a.s. $\theta$-Hölder continuous for any $\theta < (1 - \rho(\alpha - \kappa))/2$. 

Proof. Analogously to [4, Theorem 5.4], it is sufficient to show that the stochastic convolution is well defined. By Itô’s isometry,

\[
\mathbb{E} \left\| \int_0^t S(t-s) \, dW^Q(s) \right\|^2 = \int_0^t \|S(t-s)Q^{1/2}\|^2_{L_2(H)} \, ds
\]

\[
= \int_0^t \sum_{i \geq 1} \|S(t-s)Q^{1/2}e_i\|^2 \, ds
\]

\[
= \int_0^t \sum_{i,j \geq 1} (S(t-s)Q^{1/2}e_i,e_j)^2 \, ds
\]

\[
\leq C_0 \sum_{j \geq 1} \sum_{i \geq 1} \lambda_j^{-1/p}(Q^{1/2}e_i,e_j)^2
\]

\[
= C_0 \|A^{-1/(2p)}Q^{1/2}\|^2_{L_2(H)},
\]

where we have used Parseval’s identity, (2.13) and (2.16). By (2.9) we have that 
\[-1/p - \kappa < -\alpha,\]

and thus also using (2.4),

\[
\|A^{-1/(2p)}Q^{1/2}\|^2_{L_2(H)} = \text{Tr}(A^{-1/p}Q) = \text{Tr}(A^{-1/p-\kappa}A^{\kappa}Q)
\]

\[
\leq \text{Tr}(A^{-1/p-\kappa})\|A^{\kappa}Q\|^2_{B(H)} \leq \text{Tr}(A^{-\alpha})\|A^{\kappa}Q\|^2_{B(H)}.
\]

Finally, the proof of the Hölder regularity in time of \(u\) uses similar techniques and is omitted. \(\square\)

Remark 2.8. Note that assumptions (2.8)–(2.9) are stronger than the minimal assumption \(\|A^{-1/(2p)}Q^{1/2}\|^2_{L_2(H)} < +\infty\) needed for the existence of a mean squared continuous solution. One can replace (2.8)–(2.9) by

\[
\|A^{(s-1/p)/2}Q^{1/2}\|^2_{L_2(H)} < +\infty
\]

for some \(s > 0\) as a single main assumption on \(A\) and \(Q\) and obtain Hölder regularity of order less than \(\min(\frac{1}{2}, \frac{\rho s}{2})\).

3. Space discretization

In this section we discretize (2.1) in space by a standard piecewise continuous finite element method. We refer to the monograph [19] for further details on finite elements. We shall derive strong error estimates for the spatially semidiscrete problem for smooth initial data only imposing Assumption 1 on \(b\). We will see later that for time discretization and also for the fully discrete scheme, we have to put further restrictions on \(b\). Let \(\{T_h\}_{0 < h < 1}\) denote a family of triangulations of \(D\), with mesh size \(h > 0\) and consider finite element spaces \(\{V_h\}_{0 < h < 1}\), where \(V_h \subset H^1_0(D)\) consists of continuous piecewise linear functions vanishing at the boundary of \(D\). In order to derive the finite element formulation we look for a \(V_h\)-valued process \(u_h\) such that

\[
\begin{cases}
(du_h(t), \chi) + \int_0^t b(t-s)(\nabla u_h(t), \nabla \chi) \, ds \, dt = (dW^Q(t), \chi), \quad \chi \in V_h, \quad t > 0, \\
u_h(0), \chi) = (u_0, \chi).
\end{cases}
\]
We introduce the “discrete Laplacian”
\begin{equation}
A_h : V_h \rightarrow V_h, \quad (A_h \psi, \chi) = (\nabla \psi, \nabla \chi), \quad \psi, \chi \in V_h,
\end{equation}
and the orthogonal projector
\[ P_h : H \rightarrow V_h, \quad (P_h f, \chi) = (f, \chi), \quad \chi \in V_h. \]

It is clear that the operator \( A_h \) is a positive definite bounded operator on \( V_h \). Let us note also that using the definition (3.1) of \( A_h \), the following uniform inequality can be easily derived:
\begin{equation}
\| A_h^{-1/2} P_h x \| \leq \| A^{-1/2} x \|, \quad x \in H.
\end{equation}
Then, using the \( L_2 \)-stability of \( P_h \) and some interpolation theory, we also have that
\begin{equation}
\| A_h^{-\delta} P_h x \| \leq \| A^{-\delta} x \|, \quad \delta \in [0, \frac{1}{2}], \quad x \in H.
\end{equation}

Similarly to \(-A\), the operator \(-A_h\) generates an analytic contraction semigroup on \( V_h \) and satisfies the uniform resolvent estimate
\[ \| z (z + A_h)^{-1} P_h \| = \| z R(z, A_h) P_h \| \leq M_{\phi}, \]
for \( z \in \Sigma_{\phi} = \{ z \in \mathbb{C} : |\arg(z)| < \phi < \pi \} \). Since \( A_h R(z, A_h) = I - z R(z, A_h) \), it follows that
\begin{equation}
\| A_h R(z, A_h) P_h \|_{B(H)} \leq M_{\phi} + 1, \quad z \in \Sigma_{\phi}.
\end{equation}

Then we can rewrite the spatially semidiscrete problem in the same form as the original one as
\begin{equation}
\begin{cases}
\text{du} + \left( t - s \right) A_h u_h(s) \, ds = P_h \, dW^Q(t), \quad t > 0, \\
\end{cases}
\end{equation}

Similarly to the original problem the weak solution is given by
\[ u_h(t) = S_h(t) P_h u_0 + \int_0^t S_h(t - s) P_h \, dW^Q(s), \]
where the resolvent family \( \{ S_h(t) \}_{t \geq 0} \) can be written explicitly as
\[ S_h(t) P_h u_0 = \sum_{k=1}^{\infty} s_{h,k}(t) (u_0, e_{h,k}) e_{h,k}. \]

Here \( (\lambda_{h,k}, e_{h,k}) \) are the eigenpairs of \( A_h \) and \( s_{h,k}(t) \) are the solution of the ODEs
\[ s_{h,k}(t) + \lambda_{h,k} \int_0^t b(t - s) s_{h,k}(s) \, ds = 0, \quad s_{h,k}(0) = 1. \]

We have the following stability result.

