APPLICATION OF MODAL FILTERING TO A SPECTRAL DIFFERENCE METHOD

JAN GLAUBITZ, PHILIPP ÖFFNER, AND THOMAS SONAR

Abstract. We adapt the spectral viscosity (SV) formulation implemented as a modal filter to a Spectral Difference Method (SD) solving hyperbolic conservation laws. In the SD Method we use selections of different orthogonal polynomials (APK polynomials). Furthermore we obtain new error bounds for filtered APK extensions of smooth functions. We demonstrate that the modal filter also depends on the chosen polynomial basis in the SD Method. Spectral filtering stabilizes the scheme and leaves weaker oscillations. Hence, the selection of the family of orthogonal polynomials on triangles and their specific modal filter possesses a positive influence on the stability and accuracy of the SD Method. In the second part, we initiate a stability analysis for a linear scalar test case with periodic initial condition to find the best selection of APK polynomials and their specific modal filter. To the best of our knowledge, this work is the first that gives a stability analysis for a scheme with spectral filtering. Finally, we demonstrate the influence of the underlying basis of APK polynomials in a well-known test case.

1. INTRODUCTION

In the field of Computational Fluid Dynamics (CFD), low-order methods are generally robust and reliable and therefore employed in practical calculations. The main advantage of high-order methods towards low-order methods is the possibility of considerably more accurate solutions with the same computing cost, but unfortunately they are less robust and more complicated. In recent years many researchers have focussed on this topic. There has been a surge of research activities to improve and refine high-order methods as well as to develop new ones with more favorable properties. The Spectral Difference (SD) Method for simplex cells was first presented by Liu et al. [24], and later extended by Wang et al. [37][46].

For one-dimensional, two-dimensional quadrilateral and three-dimensional hexahedral grids, the classical SD Method is identical to the multi-domain staggered grid spectral element method proposed by Kopriva et al. [22][23]. Further contributions can be found inter alia in [14][27][50]. There are many publications that show that the classical SD Method is closely related to the Discontinuous Galerkin (DG) Method and Spectral Volume Method (or the same); see [1][15][16][18][39][45][49] for example. Depending on how the degrees of freedom (DOFs) are chosen, various method implementations have different numerical properties and efficiencies. But all of them have in common that they use piecewise continuous functions as approximation space for solutions. Here, we apply the classical orthogonal polynomials

Key words and phrases. Hyperbolic conservation laws, high order methods, Spectral Difference Method, orthogonal polynomials, modal filtering.
on triangles in a Spectral Difference Method and focus on filtering techniques. We do not use the nowadays more common Flux Reconstruction (FR) or Correction Procedure via Reconstruction (CPR) methods, because we only want to investigate the pure influence of the orthogonal polynomials and their natural filters. In the FR/CPR approach, a correction term is applied which works at the interface and rectifies the calculation in every step; for details see [9, 15, 17, 34, 35, 42, 43] and references therein. Furthermore, the SD Method on triangular grids is not stable, i.e., numerical solutions might exceed all boundaries where they shouldn’t. This allows us to observe the influence of filter techniques and how they enable us to use milder such instabilities of the scheme. The SD Method combines the basic ideas of spectral methods and finite differences. It directly reconstructs a flux polynomial based on fluxes on a given nodal set called flux points. Then the derivatives of the flux polynomial are used to update the solutions at the solution points. This approach prevents the use of quadrature rules as in a normal DG or Spectral Volume ansatz. However, the SD Method has stability issues especially for high orders or if discontinuities arise in the solution. The root of the instability is that the nonlinear flux function is represented by an insufficient number of points. This introduces aliasing errors [20]. By increasing the dissipation we are able to mask such an aliasing problem. We apply the same approach as in spectral methods and use spectral viscosity to stabilize the calculation; see [26, 38]. As suggested in [25], the spectral viscosity can be carried out within the spectral filtering framework, resulting in an efficient computational implementation. The Spectral Viscosity Method (SV) can be seen as a spectral method, but at each time step the numerical solution is filtered by an exponential filter which depends on the chosen set of orthogonal polynomials.

Meister et al. [28] apply the Proriol-Koornwinder-Dubiner (PKD) polynomials in a DG Method and derive a relation between a modal filter for DG Methods on unstructured triangulation grids and the introduction of spectral viscosity to the scheme. The basic idea is to add a high-order viscosity term, which is based on the Sturm-Liouville Operator of the polynomials to the equation.

In this article, we consider the Spectral Difference Method as described in [48], but we extend it by the general classical orthogonal polynomials on triangles (APK polynomials) and their specific modal filters. With the differential operator of the APK polynomials we show, analogous to [28], the close relation between SV and spectral filtering in the SD Method.

In a theoretical framework we prove some new upper bounds for the filtered APK expansion of smooth functions. Here, we generalize the theoretical results from [28], where only the properties of the filtered PKD expansion were analyzed. Our viscosity term depends on the differential operator of the chosen polynomial set and so the exponential filter as well. Therefore the selection of the orthogonal polynomials and their natural filter have a positive impact on the stability and accuracy of the method. By starting a stability analysis as presented in [15, 40] we get a better understanding of the influence of the orthogonal polynomials and their specific filters.

---

1 With appropriate choices of correction terms, the FR framework recovers specific DG, SD, as well as spectral volume schemes.

2 There exists also quadrature-free implementations of DG; see for example [2].

3 The PKD or Dubiner polynomials are only one specific family of these polynomials.
This paper is organized as follows:

In Section 2 we will define these considered polynomials and review some properties. We will repeat the main ideas on the Spectral Difference Method and explain our implementation in the next section. High-order filters as the SV Method as a stabilizing technique are introduced in Section 4. Also, we prove an error bound for the filtered APK expansion of smooth functions and transfer the SV modification to our SD Method. In Section 5 we start with the stability analysis for our SD Method. A numerical experiment is presented before a conclusion and an outlook for future work finishes this paper.

2. Appell-Proriol-Koornwinder polynomials and their properties

In this section we introduce the orthogonal polynomials under observation. We call the family of classical orthogonal polynomials on triangles Appell-Proriol-Koornwinder polynomials (APK polynomials). In [30] the authors prove spectral convergence for the APK series. Their result gives us the theoretical foundation to use these polynomials in a spectral method.

Let $P_{\alpha,\beta}^n(x)$ be the $n$-th Jacobi polynomial, let $T := \{(x,y) \in \mathbb{R}^2 | x \geq 0, y \geq 0, x + y \leq 1\}$ be the unit triangle, and let $h(x,y) := x^{\alpha-1}y^{\beta-1}(1-x-y)^{\gamma-\alpha-\beta}$ ($\alpha, \beta, \gamma \in \mathbb{N}, \gamma > \alpha + \beta - 1$ and $\mathbb{N} = \{1, 2, \ldots\}$) be the weight function, given in this domain.

For the sake of brevity, we introduce $p = \gamma - \alpha - \beta$ and $a_l = p + \beta + 2l$.

Note that we only use $\alpha, \beta, \gamma \in \mathbb{N}$ for simplicity. In principle, $\alpha, \beta, \gamma \in \mathbb{R}^+$ is possible.

Definition 2.1. The polynomials $A_{m,l}(x,y)$, $m, l \in \mathbb{N}_0$, defined as

$$A_{m,l}(x,y) := P_{m-1,a_l}^\alpha (1 - 2x)P_{l}^{p,\beta-1}\left(\frac{2y}{1-x} - 1\right)(1-x)^l$$

on $T$ are called Appell-Proriol-Koornwinder polynomials (APK polynomials).

If the triangle $T := \{(x,y) \in \mathbb{R}^2 | x \geq -1, y \geq -1, x + y \leq 0\}$ is used instead, then (2.1) transforms to

$$\tilde{A}_{m,k}(x,y) = P_{m-1,2l+\gamma-\alpha}^{-1\,a_l}(x)P_{l}^{\gamma-\alpha-\beta,\beta-1}\left(\frac{2(y+1)}{1-x} - 1\right)\left(1-x\right)^l.$$ 

The special case $\alpha = \beta = 1$ and $\gamma = 2$ is called Proriol-Koornwinder-Dubiner polynomial (PKD polynomials); see [6,19].

These are the classical orthogonal polynomials on triangles. Details of their properties can be found in [7,21,36]. We start with the definition of the function spaces and norms we are dealing with. Then we summarize some of the properties of APK polynomials and give a couple of estimates, which are needed in the sequel. The detailed proofs of these estimates can be found in [30].

Definition 2.2. Let $h(x,y)$ be the weight function on the triangle $T$. We denote by $L^2(T, h)$ the Hilbert space with the inner product

$$(u, v) := \int_T h(x,y)u(x,y)v(x,y)dxdy$$

which induces the weighted norm

$$||u||_{L^2(T, h)} := \left(\int_T h(x,y)|u(x,y)|^2dxdy\right)^{\frac{1}{2}}.$$
We introduce by $H^m(T, h)$ a weighted Sobolev space. More precisely, we set

$$H^m(T, h) := \{ v \in L^2(T, h) : \text{for each nonnegative multi-index } \sigma \text{ with } |\sigma| \leq m, \text{ the distributional derivative } D^\sigma v \text{ belongs to } L^2(T, h) \}.$$ 

The space is endowed with the norm

$$||v||_{H^m(T, h)} := \left( \sum_{|\sigma| \leq m} ||D^\sigma v||_{L^2(T, h)}^2 \right)^{1/2}.$$ 

The APK polynomials are characterized by the integers $m$ and $l$ as can be seen in the definition. The degree of an APK polynomial is then $m + l$. Furthermore the APK polynomials are orthogonal in $L^2(T, h)$, i.e.,

$$(A_{m,l}, A_{n,s}) = \delta_{m,n} \delta_{l,s} \frac{1}{(2l + \gamma - \alpha)(2(m + l) + \gamma)\kappa_{l,m}^2},$$

with

$$\kappa_{l,m} := \sqrt{\frac{(l + \beta)p(m + a_l)\alpha}{(l + 1)p(m)\alpha(m + a_l)}},$$

where

$$\xi_0 = 1, \xi_j = \prod_{i=0}^{j}(\xi + i - 1) \text{ for } j \in \mathbb{N}$$

is the usual Pochhammer symbol. See [36, Chapter X, pp. 288ff].

Another important property of the APK polynomials can be found in the fact that they are solutions to the eigenvalue problem

$$DA_{m,l} = \lambda_{m,l} A_{m,l},$$

where the differential operator $D$ is given by

$$(x^2 - x) \frac{\partial^2}{\partial x^2} + 2xy \frac{\partial^2}{\partial x \partial y} + (y^2 - y) \frac{\partial^2}{\partial y^2} + [(\gamma + 1)x - \alpha] \frac{\partial}{\partial x} + [(\gamma + 1)y - \beta] \frac{\partial}{\partial y},$$

and the eigenvalue $\lambda_{m,l} = (m + l)(m + l + \gamma)$; see [7, p. 46]. Note that this eigenvalue equation is not a Sturm-Liouville problem and also that the differential operator is not self-adjoint for all choices of $\alpha, \beta, \gamma$. It is only self-adjoint if $\alpha = \beta = 1$ and $\gamma = 2$. But in fact, the operator is, what is called, potentially self-adjoint in $\mathring{T}$; see [36, p. 136]. Hence there exists a positive $C^2$-function $g$, $(x, y) \mapsto g(x, y)$, so that $gD$ is self-adjoint in $\mathring{T}$. This will be important in Section 4 when we use the differential operator in the viscosity term. In the following lemma we summarize two estimates which will be needed in the proof of Theorem 4.2. The proofs can be found in [30].

**Lemma 2.3.** The following norm estimate holds for APK polynomials,

$$\frac{1}{||A_{m,l}||_{L^2(T, h)}} \leq 2(m + l + \gamma)\kappa_{l,m},$$

with $\kappa_{l,m}$ given by (2.2).
Furthermore let \((x,y) \in \overline{T}\). For all \(l,m \in \mathbb{N}_0\) the estimate

\[
|A_{m,l}(x,y)| \leq \frac{\hat{D}(x,y)}{(2l + \beta + p)^{\frac{1}{2}}(2(m + l) + \gamma)^{\frac{1}{2}}k_{l,m}}
\]

holds, where

\[
\hat{D}(x,y) = \frac{D}{2(1-x-y)\frac{1}{2} + \frac{1}{2}y^{\frac{1}{2} + \frac{1}{2} - \frac{1}{2}}}^{\frac{1}{2} + \frac{1}{2} - \frac{1}{2}}(1-x)^{\frac{1}{2}}
\]

and \(D < 144\) is a positive constant. The value of \(A_{m,l}(1,0)\) is

\[
|A_{m,l}(1,0)| = \begin{cases} 
\left(\frac{m+\gamma-\alpha}{m}\right) & \text{if } l = 0, \\
0 & \text{else}.
\end{cases}
\]

**Remark 2.4.** Similar estimates also hold for the other edges of \(\overline{T}\) and can be seen in [30].

### 3. An extended spectral difference method

In this paper we consider two-dimensional hyperbolic conservation laws of the form

\[
\frac{\partial}{\partial t} u(x,t) = -\nabla_x F(u(x,t)), \quad (x,t) \in \Omega \times \mathbb{R}_0^+,
\]

where \(\Omega \subset \mathbb{R}^2\) is an open polygonal domain and \(u(x,t) \in \mathbb{R}^n\). Furthermore, initial conditions \(u(x,0) = u_0(x)\) and appropriate boundary conditions are assumed to be given.

Hence, let \(\mathcal{T}_h\) be a conforming triangulation of the closure \(\overline{\Omega}\) of the computational domain and let \(\mathbb{P}^h\) be the piecewise polynomial space defined by \(\mathbb{P}^h = \{v_h|_{\tau_i} \in \mathcal{P}^N(\tau_i), \ \forall \tau_i \in \mathcal{T}_h\}\), where \(\mathcal{P}^N(\tau_i)\) denotes the space of all polynomials on \(\tau_i\) of degree less than or equal to \(N\).

The classical Spectral Difference Method, which has been proposed by Liu [24] in 2006, can be seen as a FR or collocation method. The basic idea of this method is to discretize the right-hand side of the underlying conservation law (3.1) at certain solution points \(x_j\) in each cell. Then, the resulting ODEs (in \(t\)) at each \(x_j\) can be solved by an arbitrary explicit time-stepping scheme. Here we used the fourth-order low storage Runge-Kutta scheme defined by Carpenter and Kennedy; see [15]. We say that a scheme is of order \(N + 1\), when it is exact for \(u \in [\mathcal{P}^N]^n\).

Since the derivate of the flux \(F\) is applied to update \(u\), one needs to be exact for \(F \in [\mathcal{P}^{N+1}]^{n \times 2}\). We approximate the flux \(F\) in each element \(\tau_i\) of our triangulation \(\mathcal{T}_h\) using the basis polynomials \(\phi_k\) in the following way:

\[
(F_1(x,t), F_2(x,t)) = \sum_{k=1}^{K_F} \left[\frac{\hat{F}_{k,1}(t)}{\hat{F}_{k,2}(t)}\right] \phi_k(x).
\]

The classical approach uses Lagrange polynomials \(L_k\) with corresponding coefficients \(\hat{F}_{k,v}(t) = F_v(x_k, t)\) for \(v = 1, 2\), where \(x_k\) are chosen flux points. If we want to achieve a method of order \(N + 1\), we need the reconstruction of the solution \(u\) to lie in \([\mathcal{P}^N]^n\) and the reconstruction of the flux \(F\) to lie in \([\mathcal{P}^{N+1}]^{n \times 2}\). Hence we need \(K_s := \frac{(N+1)(N+2)}{2}\) solution points \(x_j\) and \(K_F := \frac{(N+2)(N+3)}{2}\) flux points \(x_k\). That means points where the flux value is computed. Here we apply the classic orthogonal polynomials on triangles \(\phi_k = A_{m,t}\) (in lexicographic order \(k\)).
order to adapt the polynomial basis \( \phi_k \) to every triangular cell \( \tau_i \), we introduce an orientation-preserving affine transformation \( T_i \) which maps an arbitrary triangle \( \tau_i \) to the standard triangle \( T \) of the orthogonal basis \( \phi_k \); see Figure 1. By linearity of the differential operator, inserting (3.2) into (3.1) leads to

\[
\dot{u}(x,t) = -K_F \sum_{k=1}^{K_F} \left( \dot{\hat{F}}_{k,1}(t) \xi \phi_k(T_i(x)) + \dot{\hat{F}}_{k,2}(t) \eta \phi_k(T_i(x)) \right).
\]

Applying the transformation and the chain rule to

\[
\nabla_x \phi_k(T_i(x)) = J_{T_i} \nabla_\xi \phi_k(T_i(x))
\]

finally leads to the universal update scheme

(3.3) \[
\dot{u}(x,t) = -K_F \sum_{k=1}^{K_F} \left( \dot{\hat{F}}_{k,1}(t) \xi \phi_k(T_i(x)) + \dot{\hat{F}}_{k,2}(t) \eta \phi_k(T_i(x)) \right),
\]

where for each cell only the Jacobian \( J_{T_i} \) has to be stored.

For the stability analysis in Section 5 we will derive benefit from the following matrix representation of (3.3). If we denote the vector \( \dot{u}_s(x_j,t) \) at the \( K_s \) solution points \( x_j \) by \( \frac{\text{d}u^s}{\text{d}t} \) and \( J_{T_i} \) by \( (\xi_x, \xi_y, \eta_x, \eta_y) \), the universal update scheme reads

\[
\frac{\text{d}u^s}{\text{d}t} = -K_F \sum_{k=1}^{K_F} \left( \dot{\hat{F}}_{k,1}(t) \left[ \xi_x \partial_\xi \phi_k(T_i(x_j)) + \xi_y \partial_\eta \phi_k(T_i(x_j)) \right] + \dot{\hat{F}}_{k,2}(t) \left[ \eta_x \partial_\xi \phi_k(T_i(x_j)) + \eta_y \partial_\eta \phi_k(T_i(x_j)) \right] \right)
\]

(3.4) \[
\frac{\text{d}u^s}{\text{d}t}(t) = -\xi_x D_\xi \hat{F}_1(t) - \xi_y D_\eta \hat{F}_1(t) - \eta_x D_\xi \hat{F}_2(t) - \eta_y D_\eta \hat{F}_2(t)
\]

with

\[
D_\xi = (\partial_\xi \phi_k(T_i(x_j)))_{j,k}, \quad \hat{F}_1(t) = (\dot{\hat{F}}_{k,1}(t))_k \quad \text{and} \quad \hat{F}_2(t) = (\dot{\hat{F}}_{k,2}(t))_k.
\]

\[
D_\eta = (\partial_\eta \phi_k(T_i(x_j)))_{j,k},
\]
In spite of the Lagrange reconstruction approach where the flux coefficients are directly known we have to compute \( \hat{F}_{k, \nu}(t) \), in every time step. We choose an interpolation approach, i.e., we interpolate the values of the flux function at certain flux points \( \{\mathbf{x}_k\} \) from the given flux \( F \), which will be specified later on. The nodal set \( \{\mathbf{x}_k\} \) is chosen as the set of two-dimensional Lobatto points on a triangle (see Figure 2), proposed by Blyth and Pozrikidis since they are easy to implement and have good interpolation properties as, for instance, a low condition number.

The condition number of the Vandermonde matrix \( V \) in the interpolation approach depends on the parameters \( \alpha, \beta \) and \( \gamma \) of the APK polynomials; see Table 1. The numbers in the braces describe the parameters \( (\alpha, \beta, \gamma) \) of the APK-polynomials. We realize that Lagrange polynomials lead to completely bad conditioned basis compared to any of the considered APK families. Regarding this, one should note that the coefficients of the Lagrange reconstruction are directly obtained from the values of the flux at the solution points by Lagrange interpolation. Additional numerical errors might arise.

**Table 1. Condition numbers \( \kappa_N \)**

</table>

Additionally, enough flux points lie on the edges of an element to ensure global conservation, which is then realized by replacing the original flux \( F \) at flux points \( \mathbf{x}_k \) at the edges by a numerical flux \( F_{\text{num}} \) whose normal component is computed from a numerical flux function \( H \), i.e., \( F_{\text{num}} \cdot \mathbf{n} = H(\mathbf{u}_-(\mathbf{x}_k, t), \mathbf{u}_+(\mathbf{x}_k, t), \mathbf{n}) \). The whole flux is used in the scheme, so that one needs a second condition to determine the numerical flux. As in \( [44] \), we enforce \( F_{\text{num}} \) to maintain the same tangential component as the original flux, i.e., \( F_{\text{num}} \cdot \mathbf{t} = F(\mathbf{u}(\mathbf{x}_k, t)) \cdot \mathbf{t} \), which uniquely defines the numerical flux \( F_{\text{num}} = (F_{k,1}^{\text{num}} F_{k,2}^{\text{num}})^T \) at each edge point \( \mathbf{x}_k \). Now, the coefficients \( \hat{F}_{k, \nu}(t) \) in equation (3.3) can be computed by solving the system of equation \( \mathbf{F}_\nu(t) = \mathbf{V} \cdot \hat{\mathbf{F}}_\nu(t) \) for each component \( \nu = 1, 2 \), where \( \hat{\mathbf{F}}_\nu = \left(\hat{F}_{k, \nu}(t)\right)_k \), \( \mathbf{V} = (\phi_k(\mathbf{x}_j))_{j,k} \) is the Vandermonde matrix and \( \mathbf{F}_\nu(t) = (F_{k, \nu})_k \).
is given by
\begin{equation}
F_{k,\nu} = \begin{cases} 
F_{\nu}(u(x_k, t)), & \text{if } x_k \in \bar{\tau}_i, \\
F_{\text{num}}^{k,\nu}, & \text{if } x_k \in \partial \tau_i.
\end{cases}
\end{equation}