**Lemma 3.1.** If \( b \) satisfies Assumption \([1]\) then for some \( C > 0 \),
\[ \int_0^t \| S(s)x \|^2 \, ds \leq C \| x \|^2 \bigg|_{\frac{1}{h}}, \quad t > 0 \]
and
\[ \int_0^t \| S_h(s) P_h x \|^2 \, ds \leq C \| x \|^2 \bigg|_{\frac{1}{h}}, \quad t > 0, \quad h > 0. \]
Proof. We have, by (2.13) and (2.16), that
\[ \int_0^t \| S(s)x \|^2 \, ds = \sum_{k=1}^{\infty} \int_0^t s_k^2(s) \, ds \, (x, e_k)^2 \]
\[ \leq \sum_{k=1}^{\infty} \| s_k \|_{L^{\infty}(R_+)} \| s_k \|_{L^1(R_+)} (x, e_k)^2 \leq C_0 \sum_{k=1}^{\infty} \lambda_k^{-1/\rho} (x, e_k)^2 = C_0 \| x \|_{1/\rho}. \]
As the constants in (2.13) and (2.16) do not depend on \( \lambda_k \), we similarly obtain
\[ \int_0^t \| S_h(s)P_hx \|^2 \, ds \leq C_0 \| A_h^{-1/2\rho} P_hx \|^2. \]
Finally, since \(-1/2 < -1/2\rho < -1/4\), using (3.3) with \( \delta = 1/(2\rho) \), completes the proof. \( \square \)

The error analysis is based on the Ritz projection
\[ R_h : H^1_0(D) \rightarrow V_h. \quad (\nabla R_h v, \nabla \chi) = (\nabla v, \nabla \chi), \quad v \in H^1_0(D), \quad \chi \in V_h. \]
In particular, we assume that \( R_h \) satisfies the error bound
\[ (3.6) \quad \| R_h v - v \| \leq C h^\gamma \| v \|_{\gamma}, \quad v \in D(A^{\gamma/2}), \quad 1 \leq \gamma \leq 2. \]
This puts some restriction on the domain \( D \) but it is satisfied for convex polygonal domains, for instance.

Next we prove an \( L^2((0, \infty), H) \) error estimate for the space semidiscretization of the deterministic problem. It is an extension of the result in \( \text{[2]} \) where the special kernel \( b(t) = \frac{1}{(\pi t)^{\beta}} e^{-t/t^{\beta-1}} \) was considered.

**Proposition 3.2.** If \( b \) satisfies Assumption \( \text{H} \) and (3.6) holds, then
\[ \int_0^\infty \| S(t)x - S_h(t)P_hx \|^2 \, dt \leq C h^{2\delta} \| x \|_{s-\delta}, \quad 0 \leq s \leq 2. \]

**Proof.** It follows from Lemma 3.1 that
\[ (3.7) \quad \int_0^t \| (S(s) - S_h(s)P_hx) \|^2 \, ds \leq 2 \int_0^t \| S(s)x \|^2 + \| S_h(s)P_hx \|^2 \, ds \leq C \| x \|_{s-\delta}. \]
To prove an error estimate of optimal order we set
\[ e(t) := S(t)x - S_h(t)P_hx := v(t) - v_h(t) = v(t) - P_h v(t) + P_h v(t) - v_h(t) := \rho(t) + \theta(t). \]
For \( \rho \), using the best approximation property of \( P_h \), we obtain by Lemma 3.1 and (3.6) that
\[ (3.8) \quad \int_0^\infty \| \rho(t) \|^2 \, dt \leq \int_0^\infty \| (R_h - I)v(t) \|^2 \, dt \leq C h^{4} \| x \|_{2-\delta}. \]
In a standard way one derives an equation for \( \theta \) which reads
\[ \begin{cases} \dot{\theta}(t) + \int_0^t b(t-s)A_h \theta(s) \, ds = A_h P_h \int_0^t b(t-s)(R_h - I)v(s) \, ds, \quad t > 0, \\ \theta(0) = 0. \end{cases} \]
Taking Laplace transforms of both sides yields
\[ z \hat{\theta}(z) + \hat{b}(z)A_h \hat{\theta}(z) = A_h P_h (R_h - I)\hat{v}(z) \hat{b}(z). \]
Therefore,
\begin{equation}
\hat{\theta}(z) = A_h R \left( \frac{z}{b(z)} \right) A_h P_h (R_h - I) \hat{v}(z).
\end{equation}

It can be shown that \( \hat{b} \) extends continuously to \( i\mathbb{R} \setminus \{0\} \); see, for example, [14]. Therefore, using (2.6), it follows that \( \frac{ik}{b(ik)} \in \Sigma_\phi, \ k \in \mathbb{R} \setminus \{0\} \), with \( \phi < \pi \). Thus, \( \|A_h R \left( \frac{ik}{b(ik)} \right) A_h P_h \|_{\mathcal{B}(H)} \leq (M_\phi + 1) \) by (3.4). Therefore, setting \( z = ik, \ k \in \mathbb{R} \setminus \{0\} \), in (3.9) and using the isometry property of the Fourier transform we obtain, by Lemma 3.21 and (3.6), that
\begin{equation}
\int_0^\infty \|\theta(t)\|^2 \, dt \leq (M_\phi + 1) \int_0^\infty \| (R_h - I) v(t) \|^2 \, dt \leq Ch^4 \|x\|_{2_{-\frac{1}{2}}}^2.
\end{equation}

Interpolation using (3.7), (3.8), and (3.10) yields
\[ \int_0^\infty \|e(t)\|^2 \, dt \leq 2 \int_0^\infty (\|\rho(t)\|^2 + \|\theta(t)\|^2) \, dt \leq Ch^{2s} \|x\|_{s_{\frac{1}{2}}}^2, \quad 0 \leq s \leq 2. \]

Next, using the error analysis from [13], we have the following pointwise smooth data estimate for the spatially semidiscrete scheme.