If we apply this to (3.4) the universal update scheme reads
\begin{equation}
\frac{du^s}{dt}(t) = -(\xi_x D_x + \xi_y D_y) V^{-1} F_1(t) - (\eta_x D_x + \eta_y D_y) V^{-1} F_2(t)
\end{equation}
in a matrix representation. In Section 5 we will use this result to obtain the form
\begin{equation}
\frac{du^s}{dt}(t) = S u^s(t)
\end{equation}
with a matrix $S$ for a suitable test case. In the numerical examples in Section 6 we will use the Godunov flux
\begin{equation}
H(u_-, u_+, n) = \begin{cases} 
\min_{u_- \leq u \leq u_+} F(u) \cdot n, & \text{if } u_- \leq u_+, \\
\max_{u_+ \leq u \leq u_-} F(u) \cdot n, & \text{else},
\end{cases}
\end{equation}
in the scalar case for the numerical flux function. The Godunov flux is an Upwind flux. For the linear transport equation we obtain the numerical flux
\begin{equation}
H(u_-, u_+, n) = \begin{cases} 
(a \cdot n) u_-, & (a \cdot n) \geq 0, \\
(a \cdot n) u_+, & (a \cdot n) < 0.
\end{cases}
\end{equation}

We will apply this numerical flux function in the stability analysis in Section 5 as well. For a more detailed explanation of the Spectral Difference Method and the extension see [47]. Yet, to at least highlight a significant advantage of the Spectral Difference Method, we observe the experimental order of convergence (EOC) in the $L_\infty$-norm for the linear advection equation
\begin{equation}
\frac{\partial}{\partial t} u(x, t) = -\frac{\partial}{\partial x} u(x, t) - \frac{\partial}{\partial y} u(x, t) \text{ with } (x, t) \in [-1, 1]^2 \times [0, 0.5]
\end{equation}
and for the smooth initial condition $u(x, 0) = \sin \pi (x + y)$. In Table 2 this is done with respect to both the number of triangles (EOC$(k)$) and the degree of the polynomial approximation in each triangle (EOC$(N)$). For these approximations the parameters $(\alpha, \beta, \gamma) = (2, 2, 5)$ were chosen. Note that for unstructured triangulations some measurement $h$ for the size of the triangles should be used for the rate of convergence. Here for example, $h$ was the biggest volume of the triangles. At the same time however, in this test, $h$ was directly inversely proportional to $k$, i.e., $h = \text{const} \cdot \frac{k}{k}$. Thus EOC$(h)$ is equal to EOC$(k)$. For the sake of simplicity:

</table>

We therefore observed convergence in the number of triangles $k$ and not their size $h$.

Table 2 clearly indicates the rate of convergence to be considerably higher when increasing the polynomial degree instead of refining the triangulation. For sufficiently smooth solutions, schemes using a polynomial approximation, in fact, often provide significantly higher rates of convergence than classical ones, where low degrees (in particular 0) are used. Note that in Table 2 the same behavior can be observed for for the $L_1$- and $L_2$-norm.
The filtering process

In the conservation law, discontinuities may arise in the solution. Using a series expansion

$$P_N u(x,y) = \sum_{l,m \leq N, l,m \in \mathbb{N}_0} \tilde{u}_{m,l} \tilde{A}_{m,l}(x,y), \quad \tilde{u}_{m,l} = \frac{(u; A_{m,l})_{L^2(T,h)}}{(A_{m,l}; A_{m,l})_{L^2(T,h)}},$$

to approximate the solution leads to spurious oscillations in the vicinity of discontinuities (called Gibbs phenomenon). The oscillations occur in the approximated solution because the high coefficients of the series expansion turn slowly to zero; see [11,12].

The aliasing error effects stability problems in the SD Method. The root of the instabilities is that the nonlinear flux function is represented by an insufficient amount of points. This introduces aliasing errors. These stability problems display especially near the oscillations. The amplitudes increase in time exceeding the error expected from the pure Gibbs phenomenon; see Section 6. A higher inherent dissipation is able to mask such an aliasing problem. By adding spectral viscosity to the equation we increase the dissipation.

To remedy the Gibbs’ effect, different approaches can be found in the literature [8,10,12,41]. A common approach is to use a modal filter, which appeals directly on the high-order coefficients of the series expansion. While multiplying a filter function to the high Fourier coefficients, the series loses its approximation properties. We prove new error bounds for the filtered APK series expansion of smooth function. We generalize the results of [28] to all series expansion with classic orthogonal polynomials on triangles. Global filtering in each cell degrades the order

### Table 2. \((\alpha, \beta, \gamma) = (2, 2, 5), \ t = 0.5s\)

</table>
of accuracy; see [28]. Therefore we apply a well-known jump indicator [33] and
transfer the SV modification to the SD Method.

4.1. Modal filters. A modal filter appeals directly to the coefficients of the series expansion.

Definition 4.1. For an integer \( p \geq 1 \) we define a filter of order \( p \) as a real function
\( \sigma \in C^{p-1}([0,1]) \) with the properties
\[
\sigma(0) = 1, \quad \sigma^{(k)}(0) = 0, \quad 1 \leq k \leq p - 1.
\]

Additionally to the properties (4.2) many authors demand the following condition for a filter of order \( p \):
\[
\sigma^{(k)}(1) = 0, \quad 0 \leq k \leq p - 1;
\]
compare [12, 41]. In [13], Hesthaven and Kirby require in addition \( \sigma \in C^{p}([0,1]) \).

A very popular filter is the exponential filter
\[
\sigma(\eta) = \exp(-\alpha \eta^p),
\]
where the filter strength \( \alpha \) yields \( \exp(-\alpha) \) in the range of the machine accuracy.

We already mentioned that there are various partial results for the approximation property of a filtered series expansion. For instance, in [41] Vandeven has analyzed the filtered Fourier expansions of a piecewise smooth function and later expanded his result to filtered Chebyshev series. On the other hand, Kirby and Hesthaven investigate the approximation property of the filtered Legendre expansion for sufficiently smooth functions in [13]. [28] expands the investigation to two-dimensional basis functions (PKD polynomials). Finally, we now complete the investigation from [28], by proving an error bound for the filtered APK partial sum. Again, we stress that the PKD polynomials are just a special case of the APK polynomials. Here we prove the most general case and consider the filtered APK expansions for sufficiently smooth functions \( u : T \rightarrow \mathbb{R} \),
\[
u_N^\sigma(x,y) = \sum_{l+m \leq N} \sigma\left(\frac{l+m}{N}\right) \tilde{u}_{m,l} A_{m,l}(x,y), \quad N \geq 1,
\]
with coefficients \( \tilde{u}_{m,l} \) given by (4.1).

Theorem 4.2. Let \( u \in H^{2k}(T,h) \cap C(T), k \in \mathbb{N}, h(x,y) = x^{\alpha-1}y^{\beta-1}(1-x-y)^p \) with \( \alpha, \beta \in \mathbb{N} \) and let \( \sigma \) be a modal filter of order \( 2k - 1 \), with the additional condition \( \sigma \in C^{2k-1}([0,\varepsilon]) \) in an interval \( [0,\varepsilon] \subset [0,1] \), \( \varepsilon > 0 \). Furthermore let \( k > \max \left\{ \frac{3}{4} + \frac{3}{2} \alpha + \frac{p}{2}, \frac{5}{4} + \frac{p+\beta}{2} \right\} \).

Then we obtain the pointwise error bounds with constants \( K_1 - K_6 \):

1. If \( (x,y) \in \overset{\circ}{T} \), the error is
\[
|u(x,y) - \nu_N^\sigma(x,y)| \leq K_1 \frac{1}{N^{2k - \frac{3}{4}}},
\]

2. On the left edge \([0,y]\) with \( y \in [0,1] \) we obtain
\[
|u(0,y) - \nu_N^\sigma(0,y)| \leq \begin{cases} 
K_2 \frac{1}{N^{2k - \frac{3}{2} \alpha - p - \frac{1}{2}}}, & \text{for } p > \beta - 1, \\
K_3 \frac{1}{N^{2k - \frac{3}{2} \alpha - \beta + \frac{1}{2}}}, & \text{for } p \leq \beta - 1.
\end{cases}
\]
(3) On the edge $[x, 0]$ with $x \in (0, 1)$ the error is
\[ |u(x, 0) - u_N^\sigma(x, 0)| \leq K_4 \frac{1}{N^{2k-\frac{4}{\beta}}}. \]

(4) On the hypotenuse $[x, 1-x]$ with $x \in (0, 1)$ we obtain
\[ |u(x, 1-x) - u_N^\sigma(x, 1-x)| \leq K_5 \frac{1}{N^{2k-\frac{4}{\beta}}}. \]

(5) In the point $(1,0)$ we preserve
\[ |u(1,0) - u_N^\sigma(1,0)| \leq K_6 \frac{1}{N^{2k+\alpha-\gamma-\frac{4}{2}}}. \]

Proof. We start the proof similarly to [30, Theorem 3.1]. Let $m + l \neq 0$; then
\[ (A_{m,l}; A_{m,l})_{L^2(T,h)} \cdot |\tilde{u}_{m,l}| = (u; A_{m,l})_{L^2(T,h)} \leq \frac{1}{\lambda_{m,l}} (gD; A_{m,l})_{L^2(T,h)} \]
holds. We use the fact that the differential operator $D$ is potentially self-adjoint in $T$ and that the boundary is a set of measure zero. Due to the operator $D$ to be potentially self-adjoint, we find a positive $C^2$-function $g$ so that $gD$ is self-adjoint, $\frac{1}{g}$ is well defined and symmetric. So we get
\[ (u; \frac{DA_{m,l}}{\lambda_{m,l}})_{L^2(T,h)} = \left( u; \frac{(gD)A_{m,l}}{\lambda_{m,l}} \right)_{L^2(T,h)} = \left( \frac{1}{\lambda_{m,l}} (gD)u; A_{m,l} \right)_{L^2(T,h)} \]
and hence have shown
\[ (A_{m,l}; A_{m,l})_{L^2(T,h)} \cdot |\tilde{u}_{m,l}| = \left( \frac{1}{\lambda_{m,l}} \right)^k (D^k u; A_{m,l})_{L^2(T,h)}, \]

By this and since
\[ u(x, y) = \sum_{m,l \in \mathbb{N}_0} \tilde{u}_{m,l} A_{m,l}(x, y) \]
is satisfied for every point $(x, y) \in T$ (see [30 equation (18)]), we get
\[ |u(x, y) - u_N^\sigma(x, y)| = \left| \sum_{0 \leq l+m \leq N \atop l, m \in \mathbb{N}_0} \left( 1 - \sigma \left( \frac{l+m}{N} \right) \right) \tilde{u}_{m,l} A_{m,l}(x, y) + \sum_{l+m > N \atop l, m \in \mathbb{N}_0} \tilde{u}_{m,l} A_{m,l}(x, y) \right| \]
\[ = \left| \int_T h(x_1, y_1) [S_N(x, y, x_1, y_1) + R_N(x, y, x_1, y_1)] D^k u(x_1, y_1) \, dx_1 \, dy_1 \right|, \]
for the function $u$, where $S_N(x, y, x_1, y_1)$ and $R_N(x, y, x_1, y_1)$ are defined by
\[ S_N(x, y, x_1, y_1) = \sum_{1 \leq l+m \leq N \atop l, m \in \mathbb{N}_0} \left( 1 - \sigma \left( \frac{l+m}{N} \right) \right) \frac{A_{m,l}(x_1, y_1) A_{m,l}(x, y)}{||A_{m,l}||_{L^2(T,h)}^2 \lambda_{m,l}^k}, \]
\[ R_N(x, y, x_1, y_1) = \sum_{l+m > N \atop l, m \in \mathbb{N}_0} \frac{A_{m,l}(x_1, y_1) A_{m,l}(x, y)}{||A_{m,l}||_{L^2(T,h)}^2 \lambda_{m,l}^k}. \]
as well as elementary estimates leads to

\[
\sum_{1 \leq l+m \leq N} \left( 1 - \sigma \frac{l + m}{N} \right)^2 \frac{A_{m,l}^2(x,y)}{|A_{m,l}|^2_{\mathbb{L}^2(\mathbb{T},h)}} \cdot \kappa_{m,l}^2 4(m + l + \gamma)^2 \tilde{E}^2(x,y) \frac{1}{(m + l)^{2k+\frac{7}{2} + \frac{\gamma}{4} + p}}\]

Using the identity

\[
\sum_{0 < l+m \leq N} \left( \frac{1}{m+l} \right)^k = \sum_{i=1}^{N} \frac{i+1}{i^k}
\]

as well as elementary estimates leads to

\[
\sum_{1 \leq l+m \leq N} \left( 1 - \sigma \frac{l + m}{N} \right)^2 \frac{1}{|A_{m,l}|^2_{\mathbb{L}^2(\mathbb{T},h)}} \cdot \kappa_{m,l}^2 4(m + l + \gamma)^2 \tilde{E}^2(x,y) \frac{1}{(m + l)^{2k+\frac{7}{2} + \frac{\gamma}{4} + p}}\]

If \( N \to \infty \), the last factor conforms with the integral

\[
\int_0^1 (1 - \sigma(\tau))^2 \tau^{\frac{5}{2} - 4k} d\tau.
\]

| area     | \( \max\{\left(\frac{1+p}{l}\right), \left(\frac{1+\beta-1}{l}\right)\} \) | \( ||R_N(x,y,\cdot,\cdot)||_{\mathbb{L}^2(\mathbb{T},h)} < \) |
|-----------------|---------------------------------|-------------------------------------------------|
| \( \mathbb{T} \) | \( (\frac{l+p}{l}) \)           | \( C_{R_1} N^{-2k+\frac{7}{2}} \)               |
| \( [0,y] \)     | \( (\frac{l+p}{l}) \)           | \( C_{R_2(1)} N^{-2k+\frac{7}{2} + \alpha + p + \frac{1}{2}} \) |
| \( [0,y] \)     | \( (\frac{l+p}{l}) \)           | \( C_{R_2(2)} N^{-2k+\frac{7}{2} + \alpha - \frac{1}{2}} \) |
| \( [x,0] \)     | \( (\frac{l+p}{l}) \)           | \( C_{R_3} N^{-2k+\frac{7}{2} + \beta} \)       |
| \( [x,1-x] \)   | \( (\frac{l+p}{l}) \)           | \( C_{R_4} N^{-2k+\frac{7}{2} + p} \)           |
| \( (1,0) \)     | \( (\frac{l+p}{l}) \)           | \( C_{R_5} N^{-2k - \alpha + \gamma + \frac{3}{2}} \) |

We apply the Cauchy-Schwarz inequality to estimate the integral. Therefore we have to estimate the weighted \( \mathbb{L}^2(\mathbb{T}) \)-norms of \( S_N \) and \( R_N \) for all \( (x,y) \). For the \( R_N \) we extract the results from the proof of Theorem 3.1 from \[30\]. We summarize the results in Table 3. Now we are able to estimate \( S_N \). We follow the proof of \[30\] Theorem 3.1 and start with some inner point \( (x,y) \in \mathbb{T} \):

\[
\frac{1}{|A_{m,l}|^2_{\mathbb{L}^2(\mathbb{T},h)}} \cdot \kappa_{m,l}^2 4(m + l + \gamma)^2 \tilde{E}^2(x,y) \frac{1}{(m + l)^{2k+\frac{7}{2} + \frac{\gamma}{4} + p}}\]
The integral is bounded by the given conditions. To verify this fact, we calculate the Taylor series of $\sigma$ in $0$:

$$\sigma(\tau) = \sum_{j=0}^{2k-1} \frac{1}{j!} \sigma^{(j)}(0) \tau^j + o(\tau^{2k-1}) \quad \forall \tau \in [0, \varepsilon).$$

In connection with $\sigma(0) = 1$ and $\sigma^{(j)}(0) = 0$ for all $j = 1, 2, \ldots, 2k - 2$ the term reduces to

$$\sigma(\tau) = 1 + \frac{1}{(2k - 1)!} \sigma^{(2k-1)}(0) \tau^{2k-1} + o(\tau^{2k-1})$$

for all $\tau \in [0, \varepsilon)$. Using this in the integral, we get

$$\int_0^\varepsilon \left( \frac{\sigma^{(2k-1)}(0)}{(2k - 1)!} \tau^{2k-1} + o(\tau^{2k-1}) \right)^2 \tau^{-4k+\frac{5}{2}} d\tau + \int_\varepsilon^1 (1 - \sigma(\tau))^2 \tau^{\frac{5}{2} - 4k} d\tau < C_{I_1}^2,$$

because every part is bounded. Hence,

$$\|S_N(x, y, \cdot, \cdot)\|_{L^2(T, h)} < \sqrt{8} \tilde{E}(x, y) N^{-2k+\frac{7}{2}} C_{I_1} = C_{S_1} N^{-2k+\frac{7}{2}};$$

now the formal inequality holds and with the Cauchy-Schwarz inequality we show in total that

$$|u(x, y) - u_N^\sigma(x, y)| \leq \|D_k u\|_{L^2(T, h)} (\|R_N(x, y, \cdot, \cdot)\|_{L^2(T, h)} + \|S_N(x, y, \cdot, \cdot)\|_{L^2(T, h)})$$

$$\leq (\|D_k u\|_{L^2(T, h)}(C_{R_1} + C_{S_1}) N^{-2k+\frac{7}{2}}.$$

The computations for the edges are analogously obtained. We present the results in the following table:

| edge      | max\{$(\ell + p \ell, \ell + \beta + 1 \ell)$\} | $|u(x, y) - u_N^\sigma(x, y)|$ |
|-----------|-----------------------------------------------|-----------------------------|
| $[0, y]$  | $(\ell + p \ell)$                            | $\frac{K_2}{N^{2k-4\alpha-p-\frac{5}{2}}}$ |
| $[0, y]$  | $(\ell + \beta - 1 \ell)$                    | $\frac{K_3}{N^{2k-4\alpha-\beta+\frac{5}{2}}}$ |
| $[x, 0]$  | $(\ell + \beta - 1 \ell)$                    | $\frac{K_4}{N^{2k-4\alpha-\beta+\frac{5}{2}}}$ |
| $[x, 1-x]$| $(\ell + \beta - 1 \ell)$                    | $\frac{K_5}{N^{2k-4\alpha-\beta+\frac{5}{2}}}$ |

For the last point $(1, 0)$ we calculate it directly:

$$\|S_N(1, 0, \cdot, \cdot)\|_{L^2(T, h)}^2 = \sum_{m=1}^N \left( 1 - \sigma\left( \frac{m}{N} \right) \right)^2 \frac{A_{m, 0}^2(1, 0)}{||A_{m, 0}||_{L^2(T, h)}^2} \frac{\lambda_{2k}^{2k}}{m_{2k}(m + \gamma)^{2k-2}}$$

$$< 4 \left( \frac{\beta p \gamma}{(1)_{p}} \right) \sum_{m=1}^N \left( 1 - \sigma\left( \frac{m}{N} \right) \right)^2 \frac{\left( \frac{m + \gamma - \alpha}{m} \right)^2}{m^{2k}(m + \gamma)^{2k-2}}$$

$$< C_5 \sum_{m=1}^N \left( 1 - \sigma\left( \frac{m}{N} \right) \right)^2 \frac{1}{m^{2k}(m + \gamma)^{2k-2}} \frac{N^{4k-2-2\gamma+2\alpha}}{N^{4k-2-2\gamma+2\alpha}}$$

$$< C_{S_5} N^{-4k+3+2\gamma-2\alpha} \left( \frac{1}{N} \sum_{m=1}^N \left( 1 - \sigma\left( \frac{m}{N} \right) \right)^2 \left( \frac{m}{N} \right)^{-4k+2+2\gamma-2\alpha} \right),$$
and after all it ensues that
\[ |u(1, 0) - u_N(1, 0)| < K_6 N^{-2k - \alpha + \gamma + \frac{3}{2}}. \]

To verify Theorem 4.2 we test the approximation speed. On the triangle \( T \), we approximate the function \( f(x, y) = \sin(\pi(x + y)) \) by the filtered and unfiltered truncated series expansion with respect to the APK polynomials for parameters \((\alpha, \beta, \gamma) = (1, 1, 2)\) and \((2, 2, 5)\). For the filters, we choose exponential filters (4.4) of order 2 and filter strength 0.001 and of order 4 and strength 0.00001. Furthermore, we applied the classical cosine filter
\[ \sigma(\eta) = 0.5(1 + \cos(\pi\eta)) \]
of second order. In Figure 2 the maximal errors of these truncated series expansions are illustrated with respect to the polynomial degree. \( A \) and \( E \) are the unfiltered APK expansions, \( B, F \) are the filtered APK expansions, where the exponential filter of order 2 was used, for \( C, G \) the cosine filter was used and for \( D, H \) the exponential filter of order 4 was used. Therefore, \( A \) is comparable to \( E \), \( B \) to \( F \), \( C \) to \( G \) and \( D \) to \( H \). All calculations were done in Mathematica and by its integration subroutine in order to calculate the coefficients \( \hat{u}_{m,l} \).

As Figure 2 illustrates, the highest rate of convergence is obtained by the unfiltered APK expansions. On the other hand, the APK expansions filtered by the cosine filter \((C, G)\) and the exponential filter of second order \((B, F)\) show a notably slower rate of convergence. Yet, by increasing the order of the filter and applying the exponential filter of fourth order to the APK expansion \((D, H)\), the rate of convergence significantly increases. Thus, for higher filter orders we get a stronger decrease in the max-error. In Table 4 the position and the value of the maximum-errors are plotted for \( C \) and \( G \). For the others it looks analogous.