**Proposition 3.3.** If \( b \) satisfies Assumption 1 and (3.6) holds, then for every \( \epsilon > 0 \) there is \( C = C(T, \epsilon) \) such that
\[ \|S(t)x - S_h(t)P_h x\| \leq Ch^s \|x\|_{s(1+\epsilon)}, \quad 0 \leq s \leq 2, \ t \in [0, T]. \]

**Proof.** As already observed, Assumption 1 implies that \( b \) is a positive definite kernel. Therefore, by [13] Theorem 2.1, it follows that
\[ \|S(t)x - S_h(t)P_h x\| \leq Ch^2 \left( \|x\|_2 + \int_0^t \|\hat{S}(s)x\|_2 \, ds \right). \]

Proposition 2.3 implies that
\begin{equation}
\int_0^t \|\hat{S}(s)x\|_2 \, ds = \int_0^t \|A^{-\epsilon}\hat{S}(s)A^{1+\epsilon}x\| \, ds \leq C(T, \epsilon) \|x\|_{2+2\epsilon}.
\end{equation}

Finally, since \( \|S(t) - S_h(t)P_h\|_{\mathcal{B}(H)} \leq 2 \), interpolation finishes the proof. \( \square \)

**Theorem 3.4.** Let \( A \) and \( Q \) satisfy (2.8)–(2.9) and let \( b \) satisfy Assumption 1. If \( E\|u_0\|^2_{\nu(1+\epsilon)} < \infty \) and (3.6) holds, then there is \( C = C(T, \epsilon, \nu) \) such that
\[ (E\|u(t) - u_h(t)\|^2)_{\nu, t}^{1/2} \leq Ch^\nu, \quad \nu \leq \frac{1}{\rho} - \alpha + \kappa, \ t \in [0, T]. \]

**Proof.** By the variation of constants formula,
\[ u(t) - u_h(t) = S(t)x - S_h(t)x + \int_0^t (S(t-s) - S_h(t-s)P_h) dW^Q(s). \]

Thus,
\[ E\|u(t) - u_h(t)\|^2 \leq 2E\|S(t)x - S_h(t)x\|^2 + 2E \left\| \int_0^t (S(t-s) - S_h(t-s)P_h) dW^Q(s) \right\|^2 := e_1 + e_2. \]

It follows from Proposition 3.3 that
\[ e_1 \leq Ch^{2\nu} E\|u_0\|^2_{\nu(1+\epsilon)}. \]
To bound $e_2$ we use Itô’s isometry and Proposition 3.2 to obtain
\[
e_2 = \mathbb{E} \left| \int_0^t (S(t-s) - S_h(t-s)P_h) dW^Q(s) \right|^2 \\
= \int_0^t \left\| (S(t-s) - S_h(t-s)P_h)Q^{1/2} \right\|^2_{\mathcal{L}_2(H)} ds
\]
(3.12)
\[
\leq Ch^{2\nu}\sum_{k=1}^{\infty} \left\| A^{(\nu-\frac{1}{\rho})/2}Q^{1/2}e_k \right\|^2 = Ch^{2\nu}\left\| A^{(\nu-\frac{1}{\rho})/2}Q^{1/2} \right\|^2_{\mathcal{L}_2(H)} \\
= Ch^{2\nu}\text{Tr}(A^{(\nu-\frac{1}{\rho})}) \leq Ch^{2\nu}\text{Tr}(A^{(\nu-\frac{1}{\rho})/2}) \| A^\alpha Q \|.
\]

\[\square\]

Remark 3.5. In particular, if $Q = I$, then $d = 1$, $\kappa = 0$ and $\alpha > \frac{1}{2}$ whenever $\nu < \frac{1}{\rho} - \frac{1}{2}$. Also, note that it is clear from the proof that instead of \(2.8\)–\(2.9\) we could assume that $\| A^{(\nu-\frac{1}{\rho})/2}Q^{1/2} \|_{\mathcal{L}_2(H)} < \infty$ and get a convergence rate of order $\nu$. Then, for trace class noise; that is, when $\text{Tr}(Q) < \infty$ we can take $\nu = \frac{1}{\rho}$.

We end this section by showing that the above error estimate is optimal in the sense that it corresponds to the spatial regularity of the solution.

**Theorem 3.6.** Let $A$ and $Q$ satisfy \(2.8\)–\(2.9\) and let $\nu = \frac{1}{\rho} - \alpha + \kappa$, or, let $\| A^{(\nu-\frac{1}{\rho})/2}Q^{1/2} \|_{\mathcal{L}_2(H)} < \infty$ for some $\nu \geq 0$. If $b$ satisfies Assumption \(1\) and $\mathbb{E}\|u_0\|^2 < \infty$, then $\mathbb{E}\|u(t)\|^2 \leq C$ for some $C > 0$ for all $t \geq 0$.