The maximum error lies in \( \mathbb{T} \) and the error decreases with \( N^{-\frac{1}{2\pi}} \). For \( C \), \( K_1 \) has to be around 0.867428 and for \( G \), \( K_1 \) is 0.52477. In Table 5 we numerically determined the constants \( K_1, K_3, K_4, K_5 \) and \( K_6 \) for the case \( D \). All of this verifies our result.
4.2. The spectral viscosity method. Since spectral methods are known to lack sufficient dissipation, Tadmor [38] proposed the Spectral Viscosity or Super-Spectral Viscosity Method (SV Method). The main idea of the SV Method is to add a small viscosity term to the conservation law [31]. We show analogously to [25,32] that by choosing a viscosity term which depends on the differential operator of the orthogonal basis, the SV Method can be seen as a spectral method with modal filtering.

For the SD scheme based on the APK expansions, we propose to consider high-order operators of the form \((-D)^p\) on the reference element \(\mathcal{T}\). Let \(I_N\) be an index set and \(\phi_k = A_{m,l}\) the APK polynomials in lexicographic order \(k\); see Section 3.

**Theorem 4.3.** Let \(N \in \mathbb{N}\) and let \(\{\phi_k | k \in I_N\}\) be the APK polynomials on the triangle \(\mathcal{T}\). The polynomials solve the eigenvalue problem

\[
-D\phi_k = -\lambda_k \phi_k,
\]

where \(D\) is the differential operator of the polynomials. \(P_\phi\) denotes the projection on the space of \(\{\phi_k\}\). To solve the viscosity equation

\[
\frac{\partial}{\partial t} u_N(x, t) + \nabla_x \cdot P_\phi f(u_N(x, t)) = \varepsilon_N (-1)^{p+1} (-D)^p u_N(x, t)
\]

by a splitting method is equivalent to multiplying the coefficients \(\hat{u}_k\) with the function

\[
\sigma(k) = e^{-\varepsilon_N \Delta x \lambda_k^p}
\]

in every update step of the equation

\[
\frac{\partial}{\partial t} u_N(x, t) + \nabla_x \cdot P_\phi f(u_N(x, t)) = 0.
\]

**Proof.** We solve the equation (4.7) by a splitting method in two steps:

\[
\frac{\partial}{\partial t} u_N(x, t) = \varepsilon_N (-1)^{p+1} (-D)^p u_N(x, t)
\]

and

\[
\frac{\partial}{\partial t} u_N(x, t) + \nabla_x \cdot P_\phi f(u_N(x, t)) = 0.
\]
With $u_N(x, t) = \sum_{k \in I_N} \hat{u}_k \phi_k(x)$ equation (4.8) implies
\[
\sum_{k \in I_N} \frac{\partial \hat{u}_k}{\partial t} \phi_k(x) = \sum_{k \in I_N} \varepsilon_N (-1)^{p+1} \hat{u}_k (-D)^p \phi_k(x) = \sum_{k \in I_N} -\varepsilon_N \hat{u}_k(t) \lambda_k^p \phi_k(x),
\]
where we applied the eigenvalue equation (4.6) in the last step. By comparing the coefficients we have to solve the ordinary differential equations
\[
\frac{\partial \hat{u}_k(t)}{\partial t} = -\varepsilon_N \hat{u}_k(t) \lambda_k^p, \quad \forall k \in I_N.
\]
The solution is $\hat{u}_k(t) = ce^{-\varepsilon_N \lambda_k^p t}, \ c \in \mathbb{R}$. Then with $\Delta t := t^{n+1} - t^n$ and the requirement $\hat{u}_k(t^{n+1}) = \hat{u}_k(t^n)$ for $\Delta t = 0$ it follows that
\[
\hat{u}_k(t^{n+1}) = e^{-\varepsilon_N \lambda_k^p (\Delta t)} \hat{u}_k(t^n).
\]
\[
= \sigma(k)
\]

In order for us to speak of a modal filter for
\[
\sigma(k) = \sigma((l, m)) = e^{-\varepsilon_N (l+m) \gamma (l+m+\gamma)} \Delta t,
\]
we have to multiply the exponent with $N^{2p}$, meaning
\[
\sigma \left( \frac{l+m}{N} \right) = e^{-\varepsilon_N N^{2p} \gamma (l+m+\gamma) \Delta t} \approx e^{-\varepsilon_N N^{2p} \Delta t (\frac{l+m}{N})^{2p}}.
\]
Hence $\sigma : [0, 1] \rightarrow [0, 1]$ can be seen as an exponential filter of order $2p$ with filter strength $\alpha_i := -\varepsilon_N N^{2p} \Delta t$. We consider (4.10) in detail and realize that our modal filter depends on the parameter $\gamma$ of the APK polynomials, especially if the polynomials have minor degree. So for different families of APK polynomials we get various specific modal filters.

We can prove similar results to Theorem 4.3 for every orthogonal basis $\{\phi_k\}$, if the $\phi_k$ fulfill a comparable eigenvalue equation.

For the transfer of the SV Method to our Spectral Difference Method we follow the steps according to [47]. The transformation $T_i$ from $\tau_i$ to $\mathbb{T}$ has no effect on the flux function, so that the SD update scheme of a scalar hyperbolic equation in the cell $\tau_i$ with viscosity term and the solution points $\xi_j \in \mathbb{T}$ reads
\[
\frac{\partial}{\partial t} u_N(T_i^{-1}(\xi_j), t) + \nabla \xi \cdot \tilde{P}_N(J_{T_i}) \tilde{F}(u_N(T_i^{-1}(\xi_j), t))
\]
\[
= \varepsilon_N (-1)^{p+1} (-D)^p (u_N(T_i^{-1}(\xi_j), t)),
\]
where $\tilde{F}$ is the flux function, $\tilde{P}$ is the projection and $\nabla \xi$ is the nabla operator on $\mathbb{T}$. The same approach as in Theorem 4.3 yields the equivalent of (4.11) and the SD Method with the modal filter (4.10).
Hence, the matrix representation (3.7) for the SD update scheme in cell $\tau_i$ becomes
\[
\frac{d\mathbf{u}_s}{dt}(t) = - (\xi_x D_\xi + \xi_y D_\eta)(\sigma(k) \hat{F}_{k,1}(t))_k - (\eta_x D_\xi + \eta_y D_\eta)(\sigma(k) \hat{F}_{k,2}(t))_k
\]
\[
= - (\xi_x D_\xi + \xi_y D_\eta) M_\sigma \hat{F}_1(t)
- (\eta_x D_\xi + \eta_y D_\eta) M_\sigma \hat{F}_2(t)
\]
(4.12)
with viscosity, where $M_\sigma := \text{diag}(\sigma(1), \ldots, \sigma(N_F))$ is a diagonal matrix. So we have to choose the size of $\varepsilon_N$, thereby we stick to the analysis of [10]. The authors suggested in the Fourier case a viscosity strength $\varepsilon_N$, which depends on the approximation order as
\[
\varepsilon_N \sim \frac{C_p}{N^{2p-1}},
\]
where the constant $C_p$ may be chosen by
\[
C_p \leq \sum_{k=1}^p ||\partial_u^{(J_T)}(u)||_{L\infty} = \|(J_T)\|^\infty \sum_{k=1}^p ||\partial_u^{k} \hat{F}(u)||_{L\infty}.
\]
Here, we ignore the dependence on $u$ and approximate $||((J_T)^T)\|^\infty \sim \frac{1}{h_i}$ by a measure of length $h_i$ of the triangle $\tau_i$. Finally, we arrive at
\[
\varepsilon_N := \frac{c}{h_i N^{2p-1}} < \frac{\sum_{k=1}^p ||\partial_u^{k} \hat{F}(u)||_{L\infty}}{h_i N^{2p-1}},
\]
where $c \in \mathbb{R}$ is a constant. We have to select the constant $c$ and the filter order $2p$ in our numerical tests.

**Remark 4.4.** The numerical tests from [29,47] imply that we have to increase $c$ if we enlarge the filter order $2p$.

Furthermore, it is a known fact that the application of a modal filter in the global domain will destroy the order of convergence. Shock indicators are used to detect corrupted cells. There are different approaches to detect jumps in a cell; see [31,48] for example. Here we use the shock indicator of [3]. The indicator compares the higher coefficients with the lower ones to detect oscillations.

In general, the time step $\Delta t$ in the explicit time-stepping scheme[3] for the resulting ODEs (in $t$) at each solution point $x_j$, which also appears in the filter strength $\alpha_i = -\varepsilon_N N^{2p} \Delta t$ in (4.10), cannot be chosen arbitrarily. For a scalar conservation law $u_t(x,t) + \lambda u_x(x,t) = 0$ in one space dimension and a numerical scheme on a uniform grid with length $h$ one should choose $\Delta t$ small enough, so that a wave with propagation speed $\lambda$ cannot travel more than $h$ in one time step; i.e., the Courant-Friedrichs-Levy condition $\lambda \Delta t \leq h$ has to hold. The maximum
\[
\max_\lambda \frac{\lambda \Delta t}{h} =: \text{CFL}
\]
\footnote{We already mentioned, that we use the fourth-order low storage Runge-Kutta scheme defined by Carpenter and Kennedy (see [5]) in our implementation for Section [6].}
is called Courant number and the following example gives the first insight of how it can be determined on a triangulation.

**Example 4.5.** We observe the two-dimensional advection equation

\[ u_t(x, y, t) + u_x(x, y, t) + u_y(x, y, t) = 0. \]

Here the propagation speed in the (1, 1) direction is \( \sqrt{2} \), which leads to the Courant number \( CFL = \frac{\sqrt{2} \Delta t}{h} \), in which \( h \) is now a measure of length of the observed triangle.

As we can see in Section 5.2 the SD Method has stability problems for all parameters \( \alpha, \beta \) and \( \gamma \), which are increasing for rising order \( N \). Hence, we cannot even compute a sufficiently numerical Courant number and will choose the time step

\[ \Delta t := \frac{C_{fix}}{(N + 1)^2} \cdot \frac{h}{\lambda_{max}} \]

(4.14)

with a fixed value \( C_{fix} \) and maximal propagation speed \( \lambda_{max} \). Therefore, since the time step adapts an increasing instability for rising \( N \) and the “geometry” of the triangulation by \( h \) and by \( C_{fix} = \frac{1}{2} \), which will be our choice, (4.14) coincides with the Courant number in Example 4.5 for \( N = 0 \).

5. **Stability of the spectral difference method**

By von Neumann analysis in matrix form for a scalar advection equation in two spatial dimensions with periodic initial condition, one can observe the linear stability of the semi-discretization. This was already done by Abeele, Lacor and Wang for the classical SD Method in [40], by Huynh for the FR Method in [15] and many other authors. Here we observe the SD Method for APK polynomials on a triangular grid, which is generated by a pattern as in Figure 3 for a scalar advection equation

\[ u_t + \cos(\psi)u_x + \sin(\psi)u_y = 0 \]

with \( \psi \in [0, \frac{\pi}{2}] \) and the periodic initial condition

\[ u_{init}(x, y) = e^{I(w_x x + w_y y)}, \]

where \( w_x, w_y \in [-\pi, \pi] \) are the so called wave numbers in \( x \)- and \( y \)-direction. The exact solution is then given by

\[ u_{exact}(x, y, t) = e^{I(w_x x + w_y y - [w_x \cos \psi + w_y \sin \psi]t)} \]

(5.1)

for \( t \geq 0 \). We will concentrate on the semi-discretization at \( t = 0 \) and we wish to obtain a relation in the form of a linear ODE system

\[ \frac{du^s}{dt} = Su^s \]

(5.2)

of first order and with constant coefficients in the solution points. Similarly to the scalar case \( \frac{du}{dt} = \lambda u \), where the solution is given by \( u(t) = ce^{\lambda t} \) for \( c \in \mathbb{R} \), the eigenvalues of the matrix \( S \) take the place of \( \lambda \). Hence the asymptotic behavior of the solution of (5.2) depends on the real parts of the eigenvalues: If all eigenvalues of \( S \) lie in the left half of the complex plane, the solution is bounded, which coincides with the behavior of the exact solution \( u_{exact} \). In this case we call the semi-discretization to be stable. On the other hand, if any eigenvalue lies in the right half of the complex plane, the solution of (5.2) will blow up for \( t \to \infty \) and so might the scheme. This will happen unless the instability is mild, i.e., \( \max_\lambda \Re(\lambda) \) is
small, and the time steps adapt to this and are sufficiently small. In 5.1 we will first derive a matrix representation like (5.2) for the SD scheme at $t = 0$ and for the test case above. In 5.2 we will analyze the stability of the unfiltered SD scheme from Section 3 for certain ranges for $\alpha, \beta$ and $\gamma$. By observation of the numerical test cases, one can see that some stabilization is necessary and we did so in Section 4 by the SV Method in terms of the SD Method with modal filtering. Following this, in 5.3 we will do a similar analysis to 5.2 for the SD Method with modal filtering. One can see how the modal filtering leads to much better stability properties and how they depend on certain parameters like the order $p$ and $\alpha, \beta, \gamma$ from the APK polynomials.

5.1. Matrix representation. We already stated in Section 3 that the universal update scheme (3.3) at the cell $\tau_{i,j}$ reads

$$\frac{du_{i,j}^s(t)}{dt} = -(\xi_x D_\xi + \xi_y D_\eta)\mathcal{V}^{-1}F_1(t) - (\eta_x D_\xi + \eta_y D_\eta)\mathcal{V}^{-1}F_2(t),$$

(5.3)

when evaluated at the solution points. If we look at the cell $\tau_{0,0}$ and denote $\frac{du_{i,j}^s(t=0)}{dt}$ for the sake of simplicity by $\frac{du^s}{dt}$ equation (5.3) becomes

$$\frac{du^s}{dt} = -(D_\xi \mathcal{V}^{-1}F_1 + D_\eta \mathcal{V}^{-1}F_2),$$

(5.4)
since $\tau_{0,0}$ and its neighbors are parametrized by the orientation-preserving affine transformations

$$T_{0,0}(x, y) = \begin{pmatrix} x \\ y \end{pmatrix}, T_{-1,0}(x, y) = \begin{pmatrix} y \\ -x \end{pmatrix}, T_{0,-1}(x, y) = \begin{pmatrix} -y \\ x \end{pmatrix}, T_{0,1}(x, y) = \begin{pmatrix} 1-x \\ 1-y \end{pmatrix}.$$ 

Note that $F_1, F_2$ are given by (3.3), where the upwind flux is used and the flow direction was restricted to $\psi \in [0, \frac{\pi}{2}]$. Consequently $F_1, F_2$ are independent of the values from $\tau_{0,1}$ and so (5.4) now reads

$$\frac{d u^s}{d t} = -\cos(\psi) D_\xi V^{-1} \left[ M^{1,0}_1 u^f_{-1,0} + M^{0,0}_1 u^f_{0,0} + M^{0,-1}_1 u^f_{0,-1} \right]$$

$$- \sin(\psi) D_\eta V^{-1} \left[ M^{1,0}_2 u^f_{-1,0} + M^{0,0}_2 u^f_{0,0} + M^{0,-1}_2 u^f_{0,-1} \right].$$

Here the $M^{m,n}_i$ for the second-order SD Method, and so $K_F = \frac{(2+1)(2+2)}{2} = 6$, are

$$M^{1,0}_1 = e_1^T e_1 + e_2^T e_2 + e_3^T e_3, \quad M^{0,0}_1 = e_4^T e_5 + e_6 e_6, \quad M^{0,-1}_1 = e_4^T e_4,$$

$$M^{1,0}_2 = e_2^T e_2, \quad M^{0,0}_2 = e_3^T e_3 + e_4^T e_5, \quad M^{0,-1}_2 = e_1^T e_1 + e_4^T e_4 + e_6 e_6.$$

For the exact computation see [47, Chapter 3.3.1] and the $M^{m,n}_i$ for $N = 3, 4, 5$ can be found in the appendix. Next we can make use of the periodicity of the initial condition to get rid of $u^f_{-1,0}$ and $u^f_{0,-1}$ by substituting them by terms $T_{-1,0} u^f_{0,0}$ and $T_{0,-1} u^f_{0,0}$. Therefore, note that $u^f_{-1,0}, u^f_{0,0}$ and $u^f_{0,-1}$ are given by the initial condition. Hence

$$u^f_{0,0} = (u_{init}(T_{0,0}(\xi_k, \eta_k)))_k = (u_{init}(\xi_k, \eta_k))_k$$

$$=(e^{I(w_x \xi_k + w_y \eta_k)})_k,$$

$$u^f_{-1,0} = (u_{init}(T_{-1,0}(\xi_k, \eta_k)))_k = (u_{init}(-\eta_k, \xi_k))_k$$

$$=(e^{I(-w_x \eta_k + w_y \xi_k)})_k = (e^{I(-w_x(\xi_k + \eta_k) - w_y(\xi_k - \eta_k))})_k$$

$$=T_{-1,0} u^f_{0,0},$$

$$u^f_{0,-1} = (u_{init}(T_{0,-1}(\xi_k, \eta_k)))_k = (u_{init}(\eta_k, -\xi_k))_k$$

$$=(e^{I(w_x \eta_k - w_y \xi_k)})_k = (e^{I(w_x(\eta_k - \xi_k) - w_y(\xi_k - \eta_k))})_k$$

$$=T_{0,-1} u^f_{0,0},$$

with

$$T_{-1,0} := \sum_k e^{I(-w_x(\xi_k + \eta_k) + w_y(\xi_k - \eta_k))} e_k^T e_k,$$

$$T_{0,-1} := \sum_k e^{I(w_x(\eta_k - \xi_k) - w_y(\xi_k + \eta_k))} e_k^T e_k,$$

and we obtain

$$\frac{d u^s}{d t} = -\left[ \cos(\psi) D_\xi V^{-1} \left[ M^{1,0}_1 T_{-1,0} + M^{0,0}_1 T_{0,-1} \right] u^f_{0,0} \right] + \sin(\psi) D_\eta V^{-1} \left[ M^{1,0}_2 T_{-1,0} + M^{0,0}_2 + M^{0,-1}_2 T_{0,-1} \right] u^f_{0,0}. \tag{5.5}$$

Last, we want to write $u^f_{0,0}$ in terms of $u^s_{0,0}$ or just $u^s$ to obtain a relation as in (5.2). While we reconstructed the flux $F$ by APK polynomials, in order to later
use their natural filter given by (4.10), we reconstruct the solution \( u \) by Lagrange polynomials. Hence

\[
\begin{align*}
\mathbf{u}_{0,0}^f &= \left( \sum_{k=1}^{K_F} u_{0,0}(x_k^f) L_k(T_{0,0}(x_j^f)) \right)_{j=1}^{K_F} \\
&= E_{\text{Lag}} \mathbf{u}^s
\end{align*}
\]

with \( E_{\text{Lag}} := (L_k(x_j^f))_{j,k} \in \mathbb{R}^{K_F \times K_S} \). If we use this in (5.5), we finally obtain

\[
\frac{d \mathbf{u}^s}{dt} = -\left( \cos(\psi) \partial_{x^3} \mathcal{V}^{-1} \left[M_1^{-1,0} T_{-1,0} + M_1^{0,0} + M_1^{0,-1} T_{0,-1} \right] \\
+ \sin(\psi) \partial_{y^3} \mathcal{V}^{-1} \left[M_2^{1,0} T_{-1,0} + M_2^{0,0} + M_2^{0,-1} T_{0,-1} \right] \right) E_{\text{Lag}} \mathbf{u}^s,
\]

which we want to retain in the following lemma.

**Lemma 5.1.** For a linear advection equation with flow direction \( \psi \in [0, \frac{\pi}{2}] \) and periodic initial condition \( u_{\text{init}} \) on a triangular grid as in Figure 3, where the full upwind is used, the universal update scheme (3.3) on \( \tau_{0,0} \) reads

\[
\frac{d \mathbf{u}^s}{dt} = S \mathbf{u}^s
\]

with semi-discretization \( S \) given by

\[
S := -\left( \cos(\psi) \partial_{x^3} \mathcal{V}^{-1} \left[M_1^{-1,0} T_{-1,0} + M_1^{0,0} + M_1^{0,-1} T_{0,-1} \right] \\
+ \sin(\psi) \partial_{y^3} \mathcal{V}^{-1} \left[M_2^{1,0} T_{-1,0} + M_2^{0,0} + M_2^{0,-1} T_{0,-1} \right] \right) E_{\text{Lag}}.
\]

We already stated in Section 4 that the universal update scheme (3.3) with modal filtering at the cell \( \tau_{i,j} \) reads

\[
\frac{d \mathbf{u}^s_{i,j}(t)}{dt} = -\left( \xi_x \partial_{x^3} + \xi_y \partial_{y^3} \right) M_3 \mathcal{V}^{-1} \mathbf{F}_1(t) \\
- (\eta_x \partial_{x^3} + \eta_y \partial_{y^3}) M_3 \mathcal{V}^{-1} \mathbf{F}_2(t),
\]

when evaluated at the solution points. If we combine this with Lemma 5.1, we obtain a similar corollary for the the filtered SD Method.