Proof. It follows by Itô’s isometry and the fact that $\|S(t)\| \leq 1$ that
\[
\mathbb{E}\|u(t)\|^2 \leq 2\mathbb{E}\|u_0\|^2 + 2\int_0^t \left\| A^{\nu/2}S(s)Q^{1/2} \right\|^2_{\mathcal{L}_2(H)} ds.
\]

Let $(e_k, \lambda_k)$ be the eigenpairs of $A$. Then, by monotone convergence, the self-adjointness of $A$ and $S$, and Proposition \(2.4\) it follows that
\[
\int_0^t \left\| A^{\nu/2}S(s)Q^{1/2} \right\|^2_{\mathcal{L}_2(H)} ds = \sum_{k=1}^{\infty} \int_0^t \left\| A^{\nu/2}S(s)Q^{1/2}e_k \right\|^2 ds \\
= \sum_{j,k=1}^{\infty} \int_0^t \left| (A^{\nu/2}S(s)e_k, e_j) \right|^2 ds = \sum_{j,k=1}^{\infty} \int_0^t \left\| Q^{1/2}e_k, S(s)A^{\nu/2}e_j \right\|^2 ds \\
= \sum_{j,k=1}^{\infty} \left( Q^{1/2}e_k, \lambda_j^{\nu/2}e_j \right)^2 \int_0^t \left| s_j^2(s) \right| ds \\
\leq \sum_{j,k=1}^{\infty} \left( Q^{1/2}e_k, \lambda_j^{\nu/2}e_j \right)^2 \left\| s_j \right\|_{L^\infty(\mathbb{R}_+)} \left\| s_j \right\|_{L^1(\mathbb{R}_+)} \\
\leq C_0 \sum_{j,k=1}^{\infty} \left( Q^{1/2}e_k, \lambda_j^{\nu/2}e_j \right)^2 \lambda_j^{1-1/\rho} = C_0 \sum_{j,k=1}^{\infty} \left( Q^{1/2}e_k, \lambda_j^{\nu/2-1/\rho}e_j \right)^2 \\
= C_0 \left\| A^{(\nu-\frac{1}{\rho})/2}Q^{1/2} \right\|^2_{\mathcal{L}_2(H)} \leq C_0 \text{Tr}(A^{(\nu-\frac{1}{\rho})/2}) \| A^\alpha Q \|_{\mathcal{B}(H)}^2.
\]

\[\square\]
4. Time discretization

Time discretization is achieved via a classical implicit Euler scheme and, concerning the convolution in time, via a quadrature rule based on (1.7). Let $\Delta t > 0$ and we set $t_n = n \Delta t$ for any integer $n \geq 0$. We look for an approximation $u_n$ of $u(t_n)$ defined by the recurrence

$$
(4.1) \quad u_n - u_{n-1} + \Delta t \left( \sum_{k=1}^{n} \omega_{n-k} Au_k \right) = W^Q(t_n) - W^Q(t_{n-1}), \quad n \geq 1,
$$

with initial condition $u_0 = u(0)$. We recall that the coefficients $\{\omega_k\}_{k \geq 0}$ of the quadrature are chosen such that

$$
(4.2) \quad \sum_{k=0}^{+\infty} \omega_k z^k = \frac{\hat{b}(1 - z)}{\Delta t}, \quad |z| < 1.
$$

Let us note that thanks to [14, estimate (3.6)], we have the lower bound for $\omega_0$,

$$
(4.3) \quad \omega_0 = \frac{\hat{b}(1/\Delta t)}{1} \geq c \Delta t^{\mu-1}, \quad \Delta t < 1,
$$

where $\rho \in (1, 2)$ is defined in (2.6).

In the sequel we derive a discrete mild formulation (variation of constants formula) for (4.1). This formulation cannot be made easily explicit as a function of the operators $A, Q$ and the kernel $b$, because of the memory effect in the drift. First consider the deterministic algorithm

$$
(4.4) \quad v_n - v_{n-1} + \Delta t \left( \sum_{k=1}^{n} \omega_{n-k} Av_k \right) = 0, \quad n \geq 1; \quad v_0 = x.
$$

Taking the $z$-transform, using the notation

$$
\hat{V}(z) = \sum_{k=0}^{\infty} v_k z^k \text{ and } \hat{\omega}(z) = \sum_{k=0}^{\infty} \omega_k z^k,
$$

we get

$$
\hat{V}(z) - x - z\hat{V}(z) + \Delta t \hat{\omega}(z) A(\hat{V}(z) - x) = 0.
$$

Thus,

$$
\hat{V}(z) = (I + \Delta t \hat{\omega}(z) A)((1 - z)I + \Delta t \hat{\omega}(z) A)^{-1}x := \hat{B}(z)x,
$$

where

$$
\hat{B}(z)x = \sum_{k=0}^{\infty} B_k x z^k.
$$

This means that $v_k = B_k x$, $k = 0, 1, \ldots$. Note that $B_0 = \hat{B}(0) = I$. For the stochastic equation it will be useful to rewrite $\hat{B}(z)x$ as

$$
(4.5) \quad \hat{B}(z)x = ((1 - z)I + \hat{\omega}(z)\Delta t A)^{-1}(I + \hat{\omega}(z)\Delta t A)x
$$

\begin{align*}
&= ((1 - z)I + \hat{\omega}(z)\Delta t A)^{-1}x + \hat{\omega}(z)\Delta t A((1 - z)I + \hat{\omega}(z)\Delta t A)^{-1}x \\
&= ((1 - z)I + \hat{\omega}(z)\Delta t A)^{-1}x - (1 - z)((1 - z)I + \hat{\omega}(z)\Delta t A)^{-1}x + x \quad (z((1 - z)I + \hat{\omega}(z)\Delta t A)^{-1} + I)x.
\end{align*}
Now, we consider the stochastic case (4.1) which, after taking the \( z \)-transform, rearranging and using the notation \( w_n = W^Q(t_n) - W^Q(t_{n-1}) \) for \( n \geq 1 \), \( w_0 = 0 \), and

\[
\hat{w}(z) = \sum_{k=0}^{\infty} w_k z^n \quad \text{and} \quad \hat{U}(z) = \sum_{k=0}^{\infty} u_k z^k,
\]