**Corollary 5.2.** For a linear advection equation with flow direction \( \psi \in [0, \frac{\pi}{2}] \) and periodic initial condition \( u_{\text{init}} \) on a triangular grid as in Figure 3, where the full upwind is used, the universal update scheme with modal filtering on \( \tau_{0,0} \) reads

\[
\frac{d \mathbf{u}^s}{dt} = \mathbf{u}^s
\]

with semi-discretization \( S_3 \) given by

\[
S_3 := -\left( \cos(\psi) \partial_{x^3} M_3 \mathcal{V}^{-1} \left[M_1^{-1,0} T_{-1,0} + M_1^{0,0} + M_1^{0,-1} T_{0,-1} \right] \\
+ \sin(\psi) \partial_{y^3} M_3 \mathcal{V}^{-1} \left[M_2^{1,0} T_{-1,0} + M_2^{0,0} + M_2^{0,-1} T_{0,-1} \right] \right) E_{\text{Lag}}.
\]
Algorithm 1 without filtering

1: for $\alpha, \beta = 0.1 : 0.1 : 2, \gamma = \alpha + \beta : 0.1 : 6$ do
2:   $L << 0$ (e.g. $-42$)
3:   for $\psi = 0 : \frac{\pi}{8} : \frac{\pi}{2}, w_x, w_y = -\pi : \frac{\pi}{2} : \pi$ do \hfill $\triangleright$ test cases
4:       compute $S$
5:       $v = \text{eig}(S)$
6:       $v_{re} = \text{real}(v)$
7:       $\Lambda = \max(v_{re})$
8:   if $\Lambda > L$ then
9:     $L = \Lambda$
10: return $(\alpha, \beta, \gamma, L)$ \hfill $\triangleright$ $L$ is the greatest real part

5.2. Stability analysis for the SD method. We already stated that the asymptotic behavior of the solution of (5.2) depends on the real parts of the eigenvalues of $S \equiv S(\alpha, \beta, \gamma)$ given by (5.6). For linear stability, we wish them to lie in the left half of the complex plane. In case there are no such parameters $\alpha, \beta \in \mathbb{R}^+$ and $\gamma > \alpha + \beta - 1$, we want at least to find a set of parameters $(\alpha, \beta, \gamma)$ with preferably small real parts. If we denote the maximal real part over all eigenvalues corresponding to a certain parameter set $(\alpha, \beta, \gamma)$ and a fixed set of test cases with respect to $w_x, w_y, \psi$ by $\Lambda \equiv \Lambda(\alpha, \beta, \gamma)$, this leads to the optimization problem

\[
\arg \min_{\alpha, \beta \in \mathbb{R}^+, \gamma > \alpha + \beta - 1} \Lambda(\alpha, \beta, \gamma).
\]

Note that this is a continuous and nonconvex problem. Future studies could give a strict treatment of the optimization problem (5.9), but since we just want to demonstrate the influence of the chosen polynomial basis on the stability of the SD Method with and without modal filtering, we will just concentrate on certain subranges for $\alpha, \beta$ and $\gamma$. In the following, we will concentrate on the subrange of

\[
P := \{(\alpha, \beta, \gamma) \mid \alpha, \beta = 0.1, 0.2, \ldots, 2 \text{ and } \gamma = \alpha + \beta, \alpha + \beta + 0.1, \ldots, 6\}
\]

due to the observation that higher parameters lead to much worse condition numbers; see Table I. For a fixed parameter set $(\alpha, \beta, \gamma)$ in such a subrange we will compute all eigenvalues of $S$ and look for the one with the greatest real part. This will be done for several test cases with respect to the flow direction $\psi \in [0, \frac{\pi}{2}]$ and the wave numbers $w_x, w_y \in [-\pi, \pi]$. Then we will again look after the greatest real part among all of these test cases. The resulting eigenvalue and its real part will be taken as an evidence for the stability of the underlying parameter set $(\alpha, \beta, \gamma)$ and its corresponding polynomial basis. All of this is done in MatLab, where a descriptive pseudo code is given by Algorithm 1. The numerical results show that the maximal real part of all eigenvalues $L$ is independent of $\alpha, \beta$ and $\gamma$. Hence the linear stability is independent of the corresponding basis of APK polynomials, which coincides with the following theorem.

**Theorem 5.3.** In Lemma 5.1 the eigenvalues of the semi-discretization $S$, given by (5.6), are independent of the basis of APK polynomials corresponding to $\alpha, \beta$ and $\gamma$.

**Proof.** Looking at $S$, only the differential matrices $D_\xi, D_\eta$, given by (3.5), and the Vandermonde matrix $\mathcal{V}$, coming from the interpolation approach, depend on the
underlying basis \( \{ \phi_k \mid 1 \leq k \leq K_F \} \) of \( \mathbb{P}_N(\mathbb{T})^2 \). Hence the proof is done, when we can eliminate these matrices from \( S \). Therefore note that
\[
D_\xi = \left( \partial_\xi \phi_k \left( T_{0,0} \left( x_j^s \right) \right) \right)_{j,k}^{K_x, K_F} = \left( \partial_\xi \phi_k (x) \mid x = x_j^s \right)_{j,k}
\]
\[
= \left( \partial_\xi \left[ \sum_{i=1}^{K_F} \phi_k \left( x_i^F \right) L_i (x) \right] \mid x = x_j^s \right)_{j,k}
\]
\[
= \left( \sum_{i=1}^{K_F} \phi_k \left( x_i^F \right) \partial_\xi L_i (x) \mid x = x_j^s \right)_{j,k}
\]
\[
= \left( \partial_\xi L_i (x)^s \right)_{j,i}^{K_x, K_F} \cdot \left( \phi_k \left( x_i^F \right) \right)_{i,k}
\]
\[
= D_\xi^{\text{Lag}} \psi
\]
and analogous \( D_\eta = D_\eta^{\text{Lag}} \psi \) with
\[
D_\xi^{\text{Lag}} := \left( \partial_\xi L_i (x_j^s) \right)_{j,i}^{K_x, K_F}, \quad D_\eta^{\text{Lag}} := \left( \partial_\eta L_i (x_j^s) \right)_{j,i}^{K_x, K_F}
\]
independent of the basis \( \{ \phi_k \} \). Hence
\[
D_\xi \psi^{-1} = D_\xi^{\text{Lag}}, \quad D_\eta \psi^{-1} = D_\eta^{\text{Lag}}
\]
and
\[
S = \left( \cos(\psi) D_\xi^{\text{Lag}} \left[ M_1^{-1,0} T_{-1,0} + M_1^{0,0} + M_1^{0,-1} T_{0,-1} \right] \right.
\]
\[
+ \sin(\psi) D_\eta^{\text{Lag}} \left[ M_2^{-1,0} T_{-1,0} + M_2^{0,0} + M_2^{0,-1} T_{0,-1} \right] \big) E_{\text{Lag}}
\]
is independent of the underlying basis \( \{ \phi_k \} \). \( \square \)

Note that we have done the proof for an arbitrary basis \( \{ \phi_k \} \) of \( \mathbb{P}_N(\mathbb{T})^2 \) and, moreover, that by \( \text{(5.10)} \) the more general universal update scheme \( \text{(3.7)} \) for a general (nonlinear) conservation law becomes
\[
\frac{du^s}{dt} (t) = - \left( \xi_x D_\xi^{\text{Lag}} + \xi_y D_\eta^{\text{Lag}} \right) \mathbf{F}_1 (t) - \left( \eta_x D_\xi^{\text{Lag}} + \eta_y D_\eta^{\text{Lag}} \right) \mathbf{F}_2 (t)
\]
with \( \mathbf{F}_1 (t), \mathbf{F}_2 (t) \) independent of the basis \( \{ \phi_k \} \), when we use an interpolation approach to reconstruct the flux. This leads to the following corollary.

**Corollary 5.4.** The SD Method (without filtering) with an interpolation approach is independent of the underlying polynomial basis.

**Remark 5.5.** While the SD Method with an interpolation approach theoretically is independent of the underlying polynomial basis, in computation their condition properties may have an influence on the resulting scheme; see Table 1. By substituting \( D_\xi \) by \( D_\xi^{\text{Lag}} \) and \( D_\eta \) by \( D_\eta^{\text{Lag}} \) and working with \( \text{(5.11)} \) in our implementation, we block out condition properties of the underlying basis and just focus on the pure stability properties of the SD Method. However, one should note that this won’t be the case in the next subsection, where the Vandermonde matrix and its inverse will not cancel out each other. Then, to cover condition issues as well, we focus on a proper subrange of parameters which will ensure good condition numbers. In such a subrange we then will optimize the linear stability of the SD Method.

Table 6 shows the maximal real parts among all test cases for certain orders $N$. These values show that the SD Method on triangles is not stable, independent of the polynomial basis in the interpolation approach. This was already stated by Van den Abeele, Lacor and Wang in [40]. As one can see in Table 6 the instabilities, i.e., $\text{Re}(\lambda)$, of the method can be “quite high”. To deal with this problem we will apply the modal filter in the SD Method in the next section.

5.3. Numerical stability analysis for the SD method with modal filtering.

As we proposed in Section 4, we use the SV Method seen as a spectral method with modal filtering to obtain milder instabilities in the von Neumann analysis and hence preserving the scheme to blow up at discontinuities. While we used $D V^{-1} = D^{\text{Lag}}$ in Section 5.2 to show that the SD Method is independent of the underlying basis this term becomes

$$D M_\sigma V^{-1}$$

in the semi-discretization $S_\sigma$, given by (5.3), for the SD Method with modal filtering. This again leads to $S_\sigma \equiv S_\sigma(\alpha, \beta, \gamma)$ and the method to depend on the corresponding basis of APK polynomials. Following Section 5.2 we use Algorithm 1 with $S = S_\sigma$ for a (linear) stability analysis for the SD Method with modal filtering. But first, note that the values of the modal filter $\sigma$ in the filter matrix $M_\sigma := \text{diag}(\sigma_1,\ldots,\sigma_K)$ depend on certain constants, which were explained in Section 4.2. For the following numerical results we set

$$h = \frac{\sqrt{2}}{6}, \quad \text{see (4.13)},$$

$$C_{\text{fix}} = \frac{1}{2}, \quad \lambda_{\text{max}} = 1, \quad \text{see (4.14)}.$$

For order $N = 3$, different orders $p \in \mathbb{N}_0^5$ and constants $c \in \mathbb{N}_0^2$ in the filter strength (4.13), Tables 7, 8 and 9 show the smallest real parts $L$ (maximum over all test cases) and their corresponding parameters $(\alpha, \beta, \gamma) \in P$.

We can see in Tables 7–9 that one can obtain much milder instabilities of the method by modal filtering, where also the choice of family of APK polynomials for the underlying basis of $\mathbb{P}_N(T)^2$ has an influence. Note that in fact both $p$, $c$ and every parameter $\alpha$, $\beta$ and $\gamma$ effect the linear stability. Approximately, the parameter tuples $(1, 1, 6)$ and $(2, 2, 5)$ appear promising. However, by considering their conditional numbers in Table 1 the parameter tuple $(1, 1, 6)$ becomes unreasonable, due to its high condition numbers. Thus, we will focus on parameter tuple $(2, 2, 5)$ in the following example which will help us to find suitable choices for the parameter $c$ and the filter order $p$.

</table>
Example 5.6. First, we observe that the constant \(c\) has an influence on the linear stability by comparing the parameter tuple \((2, 2, 5)\) for \(N = 3, p = 2\) and different \(c\). In this case we have

\[
L = 2.502205e + 00 \text{ for } c = 2,
\]
\[
L = 2.000045e + 00 \text{ for } c = 3,
\]
\[
L = 1.824525e + 00 \text{ for } c = 4,
\]
\[
L = 1.639219e + 00 \text{ for } c = 5,
\]
\[
L = 1.459258e + 00 \text{ for } c = 6,
\]
\[
L = 1.290925e + 00 \text{ for } c = 7,
\]
\[
L = 1.135887e + 00 \text{ for } c = 8,
\]

which indicates that by increasing parameter \(c\) the instability gets milder. This coincides with Theorem 4.3 which states the equivalence of modal filtering by our natural filters and the SV Method. In this formulation \(c\) is proportional to \(\varepsilon_N\) (see (4.13)), which again is proportional to the dissipation we add to the underlying conservation law by the viscosity term.

In the same way, by comparing the parameter tuple \((2, 2, 5)\) for \(N = 3\) and \(c = 8\), we can observe the influence of the parameter \(p\). Here

\[
L = 1.406930e + 00 \text{ for } p = 1,
\]
\[
L = 1.35887e + 00 \text{ for } p = 2,
\]
\[
L = 1.227645e + 00 \text{ for } p = 3,
\]
\[
L = 1.481018e + 00 \text{ for } p = 4,
\]
\[
L = 1.593715e + 00 \text{ for } p = 5,
\]

suggest \(p = 2\) to be the best choice.

Finally, we observe the influence of the parameter \(\gamma\) by comparing parameter tuples \((2, 2, \gamma)\) for \(N = 3, c = 8\) and \(p = 2\). Here

\[
L = 1.284659e + 00 \text{ for } \gamma = 4,
\]
\[
L = 1.212759e + 00 \text{ for } \gamma = 4.5,
\]
\[
L = 1.135887e + 00 \text{ for } \gamma = 5,
\]
\[
L = 1.200003e + 00 \text{ for } \gamma = 5.5,
\]
\[
L = 1.216268e + 00 \text{ for } \gamma = 6,
\]

show the influence.

The natural filter of \((1,1,2)\), the one of \((2,2,5)\) and the shaped raised cosine filter of eighth order can be seen and compared in Figure 4.

We end this section by recommending the parameter tuple \((\alpha, \beta, \gamma) = (2, 2, 5)\) with \(c = 8\) and filter order \(p = 2\) for the polynomial degree \(N = 3\). The following section will provide numerical test which build around this choices.

6. Numerical tests

After presenting our theoretical results we want to give a short numerical investigation to show that our conclusions are justified. We consider the two-dimensional Burgers’ equation

\[
u_t(x, y, t) + u(x, y, t)(u_x(x, y, t) + u_y(x, y, t)) = 0
\]
in the domain $[-1,1]^2$ with the initial condition

$$u_0(x,y) = \frac{1}{4} + \frac{1}{2} \sin(\pi(x+y))$$

and periodic boundary conditions $u(-1,y,t) = u(1,y,t)$ and $u(x,-1,t) = u(x,1,t)$. At $t = 0.5s$ two discontinuities arise at $y = \frac{3}{2} - x$ and $y = \frac{5}{2} - x$. We use 1088 triangles for the spatial discretization and present the numerical solutions at $t = 0.45s$ for several parameter selections. Without filtering high oscillations already developed in much earlier calculations and the SD Method collapses.

In Tables 10 and 11 the minimum and maximum of the numerical solutions for filter parameters $p$ and $c$ are shown in the polynomial cases $(\alpha, \beta, \gamma) = (1,1,2)$ and $(2,2,5)$. These values give a first indication for the stability of the resulting method.
The polynomial degree $N$ in these test cases is always three. For most parameters $p$, $c$ and $(\alpha, \beta, \gamma)$, we were not able to calculate in time further than 0.45s. However, for the choice $p = 2$ and $c = 8$ motivated by our stability analysis we were indeed able to calculate up to 0.45 for both parameters $(1, 1, 2)$ and $(2, 2, 5)$. In Figure 5 the 2d and 3d plots of the numerical solutions are presented. No post-processing was applied.

Predicted by the stability analysis in Section 5 and coinciding with Tables 10 and 11, the selection of parameters $p = 2$ and $c = 8$ using the APK polynomials $(2, 2, 5)$ and their natural filters show significantly stronger stability properties than for instance $(1, 1, 2)$. Here, two attributes play a key role in the calculation. First $(2, 2, 5)$ has a small condition number; see Table 1. But second and more important are the good properties—using the natural filter with $\gamma = 5$—from the point of linear stability, suggested by the stability analysis in Section 5. Following this observation, we wish to combine a small condition number like for $(1, 1, 2)$ and the good stability of the choice $(\alpha, \beta, \gamma) = (2, 2, 5)$ with $p = 2$ and $c = 8$. Therefore we next observed the polynomial basis of $(1, 1, 2)$, however, equipped with the natural filter of $(2, 2, 5)$ instead of its own. That is, we choose $\gamma = 5$ in (4.10) instead of the natural choice $\gamma = 2$. The resulting numerical solutions, again presented in 2d and 3d plots, can be seen in Figure 6 and once more show an improvement.

\begin{table}[h]
\centering
\caption{$(\alpha, \beta, \gamma) = (2, 2, 5)$, $t = 0.45s$}

APPLICATION OF MODAL FILTERING TO AN SD METHOD

Figure 6. \((\alpha, \beta, \gamma) = (1, 1, 2)\) with the natural filter of \(p = 2\), \(c = 8\) and \((2, 2, 5)\)

7. Discussion and conclusion

We started this paper by extending the SD Method by more general bases of APK polynomials instead of Lagrange or PKD polynomials and instantly observed their numerical qualification by their condition numbers. The classical SD method was known to be unstable on triangular elements and unfortunately we were able to obtain the same result for every extended version of the SD Method. Hence addressing the problem of Gibb’s phenomenon, which often leads unstable schemes to blow up, we applied the well-known SV Method to milder instabilities. Due to the APK polynomials to fulfill certain eigenvalue problems, we derived an equivalent but from the point of computational costs a much more efficient formulation of the SV Method via modal filtering by natural exponential filters with respect to the polynomial basis. Whole new error estimates for filtered APK extensions for smooth functions were then given. We also gave a von Neumann analysis for linear stability for the extended SD method with modal filtering by natural filters of APK polynomials. The idea was for the right choice of APK polynomials to have some positive influence on the stability and accuracy of the method. To the best of our knowledge, this work was the first to give such an analysis for a scheme with spectral filtering. This stability analysis indeed suggested a certain choice of APK polynomials and parameters in their natural filters, which then were observed in a short numerical investigation. The numerical solutions we obtained showed significantly stronger stability properties than the ones resulting from classical SD Methods. By combining our results from the analysis of condition numbers and linear stability for different APK polynomials, we equipped basis polynomials with favorable condition numbers with modal filters coming from a polynomial basis with strong stability properties. Once more, this led to a significant improvement of the numerical solutions.

Despite this, it should also be said that Flux Reconstruction (FR) or Correction Procedure via Reconstruction (CPR) methods nowadays are getting more and more interesting, due to their strong stability properties, while SD methods are receiving decreasing attention. We still analyzed modal filtering based on SD methods to
investigate the pure influence of the orthogonal polynomials and their natural filters. In the FR/CPR approach a correction term is applied which might cancel out effects of the filter. However, the observations made for spectral filtering in this paper target a first step to both a better understanding of the influence of spectral filtering and in the future to gainfully adapt these ideas to FR/CPR methods. Improvements might be higher CFL numbers, thus larger time steps and more efficient methods, as well as more advanced methods in post-processing.

In future research further developments for modal filtering itself would be favorable. Due to high condition numbers of the Vandermonde matrix for several bases of APK polynomials, we had to restrict ourselves to certain subranges of parameter families. However, it could be possible to find filters with even better properties outside of these subranges. To bypass the problem of quite bad condition numbers in these new ranges, it would be promising to work with projection approaches in the series expansion, instead of interpolation ones.

8. Appendix

$M_i^{m,n}$ for the SD Method of third order ($K_s = 6, K_F = 10$):

$M_1^{-1,0} = \text{diag}(E_{4\times4}, 0_{6\times6}),$

$M_1^{0,0} = \text{diag}(0_{5\times5}, E_{2\times2}, 0_{1\times1}, E_{2\times2}),$

$M_1^{0,-1} = \text{diag}(0_{4\times4}, E_{1\times1}, 0_{2\times2}, E_{1\times1}, 0_{2\times2}),$

$M_2^{-1,0} = \text{diag}(0_{1\times1}, E_{2\times2}, 0_{7\times7}),$

$M_2^{0,0} = \text{diag}(0_{3\times3}, E_{1\times1}, 0_{1\times1}, E_{2\times2}, 0_{1\times1}, E_{1\times1}, 0_{1\times1}),$

$M_2^{0,-1} = \text{diag}(E_{1\times1}, 0_{3\times3}, E_{1\times1}, 0_{2\times2}, E_{1\times1}, 0_{1\times1}, E_{1\times1}).$

$M_i^{m,n}$ for the SD Method of fourth order ($K_s = 10, K_F = 15$):

$M_1^{-1,0} = \text{diag}(E_{5\times5}, 0_{10\times10}),$

$M_1^{0,0} = \text{diag}(0_{6\times6}, E_{3\times3}, 0_{1\times1}, E_{2\times2}, 0_{1\times1}, E_{2\times2}),$

$M_1^{0,-1} = \text{diag}(0_{5\times5}, E_{1\times1}, 0_{3\times3}, E_{1\times1}, 0_{2\times2}, E_{1\times1}, 0_{2\times2}),$

$M_2^{-1,0} = \text{diag}(0_{1\times1}, E_{3\times3}, 0_{11\times11}),$

$M_2^{0,0} = \text{diag}(0_{4\times4}, E_{1\times1}, 0_{1\times1}, E_{3\times3}, 0_{1\times1}, E_{2\times2}, 0_{1\times1}, E_{1\times1}, 0_{1\times1}),$

$M_2^{0,-1} = \text{diag}(E_{1\times1}, 0_{4\times4}, E_{1\times1}, 0_{3\times3}, E_{1\times1}, 0_{2\times2}, E_{1\times1}, 0_{1\times1}, E_{1\times1}).$

$M_i^{m,n}$ for the SD Method of fifth order ($K_s = 15, K_F = 21$):

$M_1^{-1,0} = \text{diag}(E_{6\times6}, 0_{15\times15}),$

$M_1^{0,0} = \text{diag}(0_{7\times7}, E_{4\times4}, 0_{1\times1}, E_{3\times3}, 0_{1\times1}, E_{2\times2}, 0_{1\times1}, E_{2\times2}),$

$M_1^{0,-1} = \text{diag}(0_{6\times6}, E_{1\times1}, 0_{4\times4}, E_{1\times1}, 0_{3\times3}, E_{1\times1}, 0_{2\times2}, E_{1\times1}, 0_{2\times2}),$

$M_2^{-1,0} = \text{diag}(0_{1\times1}, E_{4\times4}, 0_{16\times16}),$

$M_2^{0,0} = \text{diag}(0_{5\times5}, E_{1\times1}, 0_{1\times1}, E_{4\times4}, 0_{1\times1}, E_{3\times3}, 0_{1\times1}, E_{2\times2}, 0_{1\times1}, E_{1\times1}, 0_{1\times1}),$

$M_2^{0,-1} = \text{diag}(E_{1\times1}, 0_{5\times5}, E_{1\times1}, 0_{4\times4}, E_{1\times1}, 0_{3\times3}, E_{1\times1}, 0_{2\times2}, E_{1\times1}, 0_{1\times1}, E_{1\times1}).$