reads as

\[
\hat{U}(z) = \hat{B}(z)x + ((1 - z)I + \hat{\omega}(z)\Delta_tA)^{-1}\hat{w}(z)
\]

\[
= \hat{B}(z)x + \frac{\hat{B}(z) - I}{z} \hat{w}(z) = \hat{B}(z)x + \hat{B}(z) \frac{\hat{w}(z)}{z} - \frac{1}{z} \hat{w}(z),
\]

where we also used (4.5) to rewrite the stochastic term in the previous calculation. This yields the discrete variation of constants formula, taking into account that \( w_0 = 0 \) and that \( B_0 = I \),

\[
(4.6) \quad u_n = B_n x + \sum_{k=0}^{n} B_{n-k} w_{k+1} - w_{n+1} = B_n x + \sum_{k=0}^{n-1} B_{n-k} w_{k+1}.
\]

The importance of this formula lies in the fact that it connects the deterministic case to the stochastic case with the deterministic time-discrete solution operators \( B_n \) explicitly appearing in the formula.

4.1. **Deterministic estimates: stability and smoothing.** The next theorem is interesting in its own right. It shows that Lubich’s convolution quadrature based on the backward Euler scheme has a remarkable qualitative property: it preserves the \( L^p \)-norm of the orbits of the solution. The result can be viewed as a generalization of the ones in [6]; in particular, it removes the additional technical frequency condition in [6, Theorem 2]. The proof uses a representation similar to that in [1]. We also note that the statement holds in Banach spaces as well since the proof does not use Hilbert space techniques.

**Theorem 4.1.** If the resolvent family \( \{S(t)\}_{t \geq 0} \) of (2.10) satisfies

\[
S(\cdot)x \in L^p((0, \infty); H)
\]

for some \( 1 \leq p \leq \infty \) and \( x \in H \), then

\[
\Delta t \sum_{k=1}^{n} \|B_k x\|^p \leq \int_{0}^{\infty} \|S(t)x\|^p \, dt, \quad 1 \leq p < \infty
\]

and

\[
\sup_{k \geq 1} \|B_k x\| \leq \|S(\cdot)x\|_{L^\infty(\mathbb{R}_+)}.
\]

**Proof.** The Laplace Transform of \( \{S(t)\}_{t \geq 0} \) is given by

\[
\hat{S}(z) = (zI + \hat{b}(z)A)^{-1}x.
\]

Using (4.2) and (4.5) we see that the z-transform \( \hat{B}x \) of \( \{B_n x\}_n \) is given by

\[
\hat{B}(z) = z \frac{1}{\Delta t} \hat{S}(\frac{1-z}{\Delta t})x + x = x + z \int_{0}^{\infty} S(\Delta ts) e^{-s} e^{zs} \, ds
\]

\[
= x + \sum_{k=1}^{\infty} z^k \int_{0}^{\infty} S(\Delta ts) e^{-s} s^{k-1} \frac{1}{(k-1)!} \, ds.
\]
Therefore, we conclude that $B_0 = I$ and that

\begin{equation}
B_kx = \int_0^\infty S(\Delta ts)x \frac{e^{-s}S^k}{(k-1)!} ds \quad \text{for } k \geq 1.
\end{equation}

Let

$$f_k(s) := \frac{e^{-s}S^k}{(k-1)!}, \quad k \geq 1.$$  

Then $f_k \geq 0$, $\|f_k\|_{L^1(\mathbb{R}_+)} = 1$. Therefore, if $p = \infty$, we immediately obtain from (4.7) that

$$\sup_{k \geq 1} \|B_kx\| \leq \|S(\cdot)x\|_{L^\infty(\mathbb{R}_+)}.$$  

If $1 \leq p < \infty$, then we use Jensen’s inequality in (4.7), and have

$$\Delta t \sum_{k=1}^n \|B_kx\|^p \leq \sum_{k=1}^n \Delta t \int_0^\infty \|S(\Delta ts)x\|^p f_k(s) ds$$

$$= \int_0^\infty \|S(t)x\|^p \sum_{k=1}^n f_k\left(\frac{t}{\Delta t}\right) dt \leq \sup_{t>0} \sum_{k=1}^\infty f_k(t) \int_0^\infty \|S(t)x\|^p dt.$$  

Finally, noticing that $\sum_{n=1}^\infty f_n \equiv 1$, completes the proof. $\square$

Theorem 4.1 has the following important corollary on the smoothing and stability of the time discretization scheme in case $b$ satisfies Assumption 1.

**Corollary 4.2.** If $b$ satisfies Assumption 1, then, for all $x \in H$,

$$\sup_{k \geq 1} \|B_kx\| \leq \|x\| \quad \text{and} \quad \Delta t \sum_{k=1}^n \|B_kx\|^2 \leq C\|x\|^{2 - \frac{2}{p}}, \quad n \geq 1.$$  

**Proof.** The statement follows from Theorem 4.1 together with Lemma 3.1 and the fact that $\|S(t)\| \leq 1$ for $t \geq 0$. $\square$

Finally, we will need a Hölder type estimate on the resolvent family $\{S(t)\}_{t \geq 0}$.

**Lemma 4.3.** If $b$ satisfies Assumption 1 then $C = C(T, \gamma) > 0$ such that

$$\left(\sum_{k=1}^n \int_{t_{k-1}}^{t_k} \|(S(t_n - s) - S(t_n - t_{k-1}))x\|^2 ds\right)^{1/2} \leq C\Delta t^{\gamma}\|x\|_{s - \frac{1}{p}}, \quad n\Delta t = T,$$

for all $\gamma < \frac{\alpha s}{2}$ where $0 < s \leq \frac{1}{p}.$

**Proof.** It follows from (2.17), with $s = \frac{1}{p} - \epsilon$, and Lemma 3.1 that there is a constant $C = C(\epsilon,T)$ such that, for $0 < \epsilon \leq \frac{1}{p}$,

$$\left(\sum_{k=1}^n \int_{t_{k-1}}^{t_k} \|(S(t_n - s) - S(t_n - t_{k-1}))x\|^2 ds\right)^{1/2} \leq C\|x\|_{s - \frac{1}{p}}, \quad n\Delta t = t_n = T.$$
Next, it follows from Proposition 2.4 that

\[
\sum_{k=1}^{n} \int_{t_{k-1}}^{t_k} \| (S(t_n - s) - S(t_n - t_{k-1}))x \|^2 ds
\]

\[= \sum_{i=1}^{\infty} \langle x, e_i \rangle^2 \sum_{k=1}^{n} \int_{t_{k-1}}^{t_k} (s_i(t_n - s) - s_i(t_n - t_{k-1}))^2 ds \]

\[\leq 2 \sum_{i=1}^{\infty} \langle x, e_i \rangle^2 \int_{t_{k-1}}^{t_k} \left| s_i(t_n - s) - s_i(t_n - t_{k-1}) \right| ds \]

\[\leq 2 \sum_{i=1}^{\infty} \langle x, e_i \rangle^2 \int_{t_{k-1}}^{t_k} \int_{t_n-s}^{t_n-t_{k-1}} |\dot{s}_i(t)| dt ds \]

\[\leq 2 \sum_{i=1}^{\infty} \langle x, e_i \rangle^2 \int_{t_{k-1}}^{t_k} \int_{t_n-t_k}^{t_n-t_{k-1}} |\dot{s}_i(t)| dt ds \]

\[\leq 2 \Delta t \|x\|^2 \sup_{i \geq 1} \|\dot{s}_i\|_{L^1(R_+)} \leq C \Delta t \|x\|^2. \]

Finally, interpolation gives the desired result. \(\square\)

4.2. Deterministic estimates: convergence rates. In order to give an error estimate of optimal order with no initial regularity for the time discretization of the deterministic problem we have to impose another assumption on \(b\). This kind of assumption, that is, the existence of an analytic extension of \(\tilde{b}\) to a sector beyond the left half-plane, is fairly standard in the existing deterministic literature (see, for example, \([5, 9, 11, 12]\)), but it clearly represents a major restriction compared to Assumption [1]. We note that this additional assumption is not needed for neither the spatial error estimates with smooth initial data, and hence for the space-semidiscretization of the stochastic equation, nor for the stability results for the time discretization in the previous subsection.

Assumption 2. The Laplace transform \(\tilde{b}\) of \(b\) can be extended to an analytic function in a sector \(\Sigma_\theta\) with \(\theta > \pi/2\) and \(|\tilde{b}^{(k)}(z)| \leq C|z|^{1-\rho-k}, \ k = 0, 1, z \in \Sigma_\theta\).

Note that Assumption 2 implies that

\[
\omega_0 = \tilde{b}(1/\Delta t) \leq C \Delta t^{\rho-1}, \ \Delta t < 1.
\]

An important example of a family of kernels satisfying both Assumptions [1] and [2] is given by \(b(t) = Ct^{\beta-1}e^{-\eta t}, 0 < \beta < 1\) and \(\eta \geq 0\).

Assumptions [1] and [2] allows us to use the following deterministic nonsmooth data estimate [12, Theorem 3.2].

Proposition 4.4. If Assumptions [1] and [2] hold, then there exists \(C = C(\rho) > 0\) such that

\[
\|S(t_n)x - B_n x\| \leq \frac{C}{t_n} \Delta t \|x\|, \ n \geq 1.
\]

Corollary 4.5. If Assumptions [1] and [2] hold, then there exists \(C = C(T, \gamma, \rho)\) such that

\[
\left( \Delta t \sum_{k=0}^{n} \|S(t_k)x - B_k x\|^2 \right)^{1/2} \leq C \Delta t^{\gamma} \|x\|_{s-1/\rho}, \ n \Delta t = T,
\]

for all \(\gamma < \frac{\rho s}{2}\) where \(0 < s \leq \frac{1}{\rho}\).
Proof. It follows from (2.17), with \( s = \frac{1}{\rho} - \epsilon \), and Corollary 4.2 that there is a constant \( C = C(\epsilon, T) \) such that, for \( 0 < \epsilon < \frac{1}{\rho} \),
\[
\left( \Delta t \sum_{k=0}^{n} \| S(t_k)x - B_kx \|^2 \right)^{1/2} \leq C \| x \|_{\epsilon - \frac{1}{\rho}}, \ n \Delta t = T, \ \epsilon > 0,
\]
where we also used the fact that \( B_0 = S(t_0) = I \). Furthermore, since \( \| S(t_k) - B_k \| \leq 2 \) by Corollary 4.2, it follows from (4.9) that
\[
\| S(t_k)x - B_kx \| \leq C \Delta t^{\frac{1}{2}} - \epsilon t_k^{\frac{1}{2}} \| x \|, \ k \geq 1,
\]
and thus, for some \( C = C(\epsilon, T, \rho) \),
\[
\left( \Delta t \sum_{k=0}^{n} \| S(t_k)x - B_kx \|^2 \right)^{1/2} \leq C \Delta t^{\frac{1}{2}} - \epsilon \| x \|.
\]
Interpolation finishes the proof. \qed

4.3. Error estimate for the stochastic equation. We can now state and proof the main result of this section.

**Theorem 4.6.** Let \( A \) and \( Q \) satisfy (2.8)–(2.9) and let \( b \) satisfy Assumptions [1] and [2]. Suppose further that \( \mathbb{E}\| u_0 \|^2 < \infty \). For \( T > 0 \), let \( \{ u(t) \}_{t \in [0, T]} \) be the unique weak solution of (2.1) and let \( u_n \) be the solution of the scheme (4.1) with \( T = n \Delta t \). Then for any \( \gamma < (1 - \rho(\alpha - \kappa)) / 2 \), there is \( C = C(\rho, \mathbb{E}\| u_0 \|^2) > 0 \) and \( K = K(T, \alpha, \gamma, \kappa, \rho) > 0 \) such that
\[
(4.10) \quad (\mathbb{E}\| u(T) - u_n \|^2)^{1/2} \leq C T^{-1} \Delta t + K \Delta t^\gamma, \quad t_n = n \Delta t = T.
\]

**Proof.** If \( e_n = u(T) - u_n = u(t_n) - u_n \), then (2.28) and (4.6) yields
\[
e_n = (S(t_n) - B_n)u_0 + \sum_{k=1}^{n} \left[ \int_{t_{k-1}}^{t_k} (S(t_n - s) - B_{n-k+1}) dW^q(s) \right].
\]
Taking the expectation of the square of the \( H \)-norm of \( e_n \) leads to, by independence and Itô’s isometry,
\[
(4.11) \quad \mathbb{E}\| e_n \|^2 \leq 2(a + b),
\]
where \( a \) denotes the deterministic part of the error
\[
(4.12) \quad a = \mathbb{E}\| (S(t_n) - B_n)u_0 \|^2,
\]
and \( b \) the stochastic part,
\[
b = \sum_{i=1}^{+\infty} \sum_{k=1}^{n} \int_{t_{k-1}}^{t_k} \| (S(t_n - s) - B_{n-k+1})Q^{1/2} e_i \|^2 ds.
\]
Thanks to (4.9), \( a \) can be bounded as
\[
(4.13) \quad a \leq \frac{C}{T_n} \Delta t^2 \mathbb{E}\| u_0 \|^2, \quad n \geq 1.
\]
We use Corollary 4.5 and Lemma 4.3 to bound $b$ as
\begin{align*}
b &\leq 2 \sum_{i=1}^{\infty} \sum_{k=1}^{n} \int_{t_{k-1}}^{t_{k}} \| (S(t_n-s) - S(t_n-t_{k-1}) )Q^{1/2} e_i \|^2 \, ds \\
&\quad + 2 \sum_{i=1}^{\infty} \sum_{k=1}^{n} \int_{t_{k-1}}^{t_{k}} \| (S(t_n-t_{k-1}) - B_{n-k+1})Q^{1/2} e_i \|^2 \, ds \\
&\leq C \Delta t^{4/3} \sum_{i=1}^{\infty} \| Q^{1/2} e_i \|_{s-\frac{1}{p}} \| A^{(s-\frac{1}{p})/2} Q^{1/2} \|_{L_2(H)}^2 \\
&\leq C \Delta t^{4/3} \text{Tr}(A^{s-\frac{1}{p}}) \| A^{\kappa} Q \|_{B(H)}^2.
\end{align*}
Finally, we set $-\alpha = s - \frac{1}{p} - \kappa$ and conclude that $\gamma < \frac{\alpha}{T} = (1 - \rho(\alpha - \kappa))/2$. □

Remark 4.7. In particular, if $Q = I$, then $d = 1$, $\kappa = 0$ and $\alpha > \frac{1}{2}$ whence $\gamma < 1/2 - \rho/4$. Also, note that it is clear from the proof that instead of (2.8)–(2.9) we could assume that $\| A^{(s-\frac{1}{p})/2} Q^{1/2} \|_{L_2(H)} < \infty$ and obtain $\gamma < \frac{\alpha}{T}$. Then, for trace class noise, that is, when Tr($Q$) < $\infty$, we can take $s = \frac{1}{p}$ and hence $\gamma < 1/2$. Remarkably, this is the same rate as for the heat equation [21] independently of the value of $\rho$.

5. The fully discrete scheme

In this section we derive strong error estimates for a fully discrete scheme for (2.1). Both Assumptions 1 and 2 on $b$ are needed but in return we get optimal error bounds with no initial regularity. As the fully discrete scheme, similarly to the time semidiscretization [41], we consider the recurrence
\begin{equation}
(5.1) \quad u_{n,h} - u_{n-1,h} + \Delta t \left( \sum_{k=1}^{n} \omega_{n-k} A_{h} u_{k,h} \right) = P_h(W^Q(t_n) - W^Q(t_{n-1})), \quad n \geq 1,
\end{equation}
with $u_{0,h} = P_h u_0$. Again, the solution is given by the discrete variation of constants formula,
\begin{equation}
(5.2) \quad u_{n,h} = B_{n,h} P_h u_0 + \sum_{k=0}^{n-1} B_{n-k,h} P_h \Delta W_{k+1}^Q,
\end{equation}
where $\Delta W_{k+1} = W(t_{k+1}) - W(t_k)$ and $\{ B_{k,h} \}_{k \geq 0}$ is a family of linear bounded operators with $B_{0,h} = I$.

Theorem 5.1. Let $A$ and $Q$ satisfy (2.8)–(2.9) and let $b$ satisfy Assumptions 1 and 2. Suppose further that $E(\| u_0 \|^2) < \infty$. For $T > 0$, let $\{ u(t) \}_{t \in [0,T]}$ be the unique weak solution of (2.1) and let $u_{n,h}$ be the solution of the scheme (5.1) with $T = n \Delta t$. If (3.6) holds, then there is $C = C(\rho, E(\| u_0 \|^2)) > 0$ and $K = K(T, \alpha, \gamma, \kappa, \rho) > 0$ such that
\begin{equation}
(5.3) \quad (E(\| u(T) - u_{n,h} \|^2))^{1/2} \leq C(\Delta t T^{-1} + h^2 T^{-\rho}) + K(\Delta t^\gamma + h^\nu), \quad n \Delta t = T,
\end{equation}
where $\gamma < (1 - \rho(\alpha - \kappa))/2$ and $\nu \leq \frac{\alpha}{T} - \alpha + \kappa$. 

License or copyright restrictions may apply to redistribution; see https://www.ams.org/journal-terms-of-use
Proof. We decompose the error as
\[ u(T) - u_{n,h} = S(T)u_0 - B_{n,h}P_h u_0 + \int_0^T S(T-s) dW^Q(s) - \int_0^T S_h(T-s) P_h dW^Q(s) + \int_0^T S_h(T-s) P_h dW^Q(s) - \sum_{k=0}^{n-1} B_{n-k,h} P_h \Delta W^Q_{k+1} \]
\[ := e_1 + e_2 + e_3. \]

First we bound \( e_1 \) which is the deterministic error. Under Assumptions \([1] \) and \([2] \) we have that
\[ (\mathbb{E}\|e_1\|^2)^{1/2} \leq C(\Delta t T^{-1} + h^2 T^{-\beta - 1}) (\mathbb{E}\|u_0\|^2)^{1/2} \]
by \([12] \) Theorems 2.1 and 3.2. Next, \( e_2 \) has already been bounded in \([3,12] \) as
\[ \mathbb{E}\|e_2\|^2 \leq C h^{2\nu} \|A^{(s-\frac{1}{2})/2} Q^{1/2}\|^2 \|
\]
Finally, the proof of Theorem \([4,6] \) shows that
\[ \mathbb{E}\|e_3\|^2 \leq C \Delta t^{2\gamma} \|A^{(s-\frac{1}{2})/2} (P_h Q P_h)^{1/2}\|^2 \|
\]
Set \(-r = (s - \frac{1}{2})/2\) and note that since \(0 < s \leq \frac{1}{2}\), we have that \(0 \leq r < 1/2\). Then
\[ \|A_h^{-r} (P_h Q P_h)^{1/2}\|^2 \|_{L^2(H)} = \text{Tr}(P_h A_h^{-r} P_h Q P_h A_h^{-r} P_h) = \|A_h^{-r} P_h Q^{1/2}\|^2 \|
\]
\[ \leq \|A_h^{-r} P_h A^r\|^2 \|_{B(H)} \|A^{-r} Q^{1/2}\|^2 \|_{L^2(H)}. \]

Thanks to \([3,3] \) with \(\delta = r \in [0,1/2]\), it follows that \(\|A_h^{-r} P_h A^r\|_{B(H)} \leq 1\). Hence,
\[ \mathbb{E}\|e_3\|^2 \leq C \Delta t^{2\gamma} \|A^{(s-\frac{1}{2})/2} Q^{1/2}\|^2 \|_{L^2(H)} \leq C \Delta t^{2\gamma} \text{Tr}(A^{s-\frac{1}{2}-\delta}) \|A^{-\nu} Q\|^2 \|_{B(H)}, \]
and the proof is complete. \(\square\)

Remark 5.2. We would like to highlight two important special cases. First, if \(Q = I\), then \(d = 1\), \(\kappa = 0\) and \(\alpha \geq \frac{1}{2}\). Hence \(\nu < \frac{1}{\rho} - \frac{1}{2}\) and \(\gamma < 1/2 - \frac{\nu}{2}\). As before, we could assume that \(\|A^{(s-\frac{1}{2})/2} Q^{1/2}\|_{L^2(H)} < \infty\) instead of \([2.8] \) and \([2.9] \) and get a convergence rate of order \(\nu\) is space and \(\gamma < \frac{\nu}{2}\) in time. In particular, if \(\text{Tr}(Q) < \infty\), then we may set \(\nu = \frac{1}{\rho}\). Thus, the time order is almost 1/2, the same as for the heat equation with trace class noise, but the space order is less than 1, which is the space order for the heat equation; see \([21] \).

Remark 5.3. The pure time-discretization as well as the fully discrete scheme can be studied for smooth initial data under Assumptions \([1] \) and \([2] \) on \(b\). Using \([13] \) Theorem 3.1 and \([12] \) Lemma 3.2 one arrives at the deterministic estimate
\[ \|S(T)u_0 - B_{n,h}P_h u_0\|
\]
\[ \leq C(T)(h^2 + k) \left(\|u_0\|_2 + \int_0^T \|\dot{S}(s)u_0\|_2 ds + \int_0^T \|\dot{S}(s)u_0\| ds \right). \]

If \(u_0 \in D(A)\), then \(u(t) = S(t)u_0\) is a strong solution of \([2.10] \) (see \([17] \) Proposition 1.2); that is, \(u(t) = S(t)u_0\) satisfies \([2.10] \) with \(f = 0\) for all \(t > 0\). Then
\[ \dot{S}(t)u_0 + \int_0^t b(t-s)A \dot{S}(s)u_0 ds + b(t)Au_0 = 0, \quad t > 0, \]
and thus
\[
\int_0^T \| \ddot{S}(s) u_0 \| ds \leq C(T) \left( \int_0^T \| \dot{S}(s) u_0 \|_2 ds + \| u_0 \|_2 \right).
\]

Therefore, using stability, interpolation and \((3.11)\), it follows that
\[
\| S(T) u_0 - B_{n,h} P_n u_0 \| \leq C(T, \varepsilon) (h^s + k^{s/2}) \| u_0 \|_{s(1+\varepsilon)}, \quad 0 \leq s \leq 2.
\]
The latter estimate can be used to replace the first term in the bound \((5.3)\) in the case \(\mathbb{E} \| u_0 \|_{s(1+\varepsilon)} < \infty, \quad 0 \leq s \leq 2\). The estimates for the pure time-discretization are analogous using \([12\text{, Theorem 3.1}]\) which states \((5.6)\) with \(h = 0\) and \(B_{n,0} = B_n\).
